As shown in Table 6, independent sample *t*-test results showed that there is a significant difference in the disposition towards critical thinking between science and non-science rural secondary students in the Interior Division of Sabah ($t = 2.739$, $p = .006$). In relation to this, science students are more disposed towards critical thinking compared to their counterparts: 'truth-seeking' ($t = 2.857$, $p = .004$), 'open-mindedness' ($t = 4.633$, $p < .0005$), and 'analyticity'

(t = 2.976, p = .003). Hence, these findings had successfully rejected the second null hypothesis.

Table 7 shows the percentages of science and non-science students according to scale scores and overall scores of disposition towards critical thinking.

Table 7: Percentages of Science and Non-Science Students according to Scale Scores of Disposition towards Critical Thinking

CCTDI Subscales	Science			Non-Science		
	10-30 Negative Disposition	31-39 Ambivalent Disposition	40-60 Positive Disposition	10-30 Negative Disposition	31-39 Ambivalent Disposition	40-60 Positive Disposition
Truth-Seeking	.5	34.0	65.5	4.9	37.9	57.1
Open-Mindedness	0	0	100.0	.5	6.6	92.9
Analyticity	1.0	16.8	82.1	2.9	19.5	77.6
CT Self-Confidence	1.0	11.7	87.2	0	10.1	89.9
Inquisitiveness	7.1	65.2	27.8	8.9	58.9	32.2
Maturity	.5	12.1	87.4	0	13.2	86.8
	Science			Non-Science		
	<280 Negative Disposition	281-349 Ambivalent Disposition	350> Postive Disposition	<280 Negative Disposition	281-349 Ambivalent Disposition	350> Positive Disposition
Overall	15.8	82.5	1.8	12.9	86.7	.4

One of the possible explanations for this observation is that science students are given more opportunities and exposure to inquiry and problem-based learning as compared to non-science students. During inquiry-based learning, students are required to critically evaluate their own thought process in formulating a hypothesis, planning an experiment, collecting data, analyzing and interpreting data, and making a conclusion. Hence, the inquiry-based learning environment enhance students' disposition towards critical thinking.

CONCLUSION

Generally, this study found that Form 4 rural secondary students in the Interior Division of Sabah are ambivalently disposed towards critical thinking. Students are ambivalently disposed towards 'CT self-confidence' and 'maturity'. However, students are positively disposed towards 'open-mindedness', 'systematicity', 'inquisitiveness', 'analyticity', and 'truth-seeking'. This study also found a significant difference in the disposition toward critical thinking based on types of classes attended. Generally, science students are more disposed towards critical thinking than their counterparts in 'truth-seeking', 'open-mindedness', and 'analyticity'. However, the differences in the disposition towards 'systematicity', 'CT self-confidence', 'inquisitiveness', and 'maturity' are not statistically significant. Hence, those who are involved directly or indirectly in the planning and implementation of science curriculum need to plan effective intervention programs to enhance students' disposition towards critical thinking in an effort to improve rural secondary students' science achievement. These follow-up efforts are crucial to ensure that our nation's vision to establish a science and technology-based society will become reality.

Valerie Fontanieu — INRP Lyon

ABSTRACT

The purpose of this study is to investigate the attitudes towards environment in the population of French students. We analyse the results of the questionnaire-based relevance of Science Education Project carried out in France in 2008 as a part of a wider international comparative study ROSE. The hierarchical ascendant classification of data from 2124 French students, led to three main classes, showing a high resonance, with the three main attitudes toward environment: egocentrism, anthropocentrism, and ecocentrism. The findings reveal significant gender effect in these three classes. Our data suggest that there are links between the three different attitudes toward environment and students' level of interest in learning about environmental topics. More, we could relate the three classes to the practice frequency of some specific out-of-school activities. Our data suggest that environmental attitudes are linked to environmentally-relevant behaviors.

***Keywords**: environment, attitudes, gender, ROSE project, , out-of-school activities*

BACKGROUND, FRAMEWORK AND PURPOSE

Science education has a key role in preparing young people to cope and to deal with responsibility emerging from environmental challenges.

Proposing two different views of Scientific Literacy, Roberts (2007) refers to the role of two legitimate but potentially conflicting curriculum sources: science subject matter itself, or situations in which science can legitimately be seen to play a role in other humans affairs. In this last perspective, environmental education is a key element of the scientific literacy, since it exemplifies science in context, in local environments and the daily life of people. Some argue that science education's role is to provide a set of skills and knowledge to be learned by students, who will decide themselves how to apply these competences, avoiding any risk of indoctrination. Others as for example Östman (2007) argue that science education needs to involve ethical as well as political reasoning. Failing to meet this challenge will mean that we run the risk of making students blind to the socialization to which they have been exposed. We will also miss the opportunity to make science education relevant.

As Jenkins (2002) and Layton et al. (1993) have shown, scientific knowledge will only become useful in everyday life when this knowledge interacts with economic, social and cultural aspects of life.

Developing students' knowledge and awareness of environmental issues has never been such an important goal of science education than now. But this teaching must be based on knowledge of students' attitudes to the environmental protection issue (Schreiner and Sjoberg, 2005). Diversity in humans' traditions, religious and spiritual approaches, philosophical directions may lead to different views of nature and environment, and consequently to diverse motivation and attitudes toward environment (Cooper & Palmer, 1998).

Environmental attitudes (EA) have been defined as « the collection of beliefs, affect, and behavioural intentions a person holds regarding environmentally related activities or issues » (Schultz et al., 2004). A pro-environmental attitude may result from different motivations that could have very different implications for behaviour and cognitive process. Several theories have categorized environmental values in similar ways : for instance, homocentric, ecocentric and egocentric values (Merchant, 1990) corresponding respectively to social-altruistic, biospheric and egoistic values according to Stern & Dietz (1994), and to anthropocentric versus ecocentric values (e.g. Thompson and Barton, 1994). The dimensionality of environmental attitudes and the nature of the dimensions are still discussed (e.g. Munoz et al., 2009).

The egocentric value is self-centred. It is based on an individual ought focused on individual good. It reflects the belief that what is good for the individual will benefit society.

Both ecocentric and anthropocentric individuals express positive attitudes toward environmental issues but not for the same reasons.

Anthropocentrics consider human to be the most important life form, and other forms of life to be important only to the extent that they affect humans or can be useful to humans. They feel that the environment should be protected because of its utilitarian value in maintaining or enhancing the quality of life for the largest number of people.

Ecocentric individuals assign intrinsic value to the whole environment, including animate and inanimate elements. The ecosystem intrinsic value is a sufficient reason for protecting it.

Our study takes place in an international survey project ROSE « Relevance of Science Education » developed by S. Sjoberg (http://www.ils.uio.no/english/rose). This project was designed to gather information about students' opinions of school science and science-related issues in general, including environment issues, and several other factors that have a bearing on their attitudes to science and technology and their motivation to learn science and technology. More than 40 countries are involved in this project, we led this international survey in France.

The main purpose of this study is to investigate the attitudes towards environment in the population of 15 year old French students. Do the French students feel interested and engaged in the environmental issues? What are the reasons of their involvement? Is there any link between French students' environmental attitudes and their interest to learn environment-related topics? May this engagement be linked to specific out-of-school activities?

METHODOLOGY

The questionnaire ROSE (downloadable from http://www.ils.uio.no/english/rose) written in English consists of 250 items, most of which are divided into 7 item groups : « my out-of-school experiences », « what I want to learn about », « my future job », « Me and the environment », « my science classes », « my opinions about science and technology » and « myself as a scientist ». For the French version, we added 43 background questions concerning home as well as questions concerning attitudes about taught sciences (mainly derived from the OECD Programme for Student Assessment PISA questionnaire) « Me and my strategy for learning Sciences », « Me and my family about technologies and Sciences », « Me and my confidence in my work in sciences ». The questionnaire mostly consists of closed questions with four-point Likert scale.

The ROSE target population in France was the cohort of 15 years old French pupils, living in our country in 2007. In order to obtain a sample representative of the disparities in French schools, the French Ministry of Education chose randomly 126 different schools in the data base, taking into account different criteria such as secondary school/high school (as repeating a year is common in France); Private/public, etc… All the schools did the questionnaire on line. The data were collected on a server using the software Modalisa. 104 schools answered and we obtained 2124 filled questionnaires. In our study, 51,7% of answers are from girls, 48,3% from boys. We applied statistical corrections to restore the statistical representativeness of the 104 responding schools.

In this present article, we focused mainly on students' answers to the questions about environment. Students were invited to indicate their degree of agreement using a four-point Likert-type scale to 18 statements about environmental problems.

Using the software SPAD (http://eng.spad.eu), we proceed to a hierarchical ascendant classification from factorial axes determined with a multiple factorial analysis according to Camiz and Pagès (2005).

RESULTS AND ANALYSIS

Table 1 presents the descriptive statistics summarizing the responses to the 18 statements relating to « Me and the environmental challenges ». French data are consistent with the international results showing a similar pattern of responses as in the other industrialized countries (Trumper, 2009). Those, compared to developing countries, have a lower level of concern for an involvement in environmental problems and interest in learning environmental topics.

Statement	Dis.	L. Dis.	L. Ag.	Agree	No op	Nil resp
1. Threats to environment are not my business	51,0	33,9	8,0	3,2	3,4	0,5
2. Environmental problems make the future of the world look bleak	11,1	25,3	36,6	16,3	8,9	1,8
3. Environmental problems are exaggerated	20,5	40,4	22,6	6,6	8,2	6,6
4. Science and technology can solve all environmental problems	17,4	43,7	20,8	7,0	9,5	1,6
5. I am willing to have environmental problems solved even if this means sacrificing many goods	6,2	13,6	47,8	23,1	8,1	1,2
6. I can personally influence what happens with the environment	12,1	22,3	39,9	13,4	11,3	1,1
7. We can still find solutions to our environmental problems	3,6	7,6	51,9	30,5	5,0	1,3
8. People worry too much about environmental problems	25,0	39,2	19,8	7,5	7,3	1,2
9. Environmental problems can be solved without big changes in our way of living	19,7	34,2	27,3	8,2	9,0	1,6
10. People should care more about protection of the environment	2,2	4,0	39,4	49,4	3,9	1,0
11. It is the responsibility of the rich countries to solve the environmental problems of the world	18,8	31,1	25,9	13,5	9,4	1,3
12. I think each of us can make a significant contribution to environmental protection	3,1	5,4	39,8	46,9	4,0	0,8
13. Environmental problems should be left to the experts	30,0	41,1	13,9	5,9	7,8	1,3
14. I am optimistic about the future	10,5	21,1	37,1	13,7	15,8	1,7
15. Animals should have the same right to life as people	12,1	19,8	30,3	21,7	15,3	0,9
16. It is right to use animals in medical experiments if this can save human lives	25,4	21,4	27,0	10,2	15,1	0,9
17. Nearly all human activity is damaging to the environment	8,3	29,8	34,7	13,4	12,1	1,6
18.The natural world is sacred and should be left in peace	3,4	8,0	39,1	39,1	9,6	1,0

Table 1 : Students' responses (in percentage) about environmental challenges (Dis= Disagree ; L. Dis. : Low Disagree ; L. Ag : Low Agree ; Ag : Agree)

As written above, we proceed to a hierarchical ascendant classification using the responses to the 18 statements about environmental problems. It led to four main classes. In Table 2, for some examples of the 18 statements relating to « Me and the environmental challenges », we reported modalities characterizing the three main classes 1, 2 and 3. We considered that a modality was a characteristical feature for a class when p-value (reported in table 2) < 0,001. For instance individuals in class 1, chose modalities reflecting lack of concern for environmental issues and a general belief that problems in this area have been exaggerated (statements 1, 3, 8 and 9). Most of the students in class 1 indicate a low degree of agreement to items describing a personal involvement (statements 5, 6, 10, 12). At the opposite, students in class 2 and 3 feel concerned about environmental issues and show a tendency to become involved and to make personal sacrifices. In table 3, we reported the percentages of negative and positive responses about environmental challenges for the three classes. The majority of the students in class 2 do not agree with the assertion that nearly all human activity is damaging to the environment (statement 17), and that animals have the same right to life as people (statement 15). The third class, express a high level of support for the animal life, even if it could save human lives in medical experiments (statements 15, 16). This third groups show the highest percentage of contributors to the notion of the natural world as something sacred that should be left in peace (statement 18). The fourth class correspond to students who answer "no opinion" for most of the 18 statements.

	Class 1 « egocentric »				Class 2 « anthropocentric »				Class 3 « ecocentric »

17		0,036				<0,001					<0,001	<0,001
18		<0,001			<0,001	<0,001						<0,001

Table 2: Repartition of the different modalities characterizing each class for different statements about environmental challenges. A modality is considered characteristic for a class when the p-value (reported above) < 0.001 (Dis= Disagree ; L. Dis. : Low Disagree ; L. Ag : Low Agree ; Ag : Agree)

Statement	Class 1 « egocentric »		Class 2 « anthropoc. »		Class 3 « ecocentric »	
	Neg.	Pos.	Neg.	Pos.	Neg.	Pos.
1. Threats to environment are not my business	63,53	32,28	93,71	4,60	95,15	3,90
2. Environmental problems make the future of the world look bleak	39,94	50,36	42,58	48,43	27,28	68,02
3. Environmental problems are exaggerated	31,21	63,41	67,02	23,79	91,42	15,47
4. Science and technology can solve all environmental problems	48,84	47,24	66,47	22,58	68,41	25,22
5. I am willing to have environmental problems solved even if this means sacrificing many goods	43,53	50,04	15,38	76,91	4,86	93,76
6. I can personally influence what happens with the environment	55,05	36,95	31,05	57,58	22,80	71,59
7. We can still find solutions to our environmental problems	25,12	71,94	5,29	91,82	4,55	91,91
8. People worry too much about environmental problems	28,38	64,97	71,01	22,90	89,51	9,42
9. Environmental problems can be solved without big changes in our way of living	39,57	56,34	56,70	37,30	65,97	29,74
10. People should care more about protection of the environment	16,65	79,96	1,49	96,73	0,65	98,61
11. It is the responsibility of the rich countries to solve the environmental problems of the world	39,97	56,55	59,52	35,26	49,81	44,35
12. I think each of us can make a significant contribution to environmental protection	24,58	72,10	2,34	96,17	1,21	98,61
13. Environmental problems should be left to the experts	36,21	59,07	81,18	10,85	96,55	4,61
14. I am optimistic about the future	27,39	62,08	27,37	53,84	40,84	47,71
15. Animals should have the same right to life as people	43,55	49,53	37,41	21,70	17,43	73,61
16. It is right to use animals in medical experiments if this can save human lives	42,15	50,4	39,39	42,48	60,69	28,50
17. Nearly all human activity is damaging to the environment	41,69	50,27	52,65	34,39	20,92	73,30
18. The natural world is sacred and should be left in peace	18,29	74,81	12,69	76,18	1,31	96,82

Table 3 : Students' responses (in percentage) about environmental challenges for the three different classes (Neg : negative ; Pos : positive)

Therefore, we suggest that the three main classes show respectively a high resonance with the three main attitudes toward environment egocentrism, anthropocentrism, ecocentrism. In table 4, we report the percentage of students in the different classes, and the proportion of girls and boys in each class.

egocentric		anthropocentric		ecocentric		No opinion	
23,8%		39,7%		30,1%		6,4%	
boys	girls	boys	girls	boys	girls	boys	girls
58,53	41,37	43,87	56,13	46,83	53,17	46,29	53,71
P value= 0.001		P value= 0.001		not significant		not significant	

Table 4: Percentage of students and boys/girls in the different classes, according to attitudes toward environment. The p value is indicated only when the gender effect is significant.

According to these results, there are more students showing anthropocentric attitudes toward environment in France than respectively ecocentric and egocentric attitudes. We can observe that there is a significant gender effect in two classes : the group reflecting an "egocentric" attitude including a majority of boys, and the group reflecting an « anthropocentric » attitude, including a majority of girls. These results are consistent with previous studies (Jenkins and Pell, 2006 ; Karpiack and Baril, 2008) revealing significant gender differences in attitudes toward the environment, particularly a lower contribution of girls in egocentrism than men. Nevertheless these studies show that women were higher in ecocentrism whereas our work does not reveal a significant gender effect in ecocentrism. We are aware of the limits of Rose questionnaire (number of questions) related to the concept of ecocentrism, anthropocentrism and egocentrism, using only a part of the scale developed by Thompson and Barton (1994) to measure these three attitudes toward environment.

More, we examined the students' responses according the three classes reflecting egocentric, anthropocentric and ecocentric attitudes in another section of Rose questionnaire. In this section, students were invited to indicate what they "want to learn about", by responding to a series of 108 diverse statements. Again, responses were made using a four-point Likert-type scale ranging, in this case, from "not interested" to "very interested", respectively scored as 1 and 4. The 108 statements include several ones related to environmental topics, as for instance, "the greenhouse effect and how it may be changed by humans » or « what can be done to ensure clean air and safe drinking water ». In table 5, we reported students' responses to the environmental–related topics according to the three main classes.

statement	*whole popul.*		*egocent.*		*anthrop.*		*ecocent.*		*chi2 test*
	neg	*pos*	*neg*	*pos*	*neg*	*pos*	*neg*	*pos*	
1. The ozone layer and how it may be affected by humans	45,9	48,9	61,1	35,0	45,6	50,2	30,8	66,4	0,000
2. The greenhouse effect and how it may be changed by humans	47,9	46,4	61,1	35,7	49,7	44,0	33,7	64,4	0,000
3. What can be done to ensure clean air and safe drinking water	31,8	63,3	47,8	47,0	30,1	66,6	17,5	80,7	0,000
4. How technology helps us to handle waste, garbage and sewage	48,7	46,4	57,1	40,6	51,1	44,3	37,4	59,9	0,000
5. How to protect endangered species of animals	31,8	63,4	34,2	62,5	23,6	73,0	7,1	92,2	0,000
6. Organic and ecological farming without use of pesticides and artificial fertilizers	54,8	37,9	65,7	29,7	57,7	34,0	40,2	55,6	0,000
7. How energy can be saved or used in a more effective way	35,1	59,3	46,7	50,1	35,9	59,0	20,7	76,8	0,000
8. New sources of energy from the sun, wind, tides, waves, etc.	36,3	57,8	45,8	47,5	38,3	57,0	23,1	74,5	0,000
9. Benefits and possible hazards of modern methods of farming	61,1	31,8	66,9	27,2	65,3	27,4	52,0	44,6	0,000
10. How people, animals, plants and the environment depend on each other	29,3	65,9	56,5	38,9	43,1	50,5	40,0	55,4	0,000

Table 5: Students' responses (in percentage) on what they want to learn about for the whole population and according to their environmental attitudes (respectively egocentrism, anthropocentrism and ecocentrism).

The results show links between students' attitudes toward environment, and their level of interest in learning about environmental topics. Particularly, ecocentric students express more concern than others in environmental topics. In another section of Rose questionnaire "my science class", students answered to what extent they agree with the statement "School science has increased my appreciation of nature". Students in the class reflecting ecocentric attitudes toward environment indicate a higher degree of agreement to this item (57,5% of positive answers) compared to those in egocentric class (36,0% of positive answers) and anthropocentric class (36,0% of positive answers). This link between school science and attitude toward environment has already been found in previous research (e.g. Karpiack and Baril, 2008), showing for instance that students who chose biology majors evidenced higher ecocentrism.

More, one section of the Rose questionnaire interrogates about out-of-school experiences. Students were invited to answer to the question « How often have you done this outside school? » by responding to a series of 61 diverse statements as “read a map to find my way”, “seen an X-ray as a part of my body”, “open a device to find out how it works” or “read my horoscope”. Again, responses were made using a four-point Likert-type scale ranging, in this case, from “never”, “rarely”, ”sometimes” to “often”, respectively scored as 1, 2, 3 and 4. In the table 6, summarizing examples of out-of-school activities according to the three different classes, we decided to preserve the poles « never » and « often ». Our data, reported in table 6, suggest that we can relate the three classes to the practise frequency of some out-of-school activities linked to nature, for instance « Collected different stones or shells », « Collected edible berries, fruits, mushrooms or plants » or « Read about nature or science in books or magazines ». Students reflecting ecocentric attitudes declare to practise more often out-of-school activities linked to nature than others.

These results are consistent with other works showing that students who feel concerned about environmental issues and showing a tendency to become involved and to make personal sacrifices, have environment view related to early life experience (e.g. Hutchison, 1998). Data in table 6, indicate as well environmentally-relevant behaviors, as for example «Sorted garbage for recycling or for appropriate disposal » or « Made compost of grass, leaves or garbage» are positively linked to ecocentric attitudes. This result is in agreement with previous research, indicating that ecocentrism is the only attitude that are predictive of environmentally friendly behavior (Thompson & Barton, 1994). In our study, the ecocentric attitude is only related to self-reported behavior and not to an observed behavior. We are aware of the limits of self-report measures of behavior, such as for instance, the desire to appear consistent with one’s expressed attitudes.

statement	***egocentric***		**anthropo.**		***ecocentric***		***chi2 test***
	never	*often*	*never*	*often*	*never*	*often*	
Tried to find the star constellations in the sky	53,1	9,5	40,6	9,2	32,7	16,3	0,000
Collected different stones or shells	23,0	14,5	8,5	19,4	7,5%	30,3	0,000

Taken herbal medecines or had alternative treatments	52,8	11,4	55,3	9,7%	46,6%	16,0	0,000

Table 6: Student's practice frequency of some out-of-school activities linked to nature according to their environmental attitudes (respectively egocentrism, anthropocentrism and ecocentrism). The responses are expressed in percentage. NS= Not significant

Finally, another section of Rose questionnaire, interrogates students about their future job. In this section, students were invited to indicate "how important are the following issues for their potential future occupation or job" by answering to a series of 26 statements, each with a 4-point Likert scale from "Not important" to "Very important". This question contains items meant to describe their priorities in different dimensions of their future work: Self-actualization, Work creatively, Leisure priorities, Care for surroundings, Power and glory, Dynamism and excitement, Fix and use hands and tools (Schreiner and Sjoberg, 2004). We found that students reflecting egocentric attitudes toward environment indicate significantly a higher degree of agreement to items related to Power and Glory as, for instance "earning lots of money", "controlling other people" or "becoming famous" than those expressing anthropocentric or ecocentric views. At the opposite, the latter answer more positively to the items related to Care for surrounding, as for instance "helping other people" classified as Benevolence in Schwartz value instrument (1994), or "Protecting the environment" classified as Universalism by Schwartz (1994) and Self-actualization items as "working with something that fits my attitudes" or "developing or improving my knowledge and abilities". We suggest that some of these results have a resonance with previous studies (Schultz & Zelezny, 1999), showing that ecocentric concerns were significantly related to universalism (positively) and power (negatively). One limitation of our study is that our work does not include the full scales of the Thompson and Barton ecocentrism-anthropocentrism measure (1994) and Schwartz's universal values scale (1994).

IMPLICATIONS

These different attitudes toward environment among the French students population reveal the importance of taking into account the diversity of these students' views in any program of environmental education. It may be important to consider for instance the ecocentric-anthropocentric distinction in the design of message to encourage environmental conserving behaviours. Indeed, students reflecting ecocentric or anthropocentric attitudes, who both support environmental issues but for different reasons, may respond to different appeals. We should encourage them to appreciate the different ways of thinking about environmental issues. According to the results, we need to consider as well the role structures other than school can play in enhancing interest in understanding of environmental problems and developing environmentally-relevant behaviours.

ACKNOWLEDGEMENTS

This project is supported by Région Rhone Alpes (Cluster 14) and the French Ministry of Education (DEPP Direction de l'Evalution, de la Prospective et de la Performance). We are grateful to our colleagues from the DEPP, to INRP (Institut National de Recherche pédagogique) for the informatics support, and to the schools, students, and teachers who made possible to collect the data.

ABSTRACT

The goal of the research was to establish to what extent project based learning, especially field study influences the quality of acquired knowledge. The research was conducted on the sample of 64 sixth-grade primary school pupils, and 70 fifth-grade primary school pupils. Separately, on the sample of 40 primary school teachers the attitudes of teachers about field study were also surveyed. The fifth-graders were divided into experimental and control groups. The experimental group practised project based learning and field work, whereas classic frontal teaching methods were used with the control group. The data collection instruments used were three tests and two questionnaires. The surveys were conducted on fifth- and sixth-grade pupils. Testing results show the increased success of the pupils included in project-based learning, especially in field study. This may be related to the increased motivation of pupils when project-based learning and field study are applied, as shown by the survey results. Therefore, the results of the research confirm the need of project-based teaching and field study.

Keywords: *learning, field study, project-based teaching, active forms of teaching, motivation*

INTRODUCTION

The concept of learning in nature or field study is wide and versatile because it comprises various forms of field study according to its concept, goals, outputs, locations, the time required etc. (Rickinson et al., 2004; Scott and Gough, 2003). Most research shows the benefits of this form of teaching. In traditional classes pupils often do not have an opportunity to learn in an amusing way and based on experience. Therefore, too often the joy of learning is fading and students learn how not to learn (Dryden and Vos, 2001.). Teachers should also try to find ways how to motivate students to learn and enjoy in it at the same time. In a modern school a pupil should be an active participant in the teaching process (Jensen, 2003.). In pupil-oriented teaching, a pupils should be more active than a teacher (or at least as active), because a class in which pupils only sit, listen and look cannot satisfy their biological, social or creative needs, their curiosity and wish to act (Matijevic, 2008.). Field based learning is one of the ways of active inclusion of pupils into a learning and teaching process and according to the research (Martin et al, 1981; Bogner, 1998; Preston and Griffiths, 2004, Dillon et al, 2006) in such a way positively influences the development of all three domains of learning through the development of social competencies, knowledge acquisition and encouraging forming positive attitudes among pupils.

Field study encourages pupils' motivation. In the research, Rickinson et al. (2004) point out positive changes in application of field study on pupils' cognitive, affective and interpersonal competencies that are developed through various forms of field study. Some of the benefits of this kind of learning are better critical thinking abilities, better test results, greater enthusiasm and motivation for learning (Ballantyne and Packer, 2002; Lieberman and Hoody, 1998; Rickinson et al., 2004). Abrahams researched how practical work influences motivation and pupil's emotional commitment. The results of the research conducted on a sample of pupils aged from 11 to 16, showed that practical work motivate pupils to learning but their emotional commitment is short-lived and that long-term use of practical work in teaching will not contribute to more pupils to choose science subjects (Abrahams, 2009.).

The research points out a number of institutional, cultural or logistic hindrances that restrict field study outdoors (e.g.. Barker et al., 2003; Comishan et al., 2004; Fisher, 2001; Ham and Sewing, 1988; Hart and Nolan, 1999; McCutcheon and Swanson, 2001; Rickinson et al., 2004; Simmons, 1998). Rickinson at al. (2004) emphasise five key obstacles of outdoor learning: fear and care for pupils' health and safety, teacher's confidence in outdoor teaching and their professionalism in teaching (e.g. absence of pre-in-service teacher's training); unadapted curriculum (e.g. curriculum does not leave enough time for organising field study, the teaching method that do not prepare pupils for standardised tests etc.); lack of time, means and support (e.g. too much additional work for teachers, shortage of financial resources, transport and accommodation problems); support of wider educational system and supporting structures (e.g. size of class, field study limitations, emphasis on programme basis).

Rickinson points out that some of these hindrances might be solved by organising outdoor classrooms in a school yard and school surroundings because in such a way the costs are reduced as well as the time required for organising that kind of teaching (Rickinson et al., 2004.). Dyment research (2005.) showed that green schools grounds can reduce the hindrances of outdoor learning. Within the framework of formal curriculum, the examples from literature suggest that there are numerous subjects that might be taught outdoors in the school surroundings (Adams, 1990; Bell, 2001; Centar za Ecoliteracy, 1999; Cronin-Jones, 2000; Engel, 1991; Gamson Danks, 2000; Grant and Littlejohn, 2001; Hansen-Moller and Taylor, 1991; Lieberman and Hoody, 1998; Malone and Tranter, 2003; Olwig, 1991; Rhydden-Evans, 1993; Thomson and Arlidge, 2000). The authors who investigated the possibilities of field study in school surroundings agree with the fact that the learning context is changed, as well as pupils' motivation, pupils more easily make concepts and connect knowledge. Pupils have more opportunities to notice interconnectivity between education, their homes and everyday life.

GOAL OF RESEARCH

The goal of research was to establish to which extent the primary school students are included in field study, what their experiences with field study and project-based learning are as well as their attitudes about field study.

Another question was to establish how much active inclusion of pupils into a teaching process through projects and field study influences the quality of acquired knowledge and pupils' motivation for learning.

MATERIALS AND METHODS

The research was conducted during the school year 2006/2007on 68 six-grade pupils aged 12 – 13. The pupils were divided into an experimental (E) and a control group (C) with the pupils of two classes (47) in the experimental group, and the pupils of the third class (21) in the control group. At the beginning of the research all the pupils were tested (an initial test before the beginning of teaching the specific subject matter - test I) due to the need for establishing the initial state and comparison of students in groups E and C.

The experiment was conducted in the period in which Deciduous woods, a teaching unit divided into 7 smaller units was taught, during which the experimental group made two independent projects which included independent work outside school and at home.

In the first project (Project 1 – Visit to a deciduous forest) the pupils were divided into groups of 5. Each pupil got the instructions for conducting the project and its presentation. Their task was to visit a nearby forest and observe everything around them. They should use the material collected to make a poster with the topic Deciduous forest in 12 days. Upon the end of the project it had to be presented to the other pupils in their class. Each group got three marks that comprised creativity, usage of additional literature and presentations. In this way, we wanted to encourage the pupils to learn how to observe the world and nature around themselves. Competitive spirit as well as mutual cooperation was also supposed to be encouraged.

In the second project (Project 2 – Essay on the topic of protected animal species in a deciduous forest or an essay on the topic of medicinal plants in a deciduous forest) the pupils were divided into pairs. Each pupil was given instructions for conducting the project in the period of 14 days and the detailed instructions how to write an essay. The task was to find at least 3 selected species in literature learn about them in details. This project was intended to encourage the pupils to use additional literature, use the Internet as an educational means and show them how to write professional articles in the field of biology. Each pair got a collective mark which included the mark for creativity, text processing and a presentation. Teaching in class, not dependent on the projects, was adjusted to pupils. Pupils were put in the centre of attention, a teacher was only a leader of various active ways of learning. The pupils were taught how to work on the text, how to differentiate between what is more and less important and present the text in the form of bullet points convenient for learning. There were 3 different types of work on the text: make conclusions about the answer to the question asked in the worksheet and presentation of the answer to the rest of the class, summarise the text by extracting the bullet points, differentiate between the more and less important by using the two-coloured texts when making conclusions about the forest layers and mapping the knowledge and make a concept map and presentation to the rest of the class. Except for working on the text, the teaching unit called The tree layer in a deciduous forest was presented on the pupils' posters from the first project. The poster materials were used for teaching the pupils about the trees that can be found in a deciduous forest. The topics regarding the animal world, protection and exploitation of woods are also taught by means of mind maps, which proved as an efficient and simple solution. Revision was done through games.

Three tests were used as instruments for collecting data. At the beginning of the research all the pupils were tested for establishing the initial state and comparison of the pupils from E and C groups (initial test before the beginning of teaching of the specific subject matter – test I). After the first project had been finished, the pupils took test II. The test contained the questions from the course book and no questions connected with the project. We wanted to check if there was the difference in knowledge acquisition among the pupils depending on the fact if they worked on the project or they only attended regular classes at school. After the end of the second project the pupils took the second test which comprised the subject matter of the teaching unit Deciduous forest. The questions were exclusively connected to the subject matter from pupils' handbooks.After the experiment had been completed, the sixth-graders who participated in the research were surveyed with the purpose of collecting data on their own experience of teaching methods and application of projects.

The fifth-grade pupils did not participate in the described experiment, but they were polled in order to examine their attitudes towards project based learning and school in nature, based on the experiences during their education, since the fourth-grade curriculum prescribes a week of school in nature.

The results were analysed by the programmes EXCEL 2007, STATISTICA 8. Statistical significance was established based on ANOVA analysis, and for the presentation of interrelationship of results and variable connectivity measures, the Pearson's correlation coefficient. By linear regression model the trends of test results (success) were established. According to the previously published results of the research (Luksa et al, 2009) it was established that although logarithmic regression form explains pupils' results better, it is better to use a linear model to present the total test results success, since it still shows satisfactory reliability, but also diminishes the significance of rare successful individual test results.

RESULTS

By conducting initial testing (I. Test) of the pupils in both experimental (E) and control (C) groups (Figure 1.), statistical difference of results was not established, by which the balance between E and C groups in previous knowledge on deciduous trees was confirmed, which enables further comparison of the results during the research. Significant difference between individual results of the E and C groups during testing was not established, which points to the homogeneity of the pupils' results.

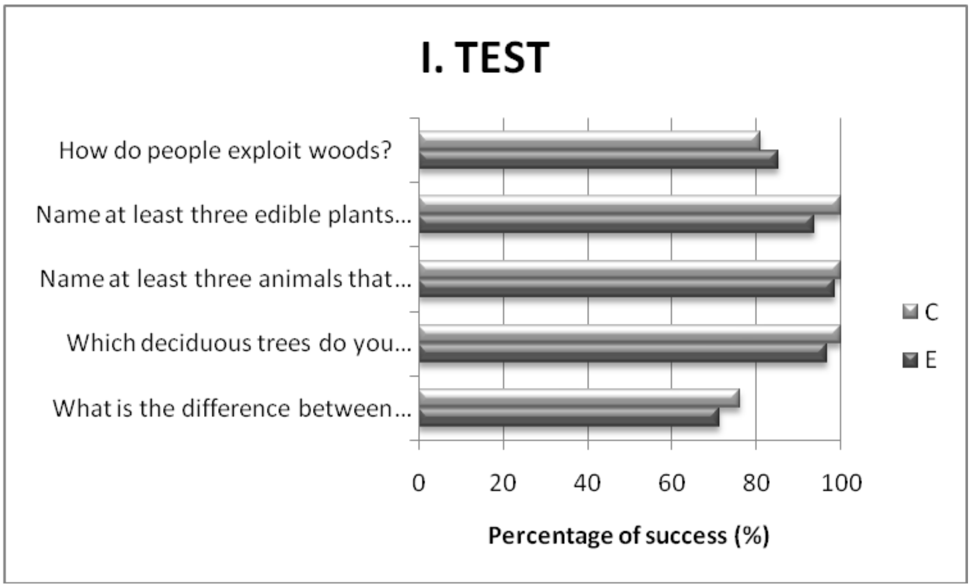

Figure 1. Results of the initial test of the experimental (E) and control(C) group

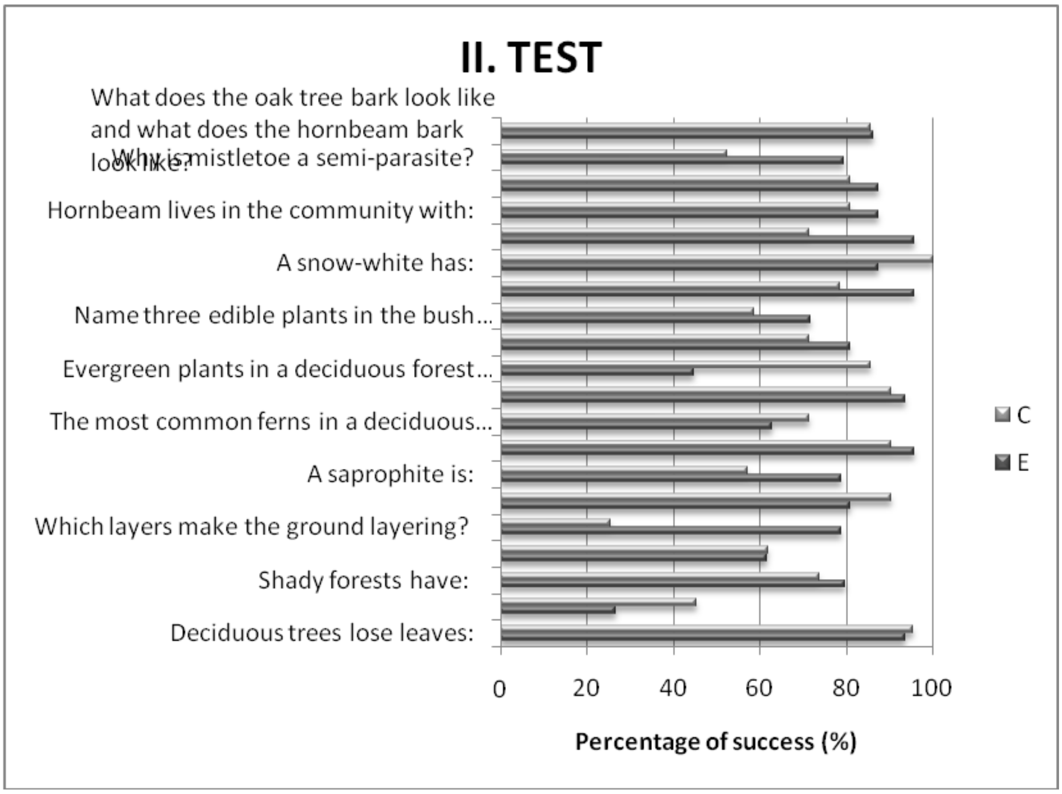

Figure 2. Results of Test II of the experimental (E) and control (C) group of pupils, before which the group E had worked on Project 1: Visit to a deciduous forest

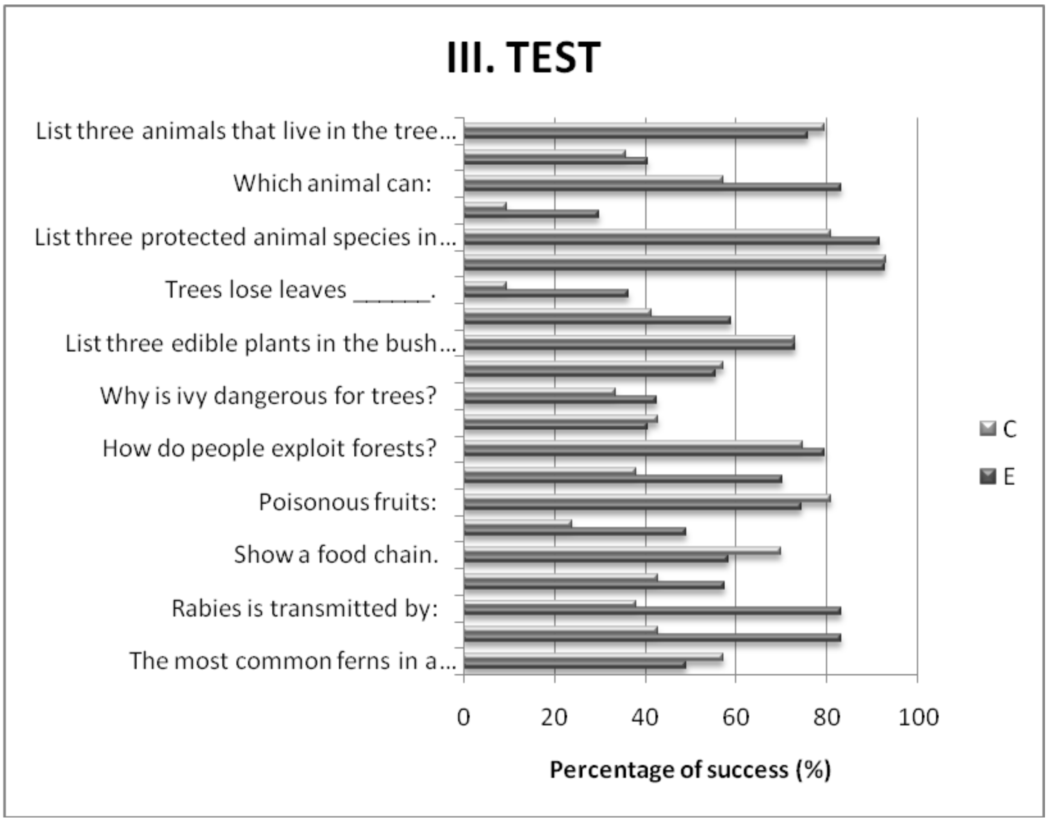

Figure 3. Results of test III of the experimental (E) and control (C) groups, before which the group E had worked on Project 2: Essay on the topic of Protected animal species in a deciduous forest or an essay on the topic of Medicinal plants in a deciduous forest

In Test II the results of group E were 65% better compared to group C (Figure 2). All the questions were connected to the contents which the pupils from group A additionally met during working on the project. In Test III the results of group E were 67% better compared to group C (Figure 3). Having analysed the questions that repeat in Tests II and III (Figure 4) the pupils included in the project work solved the test results were 15 to 27 % better than the results of the pupils from the control group. The answers to the question connected to the explanation why trees lose leaves, were done better in Test II by the C group pupils, but in Test III their success was 36% lower which indicates to more permanent knowledge of the E group pupils.

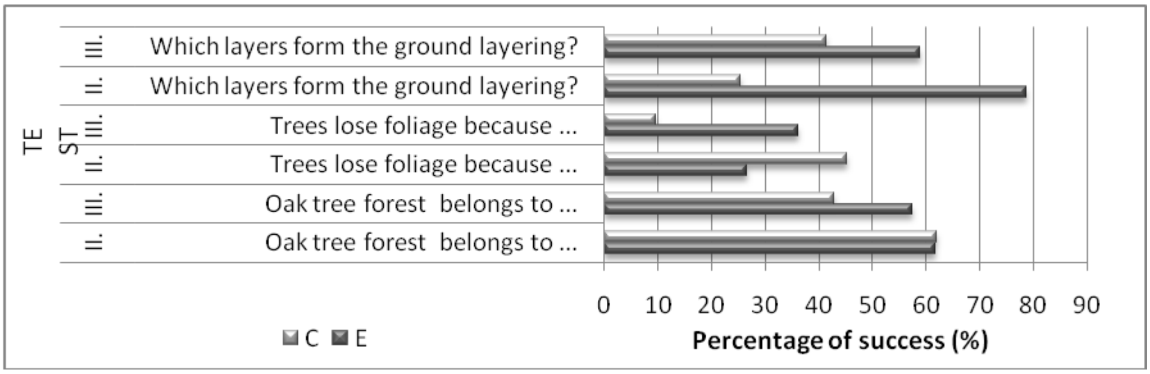

Figure 4. Results of solving the questions that repeat in Tests II and III of the experimental (E) and control (C) groups

By the analysis of mean value results for E and C groups, as well as the variability of the obtained results (Figure 5), in spite of lower variability of results for the C group, mean values for the E group are 6.8% (II. Test: E = 74,5±13,85; C = 67,7±13,44) and 8,5% (III. Test: E = 65,9±21,61; C = 57,4±21,13) higher compared to the C group = success in solving tests during the research decreases significantly in group C whereas group E shows better results. These conclusions are confirmed by significant differences between the E and C testing groups (II. Test: F(3,99) = 6,69; p<0,012; III. Test: F(3,99) = 4,63; p<0,035).

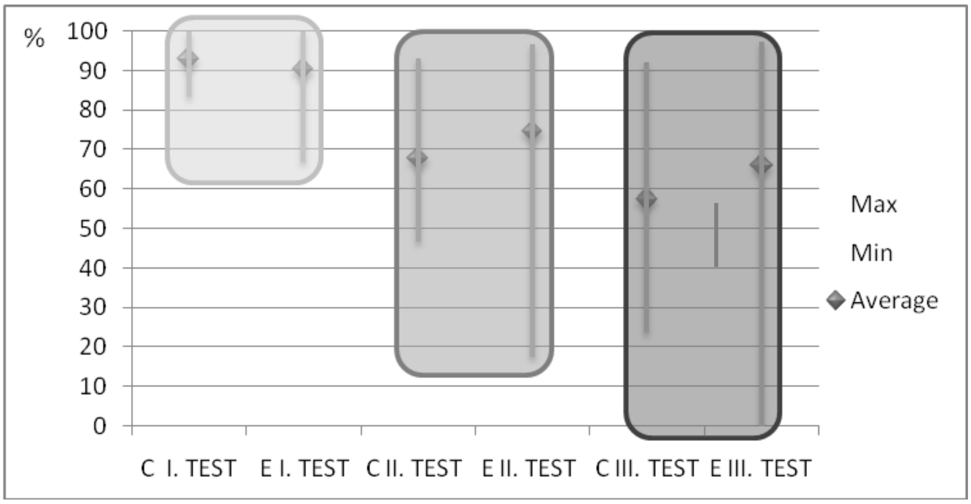

Figure 5. Range of results and mean values of pupils' results of three tests conducted in the research

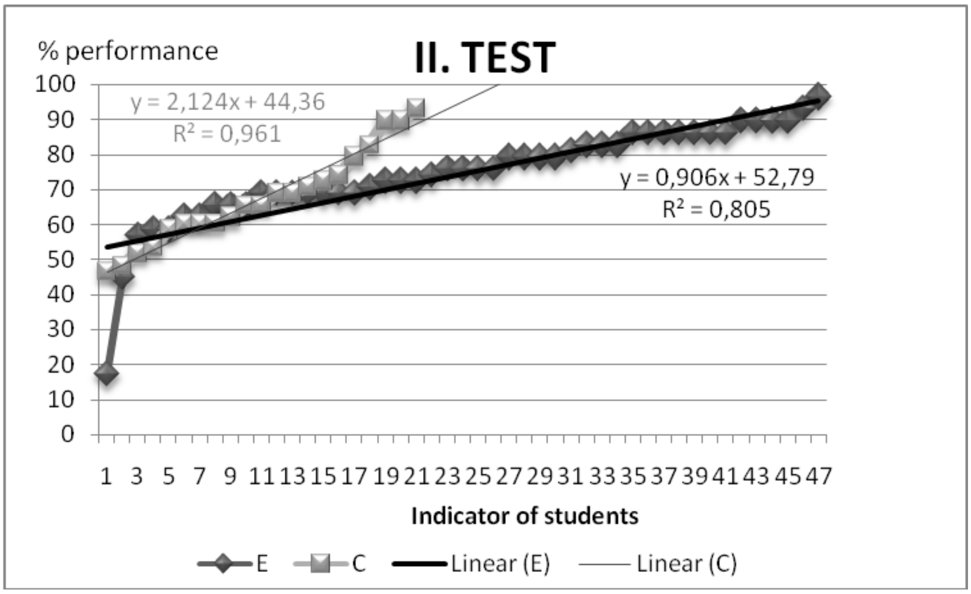

Figure 6. Linear regression of test result percentage for test II.

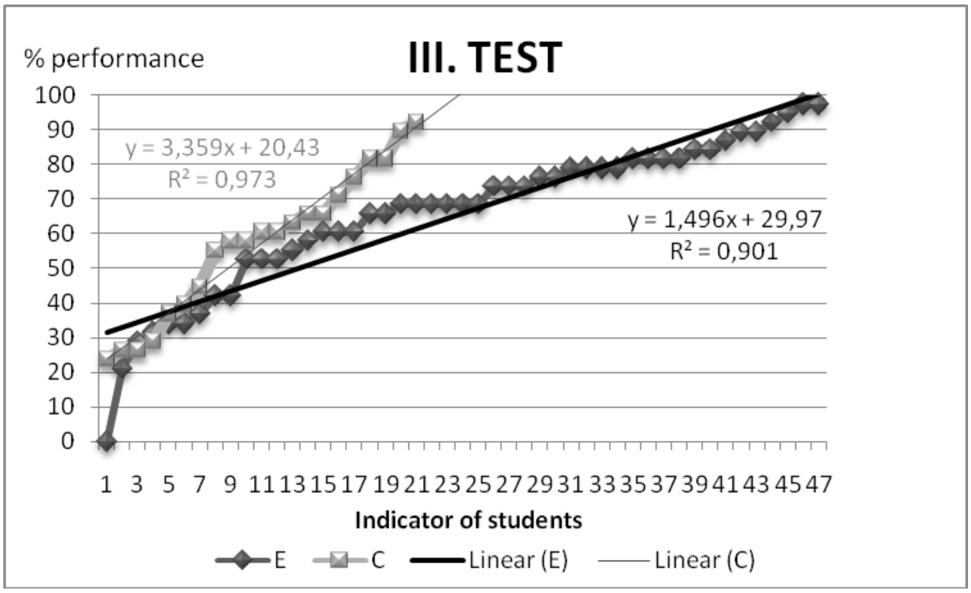

Figure 7. Linear regression of test result percentage for test III.

The data obtained by the research show that percentage of successful learning by using project methods increases and that the growth is more significant after the first project (II. Test) with more moderate slope of the regression line, whereas after the second project (III. Test) it is slower and more irregular with more significant regression line slope (Figure 6). The control group follows the results of the experimental group, which points to lower variability and better average success in solving test II (Figure 5). A smaller segment on the y axis indicates lower success in solving exercises, and the horizontal regression line shows higher balance in solving exercises, whereas the horizontality of regression line points to greater homogeneity of success among the examined pupils. The lowest value of the segment on y axis was noted among the pupils of the C group in Test III (Figure 7), which points to exceptionally bad results of group C in the last test (Figures 5 and 7).

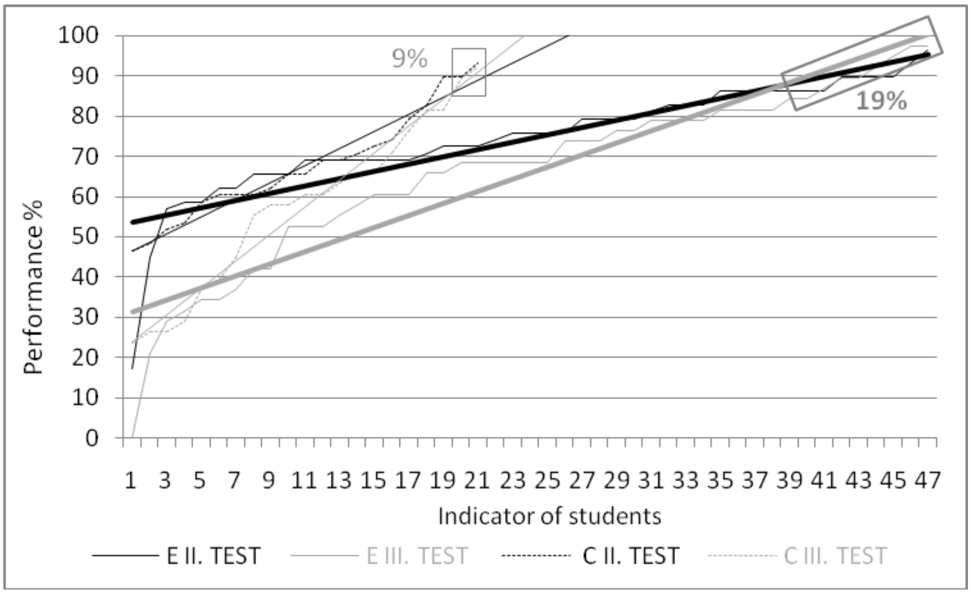

Figure 8. Differences in solving success of tests II. and III. in groups E and C

By final testing it was established that the most successful pupils (19%) achieve better results if the work includes the research of additional resources like during the implementation of the second project (Figure 8).

STUDENT'S QUESTIONNAIRE

Analysis of the questionnaire of the sixth-graders after the completion of the experiment showed that almost all pupils liked project work (from 87 to 91%) but field study is statistically better accepted ($F_{(2,66)}$= 3,68; p<0,01) compared to project work in a classroom. Satisfaction in project based learning highly correlates to the results achieved during testing of the pupils in group E (r = 0,99; r^2 = 0,98). As the main reason for accepting the project based form of learning 61% of pupils mention better interest, working in groups, going out to nature (54%) and better understanding among pupils (in questionnaires for fifth-graders who did not participate in the experiment related to the research (but they participated in in school in nature as part of prescribed fourth-year curriculum), pupils also say that they like when they participate in project work projektnoj nastavi i terenskoj nastavi., and a greater number of pupils says that they like field study). Statements of sixth- and fifth-grade pupils are in a significantly positive interrelationship (r = 0,99). Pupils quote similar reasons why they like school in nature: it is more interesting, they communicate more and better with other pupils, communication with teachers is better, they work more in groups or pairs, better atmosphere.

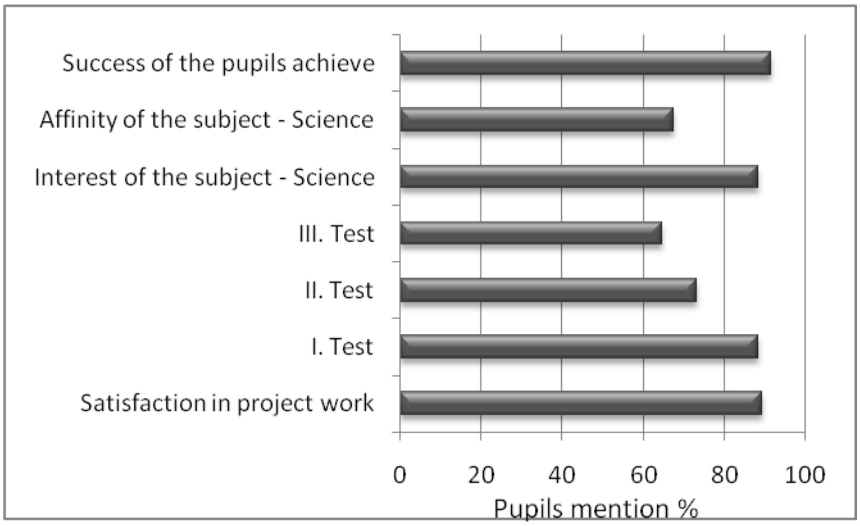

Figure 9. Connectivity of interest and learning success of the E group pupils

Satisfaction in project work, interest and affinity of the subject - Science, and success the pupils achieve during regular classes and during the research (Figure 9) show positive connectivity ($r = 0{,}68$; $r^2 = 0{,}46$).

Even 91% of the pupils think that they learned more by working on projects and during field study and therefore they want to practise it in the future, whereas 9% of pupils do not accept project tasks and thinks that that kind of teaching do not contribute to better learning results.

Out of all teaching methods used in class. pupils gave the highest mark to group work. To the question when they learn more, 71% of pupils answered that they learned the most when they combine teacher's lectures and individual work, 23 % of them said when they worked individually, and only 6 % during a teacher's lectures. This information shows the importance of systematisation of active forms of teaching. 65% of pupils assessed project approach to work with an excellent mark, 15 % as very good, 18 % good and 2 % insufficient.

DISCUSSION AND CONCLUSION

Pupils were more successful in the first project which included field study, and evaluated it as more amusing. The second project which included more theoretical work using the sources of data on deciduous forests, the majority of students evaluated as less interesting. The students were more successful in the first project, which was also assessed as amusing. The second project was experienced by most of the pupils as less interesting. Hodson (1996.) points out that learning biology is more successful with first-hand evidence and from field-study experience. The data that are not obtained directly often leave pupils not enough informed (Greaves et al, 1993). Learning success falls among the pupils in group C, as well as their motivation. The pupils from group E showed progress in learning success. On the other hand, the pupils from group C lose interest for a topic when the class ends. In spite of that, it is also shown that together with field study, the pupils who achieve best test results should be offered additional sources of knowledge as well. Cluster analysis of success in solving tests shows better success of solving tests after the first project (Luksa et al, 2009.), which points to better motivation that might have influenced better learning results, because larger number of pupils in the survey assess the first project as more interesting due to the field study. Rickinson et al. (2004) in their studies also emphasise positive changes that have arisen out of the application of field study in teaching which among others, contribute to better test results (Ballantyne and Packer, 2002; Lieberman and Hoody, 1998; Rickinson et al., 2004).

When evaluating teaching methods, all examined pupils assessed cooperative learning as the best, then group and pair work. We can suppose that the lack of this kind of work in group C might have caused fall of motivation and their lower results. The analysis of the survey of both graders shows that pupils accept project work but they prefer field study, which is in line with the results of other authors' research about field study as a way of active inclusion of pupils into a teaching process and in such a way a positive influence on the development of social competencies, acquisition of knowledge and development of pupils' attitudes (Martin et al, 1981; Bogner, 1998; Preston and Griffiths, 2004, Dillon et al, 2006). The results show that both the pupils who participated in the experiment and other surveyed pupils state similar reasons why they like field study – fun, entertainment, group work, going out to nature, better communication and understanding among pupils, better communication with teachers, better atmosphere. All the mentioned reasons support the statement that field study is essential for pupils' motivation (Ballantyne and Packer, 2002; Lieberman and Hoody, 1998; Rickinson et al.,2004). Pupils also think that through field study they learn more successfully, and only 9% of the pupils do not agree with that statement. It is especially interesting that they mentioned, as the best way of learning, the combination of teacher's lectures and individual work which indicates the importance of systematisation of active teaching methods.

Although field study is not represented enough in teaching, the fact that the awareness of the importance and need of organising field study more often is encouraging, and the results of this research show that use of project based teaching, primarily accompanied by field study, may be an ideal solution for pupils' motivation, and as a result of that, better success in learning.

NEED FOR NOVICE SCIENCE TEACHERS' CONTINUAL PROFESSIONAL DEVELOPMENT

Birgitte Lund Nielsen

Center for Science Education, Aarhus University

bln@cse.au.dk

ABSTRACT

Results from a survey of a local cohort of newly qualified Danish science teachers before they began their first jobs in primary and lower secondary schools (n=110) show a need for continual *Professional Development* (PD). The results highlight two main areas of concern based on the newly qualified teachers´ reflections on scenarios of science teaching, their considerations about themselves as future science teachers etc.

These include a tendency for the teachers to limit *Inquiry Based Science Teaching* to *activity driven science*, which suggests there is a need both in in-service PD and pre-service training to nudge the teachers away from science activities for motivation alone and towards students' learning and how they may become scientifically 'literate'. Furthermore the results suggest that beliefs held by the teachers about their own subject matter knowledge may, for a large subgroup in the cohort, affect how the teachers' approach the physics content when teaching primary Science & Technology (grade 1-6 in the Danish schools). Beside this the cohort can be divided into subgroups with great variation in strengths and weaknesses when it comes to being agents in contemporary science teaching. This description of subgroups may be an analytical tool when planning school based PD.

INTRODUCTION

Crossing the border between pre-service teacher training and the first position as a qualified science teacher is a critical phase, which has been the subject of wide ranging research and developmental work. This has often focused on particular issues raised by the novice teachers and has examined what induction features could address these demands (Britton, Paine, Pimm & Raizen, 2003*;* Davis, Petish & Smithey, 2006).

But induction is not the only issue when discussing the need for continual Professional Development (PD) after pre-service training. There seems to be a need for sustained learning opportunities that span the whole teaching career (Feinam-Nemser, 2001), not least in the complex field of science teaching.

For many years it has been known that children's early experiences with science in primary and lower secondary schools are crucial in relation to creating scientifically literate citizens, and that teachers play a significant role in determining students' attitudes to school science and their subject choices (Osborne, Simon & Collins, 2003). It is widely agreed that teachers are among the most significant factors in educational reforms of all kinds (Borko, 2004), and maybe the single most important factor in relation to the quality of science education (Osborne et al., 2003). What students learn is directly related to how teachers teach and if schools are expected to produce more powerful learning on the part of students, teachers must be offered more powerful learning opportunities (Feinam-Nemser, 2001). Research in this area suggests that science teachers, novices as well as experienced teachers, seem to need tools to critically examine, reflect on and discuss their own and others´ practice in order to continuously enhance their competence in teaching the highly complex content of science. But Professional Development (PD) opportunities are often sporadic and isolated, even though there is a growing consensus that PD activities yield the best results when they are long-term, school based, collaborative and focused on student learning (Hiebert et al 2002; Shulman & Shulman, 2004; Roth 2007; Anderson, 2007).

In Denmark there is a relatively new research project, which is trying to redress the way of framing PD and which aims to take into account the principals set out above. The Danish science teachers are involved in collaborative learning groups and given the opportunity to consider, evaluate and reflect upon their own practice through the use of video and other artifacts of practice. To qualify and evaluate the work in these learning groups and to be able to back a claim that specified PD activities in these groups are meeting some vital challenges, there is a need to know in more detail *what* are the vital challenges in Denmark? What are the demands of a local Danish cohort of science teachers in terms of continual professional development after pre-service training? The research presented in this paper is a background study created with the aim of producing such a diagnosis.

RESEARCH QUESTIONS

- *What are the professional starting points for teaching science for a cohort of new Danish science teachers?*
- *What might help or hinder the new teachers in being agents in contemporary science teaching and what seems to be the demand for continual professional development?*

THEORETICAL BACKGROUND

The term: *Professional starting point* in this study includes the teachers' backgrounds in science in and before teacher training, the way the new teachers feel prepared to teach various sub content in science and basic elements of knowledge and beliefs about science teaching as expressed in their reflections on their own school practice experiences and a range of science teaching scenarios. The aim is to characterize the cohort, examine possible variation within the cohort and to compare these findings with the contemporary visions and recommendations about science teaching based on research and recent policy papers.

TEACHERS' KNOWLEDGE, BELIEFS & ORIENTATIONS

The work of science teachers is complex, highly dynamic and requires lots of decision making, as well as knowledge. At the same time personal beliefs, practices and values impact in a broad range of ways (Wallace & Loughran, 2003) on how any one individual teaches. Pedagogical Content Knowledge (PCK) has for the last 25 years been used as a construct to indentify teachers' professional knowledge (and beliefs), i.e. for science teachers that would be the best way of teaching specific science content and concepts to particular groups of students (Shulman, 1986; 1987; Abell 2007; 2008). PCK is highly content and context dependant and to "measure" a teacher's PCK is not easy, if at all possible (Baxter & Lederman, 1999). The term professional starting point includes basic elements of science teacher beliefs with the aim of characterizing a cohort, *not* to understand in depth the PCK of a single or a few teachers in reference to a specific science area, like in the ongoing PCK research program (e.g. Abell, 2008, et al. in theme number of International Journal of Science Education, Vol.30). But along with the fundamental understanding, that learning to teach involves integrating/transforming different kind of knowledge: subject matter knowledge, pedagogical knowledge and knowledge of school context (Feinam-Nemser, 2001), certain PCK sub-elements, prove useful in the analysis and discussion.

Research has shown that teachers' beliefs are an important element when they make decisions in their practice; teachers may have similar knowledge but teach in very different ways. Existing knowledge and beliefs are often tacit, but still critical in shaping what teachers learn when involved in PD (Pajares, 1992; Friedrichsen & Dana, 2003).

When looking into science teachers' practices various *orientations* (knowledge and beliefs about the purposes and goals of teaching science) have been used in research, e.g. nine different science teaching orientations: process, activity-driven, discovery, project based etc. (Magnusson et. al, 1999). But later research has shown that prospective and practicing teachers often show a mix of orientations when exposed to a range of science teaching scenarios in a card-sorting task, which suggests that teachers can hold multiple teaching orientations (Friedrichsen & Dana, 2003). In a research review it is concluded that teachers' orientations towards teaching science are a messy construct, context specific and not coherent (Abell, 2007) and as Friedrichsen and Dana warn, this makes it difficult to build up a precise profile of an individual teacher from reflections on scenarios from science teaching. But the tool of using scenarios can still be useful to help teachers articulate knowledge and beliefs (Friedrichsen & Dana, 2003) and may therefore be a useful tool for looking into what characterises *a cohort of teachers*, for example the distinction between a *student centred conception* of science teaching versus *a teacher centred conception* and an *activity driven orientation* versus *a transmission orientation* (Abell & McDonald, 2006; Abell, 2007). When looking into teachers' views on students' inquiry a continuum of approaches have been seen in research, where the extremes can be labelled an "old orientation" versus a "new orientation" (Anderson, 2007). The one extreme is a transmission orientation, a t*eacher centred conception with teacher as dispenser of knowledge and students as passive receivers working with teacher specified activities*. The "new orientation" is a *student centred conception,* seeing *teacher as coach and facilitator and student as a self-directed learner* (Anderson, 2007). A tri-partition is also used in the field of science education research; what Anderson calls the old orientation can also be labelled *a traditionalist teacher,* the other two orientations being: *the process oriented teacher* (who focuses on scientific methods and experimental knowledge) and the *constructivist teacher* (who helps students construct knowledge)(Tsai, 2002).

CONTEMPORARY SCIENCE TEACHING

When using the term contemporary science teaching in this study it is with reference to research in the field of science education as well as recent important policy papers. This is in line with recommendations for research to synthesize what is known (about teacher education and professional development) from research and the organizational context at the policy level (Grossman & McDonald, 2008). The recommendation of an EU initiated expert group in broad terms signals a move away from school science-teaching pedagogy that advocates mainly a deductive approach and suggests Inquiry Based Science Education (IBSE) (Rocard, 2008) instead. The group found evidence connecting the way science is being taught and young peoples' attitudes towards science: traditional science education can stifle young children's natural interest in science and have a negative impact on their attitude towards learning science (Rocard, 2008). This is supported by research showing that students desire more opportunities for practical work in science classes, extended investigations that encourage student autonomy and discussions (Osborne et al., 2003).

Inquiry has been a prominent theme in science curriculum improvements since the post-Sputnik era (Anderson, 2007), so what is new about the IBSE? Many current notions still reveal a preconceived idea, which limits inquiry in the science classroom to "hands on" and/or student "originated activity", but building on Bybee, 2006 IBSE is not a single teaching strategy. Essential features of inquiry in the science classroom according to Bybee are that:

- the learner engages in scientifically oriented questions
- the learner prioritizes evidence in responding to questions

- the learner formulates explanations from evidence
- the learner connects explanations to scientific knowledge
- the learner communicates and justifies explanations.

These points highlight that inquiry should not be limited to learners' hands-on experiences based on self-formulated questions and problems, but that the learners' explanations and communication should also be taken into consideration. Grounded in a socio-cognitive perspective on science learning such an *integrated approach to inquiry* (Abell & McDonald, 2006) is important, this means as well as "hands-on" there should be "heads-on" - that is learners should be given the chance to talk science as well as do science. In such a view on IBSE the *process oriented* approach suggested by Tsai seems to have merged with the *constructivist* approach.

IBSE as an important aspect of contemporary science teaching is also emphasized by another recent European policy paper: *Science education in Europe - critical reflections* (Osborne & Dillon, 2008). This paper claims that school science is still dominated by transmission, with opportunities for students' argumentation being rare and few chances for students to use the language of science, to discuss and to think critically. Additionally the argument is that the focus on foundational knowledge of sciences like biology, chemistry and physics is not enough when the vision is *science for all,* not just for future scientists. The nature of science is an important element and there is furthermore a need to consider how teachers are prepared for teaching integrated science (Osborne & Dillon, 2008), e.g. Socio Scientific Issues (SSI).

Research shows, that it is not enough to discuss how to challenge the traditionalist transmission orientation to teaching science, as other studies have highlighted the opposite problem: a purely activity-driven orientation; students spending a lot of time doing science, but little time thinking, talking, posing questions, or constructing explanations – all with the goal of making science fun, while forgetting the goal of students achieving understanding (Abell & McDonald, 2006). A study that aimed to profile a local cohort of US pre-service primary science teachers enrolled in a method course shows a tendency towards focusing on making science interesting, enjoyable and fun through activities, without mentioning what was learned (Abell et al., 1998). This study additionally describes a widely held lack of confidence with science teaching based on these novice primary science teachers' negative experiences as learners and a tendency towards judgmental frames, which can make it difficult to see the complexity in the classroom. There was also a tendency to rely on buzz-words (exact text-book phrasing)(Abell et al., 1998). From such studies it seems that it is important to be aware of the activity-driven extreme when looking at primary science teachers, while the traditionalist view maybe more common among secondary science teachers as mentioned by Osborne et al. (above) and as noted in the study by Tsai, 2001.

SCIENCE TEACHERS IN DENMARK

There has not been much research on the characteristics of Danish pre-service science teachers. In Denmark there is a division between training to become a primary or lower secondary teacher, which takes place at a University Colleges (UC) (this cohort), and training to be an upper secondary teacher at a university. The UC has in the public debate been criticized for valuing the pedagogical content over subject matter, while concern is of an opposite character when it comes to education of teachers for upper secondary (Danish gymnasium): solid subject matter background, but maybe not so much pedagogy. Students entering teacher education at a UC have been referred to as having a humanistic profile and concern has been raised about graduation of too few new teachers with a science specialisation and that some of those who have graduated having too little background in science subject matter. A recent reform aimed to strengthen science lead to raised admission requirements and ETCS for science, with the immediate result that fewer students took science specialisations. So there is definitely a need for new reforms. The cohort in this study entered *before* the reform outlined above and can be seen to represent a typical cohort of the science teachers out in the school system at the moment. When searching for a diagnosis of – a reason for - the demand for continual PD in a Danish setting in this study it is with this local Danish context in mind, as well as with reference to the more general discussions in contemporary science teaching outlined earlier.

METHOD

Sample

Informants are novice science teachers who graduated in June 2009 from VIAUC Teacher Education in Aarhus (n=110). This is the full local cohort who specialized in the four science subjects offered in training for Danish primary and lower secondary teachers: Biology, Physics & Chemistry, Geography and Science & Technology (the three first subjects are taught in lower secondary, grade 7-9, while the last, Science & Technology, is primary science, grade 1-6). The response rate was 79%, calculated on the background of the 87 informants who completed the full questionnaire. No replies are distributed over all four specialisations.

Data collection

Data was sampled through a semi-structured web-based questionnaire, containing Likert scaled questions revealing background information, but with central questions seeking additional open ended, word based answers due to the exploratory character of the part of the study focused on the novice teacher reflections (Cohen, Manion & Morrison, 2008). All Likert scales were 5 point scales.

The questionnaire was administered at the end of training, but before the informants started work as teachers. Data include the teachers' answers about their background in science subjects, how well they felt prepared in relation to various issues of science teaching (partly based on Darling-Hammond, 2000, p.93-94), their considerations about themselves as future science teachers in various subject matter areas, reflections on what they have learned from school practice and furthermore their reflections on a range of science teaching scenarios (Friederichsen & Dana, 2003).

These scenarios were used in interviews by Friedrichsen & Dana, and are also used in interviews in the learning group part of the full research project referred to here; the open ended approach in the questionnaire is a pragmatic choice: "as close as possible" to a qualitative methodology, but still covering a broader group of informants (the aim of profiling a cohort). The questionnaire was piloted and refined before final data collection

ANALYSIS

Analysis of Likert scaled answers included frequency analysis and cross tabulations.

Open answers were approached as qualitative data with methods from content analysis (Cohen et al., 2007). The answers were categorised and coded using partly open coding: an inductive start of analysis grounded in the data, with the aim of avoiding codes and categories to predefine the data analysis (Cohen et al., 2007). After this first repeated reading of the open answers to seek patterns and categories, final categories and coding were framed which also referred to the theoretical background. For example the main categories when coding reflection on school practice experiences were "*student-centred*" versus "*teacher-centred*" (Abell & McDonald, 2006; Abell, 2007), but subcategories (*students' learning*, *students' interest/motivation*, *teacher planning*, *teachers' knowledge* etc.) were also included based on data. Likewise the coding of the arguments (negative or positive) about teaching a certain subject distinguished between arguments suggesting (lack of) *personal interest*, *subject specialization* or *subject matter knowledge* based on patterns seen in the first readings of data. The coding of reflections on scenarios was theory-based referring to teacher-orientations and main categories of teacher knowledge (Friederichsen & Dana, 2003; Abell & McDonald, 2006; Anderson, 2007; Abell, 2007). For example are general pedagogical phrases, science education phrases, reference to you own SMK, reference to students being active/passive, reference to students motivation and self-determination, reference to curriculum, reference to socio-scientific issue used in coding reflections.

All coding of open answers was done separately by two researchers. Inter coder reliability was more than 80% from the beginning and afterwards coding with incongruence was refined. After coding frequency analysis etc. was completed, correspondence analysis was conducted to examine possible sub groups in the cohort.

RESULTS

Only a third of the cohort started their pre-service training with a high level background in science. Based on the answers about subjects and levels gained in the science subjects at upper secondary level (the Danish gymnasium) the informants can be divided into two groups: high level background before teacher training or low level background. This is built upon *how much* science they took: A, B or C level, not on their marks. Three combinations are coded as high level: two A; one A + one B or two C; two B + one C. The result from making this rough division is 30% of the cohort had a high level background and 70% had a low level background. This is not evenly divided between teachers who have taken the various science specializations. For those who have chosen the Physics/ Chemistry specialization it is 62.5% High/37.5 % Low, Biology 24% High/76% low, Science & Technology 31% high/69% low, Geography 21% high/79% low.

There is clearly a large group of these new teachers who have only a basic background in science from secondary school, and many informants also emphasize their humanistic background in an open category, where they are asked if they are thinking about themselves as *science*-teachers (57% of replies suggested their teacher identity was attached to areas other than science). But does this mean a lack of interest in the science related area? When asked their reason for choosing a science specialisation (in a Danish context where science includes life science and earth science) 42% had always had an interest and 58% found science subjects interesting in school. Other answers in this category included job opportunities (38%) and 37% who said their interest was stimulated by what older students said at the introduction meeting at the UC.

When asked if they wanted to teach various science sub-content all the teachers of course said that they would prefer to teach their own specialization, but more teachers expressed a readiness to teach Science & Technology, Geography and Biology without having a specialization than Physics/Chemistry. When analyzing which arguments are used for not wanting to teach some given science sub-content analysis shows a partition in the cohort where arguments grounded in lack of subject matter knowledge (SMK) is expressed more often by teachers with Geography, Biology and Science & Technology specializations, than by teachers with a Physics/Chemistry specialization (comments on *all* sub-content combined). The teachers with a Physics/Chemistry specialization seem to feel more prepared to teach all sub-content, content related to life and earth science as well, and if they argue for not wanting to do it, their arguments are typically about not having subject specialization. Arguments about lack of SMK like: "*….how could I possibly teach something I do not understand at all myself",* are really only used by the teachers with the other 3 specialisations, especially when asked about teaching Physics, but also expressed in reflections about Science & Technology (primary science), in comments like: "..*I am not good in the physics part*…"

When asked about how well they felt prepared in reference to a range of pedagogical issues in science teaching (Darling-Hammond, 2000), the results show that the new teachers in general feel quite well prepared, but some interesting patterns do show in relation to activity/IBSE. When asked in general about activities the new teachers felt better prepared than when asked about science inquiries more specifically: 72% felt very well or well prepared for using approaches where students are active, but in the answers about planning and organizing students' inquiries this is 49%. This pattern is repeated when looking into science discourse: 72% feel very well or well prepared for supporting students' conceptual understanding, but when asked in more detail about discourse the feeling of being prepared falls: 55% feel well prepared for using (teacher) questions to support students learning.

From the reflections on the various scenarios *science teaching based on practical work and students' activities* seems to be an ideal for nearly all of the teachers. None of the teachers expressed a traditionalist view. The positive arguments about activity or negative arguments about passive students are seldom warranted in students' learning (or lack of learning) through the activity. A large group of the teachers typically use students' motivation; *what might be interesting/boring for students,* in their argumentation, another group typically use phrases from the field of science education such as hypothesis, *the* scientific method etc. in many of their arguments. The focus for all teachers is much more on science as a process than science as a body of knowledge and the school curriculum is nearly absent in arguing about the scenarios; the arguments are not about this particular subject matter being relevant or in the curriculum, it is for example about the approach being motivating. Reflections about "bildung" and that some themes are SSI are included by many of the new teachers.

One example of teacher reflections on a scenario where *students observe earthworms, generate questions and design an experiment*, showed that 40% of the teachers refer to students' inquiries in their argumentation about this scenario, but only a few of these (1/10) include the discursive element. A few of the teachers who refer to inquiry, explicitly mention what they call <u>the</u> scientific method when arguing. These teachers all have a Physics/Chemistry specialization and a high level background. Around 25% of the arguments about the earthworm scenario refer to active/motivated students without mentioning anything about inquiry, hypothesis, scientific method etc. These comments were made by teachers without specialisation in Physics/Chemistry.

Another example involves the reflections on a scenario where *students experiment with batteries, bulbs and wires to find possible ways to light the bulb*. In this instance 50% of the arguments explicitly refer to students being active; among these 1/5 also refer to the activity (hands on) as well as the discursive element being important. Again a few with a specialisation in Physics/Chemistry refer to *the* scientific method. 20% of the arguments about this scenario refer to a lack of SMK as a limitation, when discussing the scenario.

In the reflections on their school practice experiences during teacher training there are more teacher centred reflections than student-centred. As much as 65 % of the argumentation focuses on what they did or didn't do themselves as teachers while reflections about how to challenge student learning are far less common.

DISCUSSION AND CONCLUSIONS

The results point to at least two important issues: the newly qualified teachers' approach to physics subject matter and their approach to and beliefs about "ideal" school science.

The UC education in Denmark has been accused of valuing the pedagogical content over subject matter. The aim here is not to draw conclusions about whether the members of this cohort have sufficient background in science subject matter, because that raises the question of what is meant by 'sufficient background'? What is the ideal balance between SMK and knowledge about teaching? Research suggests that SMK is an issue for being an effective science teacher, but *not* that SMK is more important for teacher effectiveness than knowledge of how to teach (Darling-Hammond & Youngs, 2002). What you *can* say is that for a subgroup of these teachers' *beliefs about own SMK in the physics area* might very well affect the way they for example will teach primary science (while in principle the full cohort is qualified). You might try to navigate around letting your students experiment with simple electrical circuits as a primary science teacher, as illustrated by some of the teachers' comments about a scenario in which a 4th Grade science teacher encourages the students to find ways to light the bulb using batteries, bulbs and wires is: *This sounds dangerous*; *I have no subject matter background to answer the question*, *no I do not feel competent enough.* From the cohort under discussion 17% placed this scenario in the *I don't know* Likert category, when asked if it is an approach they would consider taking. But still 57% of the teachers placed the scenario in the two upper Likert scaled categories and there are several examples of balanced (IBSE) reflections like: "…*students are using their hands and you can add theory while they are working and afterwards.."* or "..*a good approach where the foundation is the student's experiments. The teacher of course has to follow up on students' experiences…"*

What might help or hinder the new teachers in being agents in contemporary science teaching? A lack of belief in their own SMK in the physics subject area may very well hinder the teachers who gave the first type of reflections; their PCK for teaching simple electrical circuits is affected by their SMK. This scenario and another referring to typically physics SMK (*a water toy rocket a classmate brought to school…identify questions and ways to explore how the rocket works…*) is where most teachers use the *I don't know* Likert category (19,3% in the latter) and where more reflections are coded with negative reference to the teachers' own SMKs, than reflections about scenarios referring to life science or earth science. The analysis points to a tendency for some teachers without a physics specialization to use value-loaded arguments: "*I know nothing about physics*", "*this is my weak side*" which points to negative experiences with working with this field. Some of this may be grounded in a variance in background in science before starting teacher training, whereas around 60% of the teachers with a Physics/Chemistry specialization have a high level background, around 25% of the teachers with the other 3 specializations have a similar background. But maybe these examples of low efficacy beliefs attached to physics go back to how these teachers themselves experienced different content fields when at school. The variation might be due to a lack of confidence based on negative experiences as learners, similar to the results from US primary science teachers (Abell et al, 1998). The conclusion on this point is likely to go beyond the theoretical and empirical background in this study.

One point for optimism in the study, when considering IBSE, is that none of the teachers seemed to identify themselves as having a traditionalist transmission orientation (Tsai, 2001; Abell & McDonald, 2006; Anderson 2007; Abell, 2007), although you have to be aware that what is seen here are the newly qualified teachers' ideals (*what they say, they want to do*), what they actually are going to do in complex and sometimes confusing classroom situations is beyond the scope of this study. Examples where teachers use a transmission approach though expressing a constructivist orientation are well-known.

The tendency to focus on activity driven science (hands on without mentioning minds on) of a large subgroup as well as the emphasis placed on *the* scientific method by a small sub-group (teachers with high level SMK and Physics/Chemistry specialization) are both important issues when discussing "*what might hinder".* In reference to the tendency to emphasize one specific scientific method a focus on the nature of science might be an important element in continual PD although these teachers have a high level of SMK, they may not be well prepared for teaching *integrated* science (Osborne & Dillon, 2008).

The conclusion is that there is a need for a balanced view on IBSE and a change of focus towards students' learning of science is clearly needed as part of PD for nearly all the members of the cohort. At the same time it is possible to divide the cohort into subgroups with *very different* backgrounds and *great variation* in strengths and weaknesses when it comes to being agents in contemporary science teaching. This does *not* mean that a division into clearly defined subgroups with clear description and limitations is easy. The qualitative data (the reflections) point to a cohort consisting of individual teachers each with their own biography and many variables that affect their approach to being a science teacher, but the vague contours of sub-groups do show, for example:

- Teachers with a specialization in Science &Technology, who have taken this subject as a part of the primary teacher training and do not necessarily intend to become a science teacher typically have a low level background in science, and an activity driven orientation appreciating activities which are motivating for primary students, and emphasizing pedagogical approaches in primary teaching in their reflections. Some express a lack of belief in their own SMK in the physics area.
- Teachers with a specialization in Biology (and fewer in Geography) who value outdoor activity highly and many combine this with sports as another specialisation in teacher training. They also note that they have always been interested in "science", but not necessarily science in the school system (*a scout approach?*).
- Teachers with a specialisation in Geography (and fewer in Biology), with an explicitly formulated humanistic profile and who do not see their teacher identity attached to being a science teacher, emphasize (global) "bildung" in their argumentation and many SSI as well. Many express a lack of belief in their own SMK in the physics area and a lack of interest in physics.
- Teachers who specialize in Physics/Chemistry and who identify themselves as science teachers, usually have a high level background and mathematics as another specialization and say that their interest developed from their own school experiences (some explicitly express that they love physics). These teachers typically gave short (word based) reflections and offered process orientation (Tsai, 2001). Some of these teachers use the expression "*the* scientific method"

It must not be concluded from these points that all teachers belong to these categories. Most members of the cohort are somewhere in between: some Geography and Science & Technology teachers have a high level science background and an interest in physics, some teachers have several specialisations and combinations of science subjects, some teachers, with Physics and Chemistry as well as other specializations, show orientation where the process and the constructivist orientation "melt together" etc. These subgroups are more like Max Webers ideal types: *idea-constructs that help put the chaos of social reality in order*. Description and a clear understanding of such subgroups (and their associated needs) may be an important "analytical tools" when planning school based PD, while it is likely that there will be great variation in background in science and orientation towards science among the teachers at one particular institution.

PERSPECTIVES

The results point to a need for continual professional development attached to the physics content and a balanced conception of IBSE as well as an awareness that there is considerable variation found when characterizing a cohort. Great variation can also be expected to be found in a science team at a given school and must be taken into consideration when planning school based PD activities.

The results furthermore suggest that there may be a need for reforms in the institutional framing of science teaching and science teacher education in Denmark.The political answer so far in Denmark has been the reforms regarding the need for a high level science background mentioned above. The consequence has been an enormous problem with recruiting students for science specializations in teacher training. This might have been predicted: nearly 70% from the cohort discussed wouldn't be allowed to take their science specializations with the current UC admission requirements. There is no easy way to solve the problems. Raising admission requirements and trying to recruit more students with a high level science background is a reasonable political step, but there might be other ways of approaching the challenges, seeing beyond what is for example the immediate understanding of what makes a good primary science teacher. Lack of belief in one's own SMK in important areas of science are shown to be a problem in this study, but continual PD might address some of these concerns and you might be able to build upon the teachers' existing competences in the general field of primary teaching.

Maybe the division into Physics/ Chemistry, Biology and Geography in lower secondary leads to divided cultures attached to science specializations, which can be followed all the way through the educational system, especially with physics which seems to have its own culture and produces few teachers who want to be resource teachers in primary and lower secondary school (and attracts few school students)? And maybe in Denmark the division between training for primary and lower secondary school in one system and training for upper secondary school in another also has to be discussed?

ABSTRACT

A multidisciplinary team carried out research to help a New Zealand university understand how to better engage their learners in the sciences, particularly in transition from secondary schools to tertiary institutes in Aotearoa New Zealand. The aim of the research is to develop a framework that will facilitate the transition of science education learners between secondary schools and tertiary institutes while maintaining key elements of engagement. A survey instrument was developed to collect quantitative evidence of engagement from four different groups: Year 12 (age 17) students and their teachers, first year university students and their lecturers. Analysis of the survey data for Year 12 students and teachers indicates that there is a significant difference between the students and teachers perceptions on some key elements of engagement in science.

Keywords: *secondary, students, teachers, engagement, science.*

INTRODUCTION

This paper will present *one part* of an Ako Aotearoa research funded project titled - *Engaging learners effectively in science, technology and engineering: the pathway from secondary to university education*. A multidisciplinary team with members from the College of Sciences, College of Education and College of Humanities and Social Sciences, conducted research to help this New Zealand university understand how to better engage their learners in first year sciences courses, particularly in transition from secondary schools to tertiary institutes in Aotearoa New Zealand. The intent is (a) develop a framework that will facilitate the transition of science education learners between secondary schools and tertiary institutes while maintaining key elements of engagement; (b) increase student retention in first year university science courses and (c) increase the number of students taking Science Technology Engineering and Mathematics (STEM)-related subjects.

BACKGROUND

Concerns about student decline in secondary science and tertiary science courses have been expressed since 2003. In 2003, Fullerton, Walker, Ainley and Hillman's reported a marked decline in the number of students enrolled in science classes of their last year of secondary schooling in Australia. A European Commission (2004) report noted the decline in recruiting, retention of students studying science, engineering and technology. Lyons (2006) in his comparison of three studies in Australia, Sweden and England of secondary school science students identified core themes linked to decline in interest and enrolments in secondary and universities. Panizzon and Westwell (2007) and Tytler (2007) also noted in their reports the decline and engagement of students in the science, technology, engineering and mathematics in Australia was not unique and is similar to many OECD countries.

A common factor in the literature on engagement appears to centre on students' attitude and the pedagogical approach taken by teachers. Hattie (2003), in his meta-analysis of student achievement, indicated that 30% of student achievement was dependent on the teachers' impact with students. He identified different aspects of quality teaching that had positive affects on students. The focus on the teachers of science was acknowledged by Tytler (2007) when he stated that changes in science education has been resisted because of science teachers' '*silent choice*' for the status quo while Osborne and Dillon (2008) draw our attention to the pedagogy of school science using the '*conduit*' metaphor – transmission of science knowledge and understanding by teachers. The New Zealand Council for Educational Research (NZCER) report (2006) to Ministry of Research, Science and Technology supports this focus on teachers. Hipkins, Roberts, Bolstead and Ferral found in their research that approximately one-third of the Year 13 (age 18) students taking sciences found their subjects were sometimes taught in a boring way.

In identifying science engagement for secondary or first year university students, the goals of science education (Years 1 – 13) in Aotearoa New Zealand need to be acknowledged as that is what the teachers are focusing on in their teaching. The goals of science education can be identified in *The New Zealand Curriculum* (Ministry of Education, 2007:28) document with the question – Why study science?

> *By studying science, students:*
> - *develop an understanding of the world, built on current scientific theories;*
> - *learn that science involves particular processes and ways of developing and organizing knowledge and that these continue to evolve;*
> - *use their current scientific knowledge and skills for problem solving and developing further knowledge;*
> - *use scientific knowledge and skills to make informed decisions about the*

communication, application, and implications of science as these relate to their own lives and cultures and to the sustainability of the environment.

The rationale for engaging with these science goals is to be commended, as they will hopefully provide Aotearoa New Zealand with scientifically literate citizens.

Therefore as fewer and fewer students enroll in science (secondary and university) and the engagement rate lowers, Massey University College of Sciences recognized the need to identify specific aspects of the teaching and learning in science that influence the engagement and retention. Identifying those impact factors associated with the teacher / lecturer would assist with reversing the trend but also guide Massey University College of Science in repositioning their science papers for the 21st century. With that in mind, the research team set about investigating the secondary and tertiary experiences of students (Figure 1) and teachers / lecturers (Figure 2) in science education.

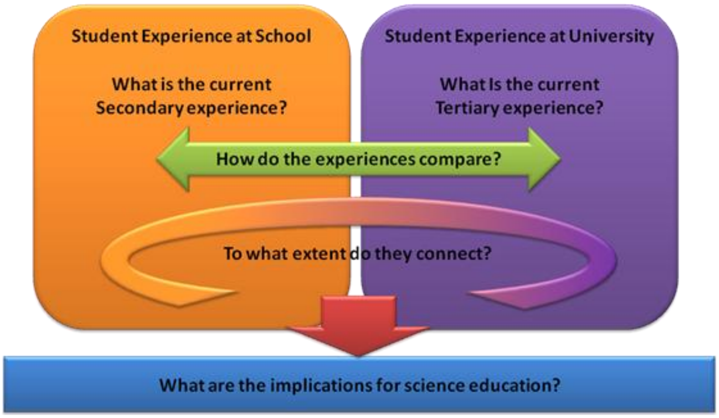

Figure 1. Comparison of student experience in secondary and tertiary science education

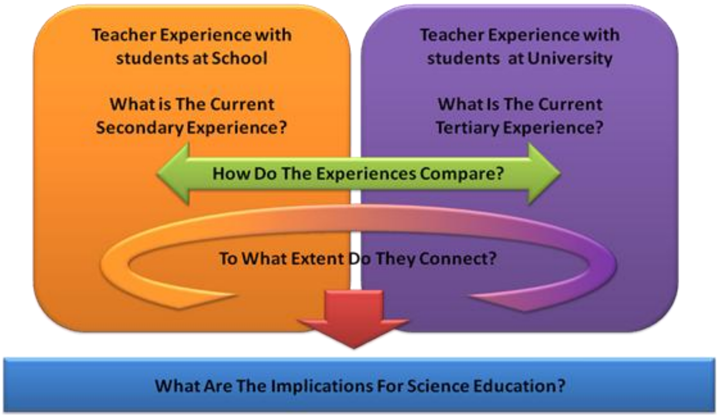

Figure 2. Comparison of teachers / lecturers experience in secondary and tertiary science education

METHODOLOGY

The research team employed a qualitative and a quantitative approach to collect the data from the four participant groups: (i) Year 12 (age 17) high school students, (ii) high school science teachers of the Year 12 students, (iii) Year 1 university students enrolled in a science course and (iv) university staff who teach or have responsibility for Year 1 science programmes. The qualitative approach used focus groups or one-to-one interviews. Similar focus questions (Table 1) were used for secondary or tertiary students and secondary teachers or lecturers. The quantitative approach used a questionnaire, which the authors will focus of this paper, for all participant groups.

Table 1. Focus questions for students and teachers

Students	Teachers
Q1. What do you like most about science?	Q1. Write three things that 'turn on' your students in your science class
Q2. When I am in science class:	Q2. When your students leave school, *what knowledge, skills and attitudes in science do you hope that they will have learnt in your classes?*
(a) I really like it when …	Q3. To achieve this goal, what do you think your current students should (i) continue, (ii) stop / do less of, (iii) start / do more of?
(b) I really don't like it when …	Q4. To achieve this goal, what do you think you or the school should (i) continue, (ii) stop / do less of, (iii) start / do more of?
(c) It would be better if …	Q5. If you could give one piece of advice to university teachers, what would it be?
Q3. What are your plans for science next year?	

Questionnaire

The questionnaire consisted of 100 questions using a five point Likert scale (1 = never, 2 = rarely, 3 = sometimes, 4 = often and 5 = always). In order to identify patterns and trends in the data, similar questions were used for the students (high school and university) and for teachers (high school and university). The design of the questionnaire was to link to literature on engagement in science (Lyons 2003, Hipkins et al 2006, Tytler 2007, Osborne and Dillon 2008 and Panizzon and Westwell, 2009), the nature of science (Ministry of Education, 2007) and the pedagogy for teaching science effectively in the classroom (Tytler 2003). Questions were identified that linked to

(a) to the broad range of affective experiences the students / teachers might encounter in a secondary or tertiary setting;
(b) to the declarative / procedural experiences the students / teachers might encounter in a secondary or tertiary setting and
(c) to effective science teaching in classrooms (Tytler, 2003 – School Innovation in Science Project).

The questions were grouped into two broad sets. One set of questions (n = 50) placed an emphasis on extrinsic factors - the teacher is directing the science engagement. An example question (Q.32) is provided from the teacher and student questionnaire. Note that the experience is being directed pedagogically from the teacher.

> Question 32:
> Teacher questionnaire - I give students the opportunity to influence the way that they are taught
> Student questionnaire - I am given the opportunity to influence the way that I am taught

The focus of the other set (n = 50) of similar questions places an emphasis on personal intrinsic factors. A teacher and student example (Q.91) is provided to demonstrate the subtle difference from the previous questions above. Student initiative is being emphasised although the stem of the question is basically the same as question 32.

Question 91:
Teacher questionnaire - Students take opportunities to influence the way that they are taught
Student questionnaire - I take opportunities to influence what topics I am taught

Due to time restrictions placed on this project the questionnaire has not been validated through normal statistical procedure.

RESULTS AND DISCUSSION

The total number of participants who completed the questionnaire in each group is identified in Table 2.

Table 2. Total number that completed the questionnaire

University students	707
University academic staff	69
Secondary school students	460
Secondary school teachers	33

Although the authors will present statistical data for the survey questions of the four groups (Table 7), the main part of this section will focus on the quantitative data of the secondary school students and teachers (one small part of the larger project). It would be equally important to discuss the data of the university students and lecturers but the submission regulations has directed the authors to focus on more detailed discussion at this time for one group. Therefore the key question for this section is: *are these two groups responding to the same questions in the same way about aspects associated with engagement in science?*

DEMOGRAPHIC DATA OF THE SECONDARY SCHOOL PARTICIPANTS

Five secondary schools participated with 460 Year 12 students and 33 Year 12 science subject teachers completing the survey (see Table 3). The student size of the schools varied from 350 (Co-ed B) to 1600 (Boys single sex).

Table 3. Number of students and teachers participating in the survey and focus groups

	Y 12 Student Survey	Y 12 Student Focus Group	Y 12 Teacher Survey	Y12 Teacher Focus Group
Boys single sex	188	3	11	1
Girls single sex	97	2	9	1
Co-ed A	95	2	7	1
Co-ed B [low decile]	27	2	2	1
Co-ed C	60	1	4	1
TOTAL	460	10 (N = 51)	33	5 (N = 39)

Tables 4, 5, and 6 identify the nationality, the gender, and number of students studying the different disciplines in Year 12 respectively.

Table 4. Nationality of students and teachers in Year 12 (N = 493)

European / Pakeha	327
Maori (indigenous)	43
Pacific Islander	14
Other	109

NB Some students ticked more than one nationality

Table 5. Gender of students and teachers in Year 12

	Female	Male
Student	199	285
Teachers	16	17

Table 6. Number of students studying different science disciplines in Year 12

Agriculture / Horticulture	32
Biology	258
Chemistry	279
Physics	265
Science (all science disciplines)	29

Factor Analysis Data

A factor analysis of the four groups of participants for the two sets of questions identified five scales for questions 1-50 and three scales for questions 51-100 (Table 7). As noted above the first fifty questions placed an emphasis on extrinsic influences while the second fifty questions looked at intrinsic influences - student initiative.

Table 7. General description of the scales derived from the extrinsic and intrinsic influences questions

General description	Total number of questions involved in the scale	Cronbach's Alpha
Extrinsic influences		
Teacher qualities	9	.841
Students are challenged to develop meaningful understandings	5	.750
Students are encouraged to engage with science ideas and evidence	6	.735
Student's individual learning preferences are catered for	4	.754
Learning technologies are exploited for their learning potentials	4	.774
Intrinsic influences		
Commitment to high performance in science	10	.884
Learning science with excitement	7	.836
Developing meaningful understandings of science	5	.789

The scales of engagement

Student engagement in secondary school science is very complex and many factors influence the active engagement (Lyons 2003, Hipkins et al 2006, Tytler 2007, Osborne and Dillon 2008 and Panizzon and Westwell, 2009). The eight scales identified in the two sets of questions (Table 7) attest to the complexity. Analysis of the eight scales and their respective questions identified four scales that direct links to Tytler's (2003) effective classroom teaching components. In addition those four scales also focus on experiences associated with science, science ideas and the nature of science. Table 8 illustrates the links between the four scales of engagement and a corresponding component for effective classroom teaching, whereas three of the scales have links to the science / the nature of science experiences.

Table 8 Scales of the engagement questionnaire, effective classroom teaching components and the science ideas and nature of science

Scales of engagement component	Effective classroom teaching component (from Tytler, 2003)	Science ideas & nature of science
• Students are challenged to develop meaningful understandings	2. Students are challenged to develop meaningful understandings	nature of science notions
• Students are encouraged to engage with science ideas and evidence	1. The learning environment encourages active engagement with ideas and evidence	science ideas
• Learning technologies are exploited for their learning potentials	8. Learning technologies are exploited for their learning potentials	
• Developing meaningful understandings of science	2. Students are challenged to develop meaningful understandings	nature of science notions

Secondary students and teachers responses

If student's experience in science were important to engagement, one would expect both the students and teachers to recognize their importance. Therefore the frequency of responses by the teachers and students should be similar. Further analysis of the questions that make up each scale identified eight questions where there was a definite difference in the response betwen teachers and students. The frequency of the response to those questions is shown in Table 9.

Table 9. Frequency of response by teachers and students

Questions	Frequencies - percent (teachers / **students in bold**)				
	never	rarely	sometimes	often	always
Q21 My lecturers relate science to things that interest me	0 / **8**	0 / **18**	25 / **32**	63 / **35**	13 / **8**
Q47 I am asked to learn how science impacts people, society and technology	0 / **12**	18 / **24**	33 / **46**	36 / **13**	12 / **5**
Q11 I am asked to learn about how science relates to contemporary issues	3 / **7**	6 / **20**	44 / **56**	41 / **15**	6 / **2**
Q35 I am expected to plan the investigations that I undertake	6 / **6**	12 / **17**	48 / **29**	21 / **38**	12 / **10**
Q45 I am expected to use data/evidence to develop a logical scientific argument	0 / **5**	6 / **13**	31 / **37**	41 / **39**	22 / **6**
Q90 I consider ethical issues surrounding science	3 / **13**	16 / **20**	39 / **48**	39 / **13**	3 / **6**
Q74 I learn how scientific ideas have developed over time	0 / **7**	18 / **21**	42 / **52**	33 / **16**	6 / **4**
Q81 I learn about how science relates to contemporary issues	3 / **7**	16 / **20**	44 / **54**	34 / **16**	3 / **3**

The eight questions have been grouped according to the scales and reflect a difference in response from the teachers and students. The first question (Q21) sits within the ‘teacher qualities’ scale while the next two (Q47 and Q11) are grouped in the ‘students are challenged to develop meaningful understandings’ scale. Q35 and Q45 belong to the ‘ students are encouraged to engage with [science] ideas and evidence’ scale with the last three (Q90, Q74 and Q81) linked to the ‘developing meaningful understandings of science’ scale.

Seventy-six (76) percent of the teachers responded often / always to Q21 while only 43 percent of students responded in that manner. This difference in response may signal the ‘boring way’ science is presented (Hipkins et al, 2006). We also see a marked difference between teachers and students in Q47 and Q11. The teachers responded 48% for often / always in Q47 whereas just 18% of the students responded that way. A similar pattern emerges with Q11 – 47% of teachers and 17% of students responded as often / always. The lack of challenging experiences to develop understanding is evident in the students’ responses.

The two questions, Q35 and Q45, also show a difference in response. In Q35 the teachers appear to acknowledge that students are lacking the experience in planning their own investigations (66% response for never / rarely / sometimes) whereas the students do believe they are involved in planning their own science investigations (77% responded sometimes / often / always). Only 6% of the teachers responded never / rarely to Q45 whereas 18% of the students responded in a similar way. Perhaps as with Q35 students’ perceptions of what they are experiencing with science ideas and evidence are not based on a foundation of science understanding and cannot recognize the experiences.

The last three questions (Q90, Q74 and Q81) are part of the scale linked to intrinsic factors around personal development of meaningful understandings. The differences in teacher - students responses for often / always range from 42% - 18% in Q90, 39% - 20% in Q74 and 37% - 19% in Q81. With these three questions, teachers believe that that are providing the students with experiences but the results suggest otherwise.

CONCLUSION AND IMPLICATIONS

This paper has attempted to identify factors that influence the engagement and experiences of secondary science students. The perceptions of student engagement and experiences from the student and teacher were elicited via a questionnaire. The questions were designed to cover some of the complex interactions occurring in the classroom between the teacher and the student. Five scales were identified from the set of questions that focused on extrinsic factors. These five scales centre on the teacher – the personal qualities, their content knowledge and their pedagogical knowledge. The other three identified scales centred on student initiative or intrinsic elements of engagement. Four of the eight scales can be aligned with four components of Tytler's effective classroom teaching as well linking to the goals of science education in New Zealand.

There are specific questions from the different scales where significant differences occur in student - teacher responses. The questions align with Tytler's (2003) School Innovation in Science project, the recommendations of Osborne and Dillon (2008) and the focus on science experiences that are in real-life contexts.

The scales derived from the questionnaire do have implications for secondary school science teachers. Their importance is centred on the engagement or we would call active learning. The notion of the student becoming an active participant in their learning is at the heart of some of the student's responses but data indicates that the same cannot be said of the teacher's response. The authors would like to suggest that the questions be used to guide the classroom science teaching and learning, act as a guide to professional development in science departments / faculties as well as providing feedback to the teachers from the students. Differences in response from the teacher's and student's provide a starting point towards an interactive dialogue in teaching and learning and permits the student to take an active role in their engagement with science ideas, the nature of science and scientific literacy.

Although the focus of this paper used the questionnaire data from the secondary students and teachers to reach some conclusions about active learning and engagement in science experiences the project will be analysing the qualitative data from the focus groups to validate the assumptions made here and those made for the Year 1 students and their lecturers group. The authors anticipate that tertiary lecturers will use the responses of the students to modify their teaching and learning programme so as to assist students in making the transition from secondary to tertiary easier. Knowing where the students start and what thinking they bring with them to the university can be used to align existing tertiary science courses to meaningful science experiences.

THE EFFECT OF GENDER AND CONTEXT ON USING WIRING DIAGRAMS AS A TOOL TO REVEAL STUDENT THINKING

James Mackay

School of Mathematics, Science and Technology Education, University of KwaZulu Natal, Private Bag X03, Ashwood 3605, South Africa

mackay@ukzn.ac.za

ABSTRACT

This paper reflects on the use of wiring diagrams as a tool to diagnose student problems in understanding electricity, as well as the gendered effect of context on the performance of students in designing wiring diagrams. Prior to wiring a model house, a sample of 161 primary school teacher trainees were taken through a series of activities designed to teach them basic electricity. They were then asked to design wiring diagrams for both a house as well as a model car. The wiring diagrams were then compared to the initial circuit designs and common errors were then categorised using accepted models of electric current. A smaller, selected sample was then interviewed about the process of designing wiring diagrams for both the cars as well as the houses. Initial findings indicate that students revert to earlier, less scientific models of electricity when confronted with the rather more difficult task of spatially organising the components that need to be connected to fit in with the design of the house/car. In addition, the interviews revealed that the context (house or car) affected female students' attitude and performance on designing a wiring diagram.

Keywords: *Context, conceptual change, gender, diagnostic tool, Electricity, Spatial Visualisation.*

INTRODUCTION

In researching students' conceptual ideas and their attitudes to current electricity tasks, this paper looks at learning basic electrical ideas through a contextualised project, that of wiring a model house. There has been much research into alternative conceptual frameworks in basic current electricity in the last three decades and most of this research has centred around the documentation of these alternative frameworks (Tasker and Osborne 1980; Shipstone 1988). In later years the focus has been on conceptual change strategies and ways to ameliorate particular alternative conceptual frameworks. Hewson (1999) in his paper on teaching for conceptual change, outlines a conceptual change approach to teaching physics that formed the basis of the course that was used as a research vehicle in this particular study. In the course in question, a basic electricity and electronics course for primary school design and technology teachers, I use a process based on work done by Hewson (1999), as well as earlier work done by Gilbert and Watts(1983), Tasker and Osborne (1985) and Shipstone (1988).

In the study I set out to find out what common errors are made when students draw circuit and wiring diagrams and what the possible effect of gender and context is in developing wiring diagrams from circuit diagrams? To do this, the sample chosen was a class of 161 second year design and technology students who were embarking on a single semester module on basic electricity and electronics for teachers. Table 1 below gives a brief profile of the educational background of the class a whole and who they are.

TABLE 1: Profile of the sample class – some statistics

67% female
20% have studied science at high school
55 % are from disadvantaged school background
40% training to be primary school teachers
Design & Technology students are generally not interested in science (physics in particular)

At the start it is important to notice that these are not science students (only 20% did science to the end of high school) and so in general the level of conceptual understanding regarding scientific ideas is not expected to be high. For this reason, the course uses a conceptual development approach (Hewson, 1999) to learning basic electricity.

The sample is also overwhelmingly female, which is to be expected since teaching in South Africa is mostly done by female teachers. (In fact this profile of the class accurately reflects the gender profile of education in South Africa in general. 55% of the class comes from what has been commonly termed a “disadvantaged educational background”. This has been determined using a government approved data base and ranking system which is determined by the relative wealth of the school itself (EMIS Report on School Disadvantage Indicators, 2006). No further attempt has been made to determine the extent of the educational disadvantage.

THEORETICAL UNDERSTANDING

This study draws on literature from three distinct but overlapping areas of Science Education Research. Grounding the study is the wealth of literature on alternative conceptual frameworks as well as conceptual change theory, with particular reference to learning electricity. Related to this I have also looked at issues on spatial visualization since students participating in the project are expected to visualise how a two dimensional circuit “fits” into a three dimensional house and also the conflict between Design and Technology on the one hand and Science on the other. Finally, I believe that there is some connection between the educational / home background of the students, their gender and their performance in design and technology tasks, particularly to do with visualising circuit diagrams in three dimensional spaces. This is played out in the tasks that were set for the students and their general belief in their own abilities to complete them. In the paragraphs below, I will try to link the literature from these seemingly different fields of research.

Electricity and Alternative conceptual frameworks

Understanding conceptual frameworks, especially in the field of physics education has been studied extensively in the past 30 years, Tasker and Osborne(1985) identified a number of different models that learners use in trying to make sense of electric current. These began with a simple *unipolar* approach that negates the need for a complete circuit, to a *dissipative* approach that sees current as a commodity that is being "used up" in the circuit. For learners to have any chance of success in this study, they will need to address their own conceptual frameworks while doing the task. Similar work has been undertaken by Shipstone (1988) and others who go further to developing diagnostic tests to identify such preconceptions. Arons (1981) documents a number of incorrect ideas that persist even after intervention, right until university study. The nature of these mental models that students employ are such that they hinder the conceptual development of any learning of current electricity.

Hewson (1999) advocates a conceptual change approach to the amelioration of alternative conceptions. In this approach he advocates addressing the preconceptions that the learners have through direct intervention using exercises and questioning that exposes preconceptions and puts the learner in a state of conceptual conflict. This approach, based heavily in constructivism is well known and has been used extensively in the teaching of physics in general. (Arons, 1981).

Since the basis of the module is conceptual change and conceptual development, it is important at this stage to outline my philosophy of conceptual development and conceptual change. The module focuses very much on learning to get circuits to work and so the fundamental idea of a circuit needs to be developed. Generally I start the module with a well known activity in learning electricity, where I provide each student with a piece of wire, a torch cell and a light bulb and ask the student to do what they can to light up the bulb. This has a dual effect, the first being that students very quickly work out that the Unipolar model of electric current and hence circuit design as identified by Osborne and Tasker (1985) in the early 80's simply does not work and that for the bulb to light, there need to be at least two connections.

The models of current used as a basis for interpreting circuit diagrams in this study are shown in table 2 below.

TABLE 2 Elementary Models of current (Shipstone, 1988)

Model	Description
Unipolar	Current from only ONE terminal (either positive or negative) No circuit, only a connection from the "power source" to the bulb
Clashing Currents	Both a "positive" as well as a "negative" current meet at the bulb and "clash" causing the bulb to light
Dissipative	Current is "used up" as charge moves around the circuit. Greater current near the (+) pole, dissipating further away from (+) / If negative charge is predominant, current "comes from" (-) pole
Scientific	Current is the same everywhere in a series circuit. For the bulb to light, there needs to be a completed circuit.

Science, Technology and Spatial Visualisation

The completion of the task in this study requires of the students that they visualise the flat 2-dimensional circuit that they have designed using learned scientific principles as fitting into a 3-dimensional space (either a car or a house). In order to do this, the student needs to be able to spatially represent the circuit, a process that requires more of a technological skill than a scientific one. Gilbert, Boulter and Elmer (2000) compare modes of representation commonly used in technology with those used in science. While both disciplines use visual representations like diagrams, Design and Technology makes greater use of concrete modes of representation such as physical scale models. The use of such models requires the learner to transition between 2-D and 3-D thinking in Design and technology much more than it does in science.

Being able to understand and create visual representations such as 3-D diagrams is a cognitive skill that is fundamental to performing well in both Science and Technology. While there has been considerable work done comparing spatial reasoning abilities across cultures, gender and class backgrounds, there has never been any concrete evidence to suggest that it is related to innate ability (Mitchelmore, 1980).The differential performance in science and technology between male and female learners has according to Mammes (2004) been attributed to greater familial encouragement given to boys and the tradition of boys playing games that require spatial abilities.

Issues of diversity - Gender and Educational Background

The differential performance and participation of boys and girls in Science and Technology has received considerable attention worldwide. This study follows from a previous study on the effect of gender and self efficacy on the performance of students on an electrical design and technology task (Mackay and Parkinson, 2010). In that study, it was found while female students were initially reluctant to wire a house and had low self efficacy levels for the task, they performed the same as the male students in the final assessment. There appeared to be no evidence for the effect of context on their performance. According to Lewis (1996), a context-driven approach to curriculum design is distinguished from a content-driven approach in that it takes social, environmental and physical contexts as starting points and uses these to move towards the theories, models and laws that are the starting point of a content-driven curriculum. This task uses the context of building a house to move towards a greater understanding of electrical circuits. Taking students' educational and home background into account, attitudes and levels of self-belief in being able to achieve a technology task are measured before, during and after the task, to see whether doing the task had a positive effect.

Atkinson (2006) found that female learners enjoyed design tasks. This is supported by Silverman and Pritchard (1996) who have shown that building houses is a task that is often favoured by female learners. Lewis (1996), however, points out, that such preferences may be a manifestation of the differential treatment afforded male and female children (including females' primary early socialisation from a parent of the same sex while males are usually socialised by parents of the opposite sex).

It is assumed in this study that differences in participation and achievement of female students in Technology and technological careers do not arise from ability differences, but from social attitudes viewing certain fields as less appropriate for women. These attitudes are embedded in the subtly different ways that male and female children are treated (Nicholson 1984, Smith and Lloyd 1978) and transmitted through discursive practices (Davies 1989).

Many school Technology tasks appear designed to be more interesting to boys than girls (Silverman and Pritchard 1996; Weber and Custer 2005). So it would seem that context is important when choosing a technology task that will be meaningful for girls as well as boys.

DESIGN OF THE STUDY

As mentioned earlier, this is part of a bigger and ongoing action research project where the same tasks are given every year to new students. The main task is the making and wiring of a model dolls house. The choice of a dolls house is elucidated in previous papers from the same study (Mackay and Parkinson 2009 and 2010).

This paper asks two questions.

1. What are the common errors made in drawing circuit diagrams and related wiring diagrams?
2. What is the significance of these errors from a conceptual learning point of view, a spatial visualization point of view and a gender and educational background point of view?

Approach to teaching

There were a number of features to the teaching of this course which are itemized below.

1. *Contextualised Teaching:* The use of a dolls house and a car as two contexts was deliberate in order to see the effect of context on performance in the tasks of drawing circuit and wiring diagrams.
2. *Teaching for Conceptual change:* The fundamental concepts of basic current electricity were taught in such a way that learners were made aware of their conceptual ideas and where change was necessary; they were led to develop their own conceptual frameworks. All conceptual models were tested by the students with their own apparatus. Alternative conceptions were identified and given a name.
3. *Addressing Issues of gender and self Efficacy:* Groups were single sex in order to allow female students to participate to a greater extent than in other classes. Tasks that female students enjoyed (Decorating, making the house) were integrated with tasks they did not enjoy (Connecting circuits, soldering). Students self efficacy was developed by helping students develop their technical skills.
4. *Technology vs. Science:* After developing an initial scientific understanding of electrical concepts, the focus was on getting the circuit to work inside the house and on the necessary design skills. To do this, a wiring diagram had to be developed from the planned circuit diagram.

DATA COLLECTED

While this was in fact part of a much larger study that included data on self efficacy as well as conceptual development and attitude, this study drew on only two data sources.

Drawings of Circuit and Wiring Diagrams

The first was the analysis of wiring and circuit diagrams drawn by students and the second were follow up interviews with students on instances regarding wiring diagrams and conceptual frameworks that they use for predicting and analysing circuits. These data were firstly used to compile a catalogue of common errors in drawing both wiring diagrams and circuit diagrams and then used to probe the effect of context (house or car) on the production of wiring diagrams.

Interviews

Eight students (all female) were interviewed on the tasks they were given. They were selected as interesting candidates because of the diagrams they had drawn. They were then interviewed in an open ended manner in order to elicit their thinking behind why they drew the diagrams they did as well as the relative difference in difficulty between the house task and the car task. The interviews were recorded and then transcribed.

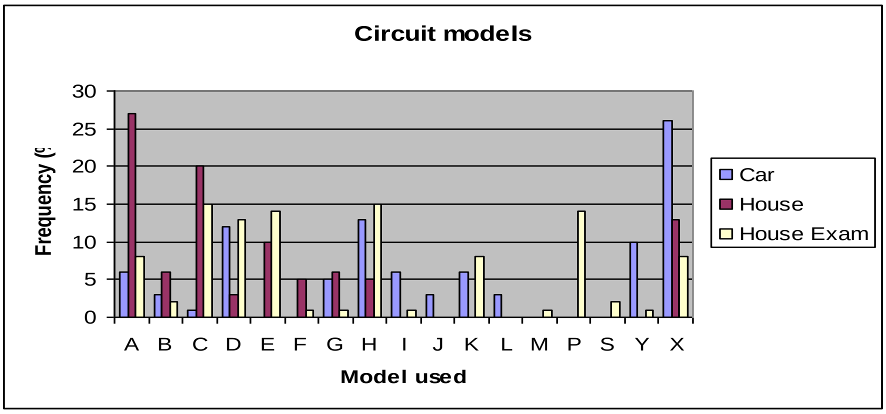
MAIN FINDINGS

Common Errors

Generally, students were happy to draw circuit diagrams and had in fact learned to do this fairly competently, one assumes as a result of the programme of study prior to the final task given. The drawing of wiring diagrams presented some difficulty to a number of the students in the module, as outlined by table 3 which records the relative frequency of the common errors made. The catalogue and analysis of common errors in the drawing of wiring diagrams as well as circuit diagrams is listed below:

Error Frequency

The frequency of these errors is shown in the histogram below, which also distinguishes between the context in which the errors were made. Students were asked to draw both circuit and wiring diagrams for both the house and the car. There were also several questions on circuit diagrams as well as a wiring diagram for a house in the final examination and the relative frequency of these errors in the examination is also recorded. The meanings of each model used are indicated in table 3.



Specific frequencies of the errors found are given in table 3 below

Table 3: Ranking common errors by total frequency

	Context				
Common Error	Car	House	House Exam	TOTAL	Description of Common Error
A	6	27	8	41	Unipolar thinking used when drawing the wiring diagram (WD)
C	1	20	15	36	Short circuit wires present in the CD
H	13	5	15	33	Simple series connection portrayed as WD
D	12	3	13	28	Components "left hanging" in the WD (perhaps as a result of unipolar thinking)
E	0	10	14	24	Short circuit wires in the WD
K	6	0	8	14	Non functional loops in the circuit (A version of the short circuits)
P	0	0	14	14	No power in the circuit
G	5	6	1	12	Wiring follows house layout (spatial visualization problems)
B	3	6	2	11	Draws the Circuit Diagram (CD) as the wiring diagram (WD)
I	6	0	1	7	Draws the WD as the CD
F	0	5	1	6	Main switch in parallel with the battery (A version of the short circuiting)
J	3	0	0	3	WD more accurate than CD
L	3	0	0	3	Parallel CD / Series WD (Same as H above but with a definite difference)
S	0	0	2	2	Switches for parallel circuit wrongly placed.
M	0	0	1	1	More than required connections to lamp / component
Y	10	0	1	11	Other mistakes
TOTAL					
X	26	13	8	47	Did not complete

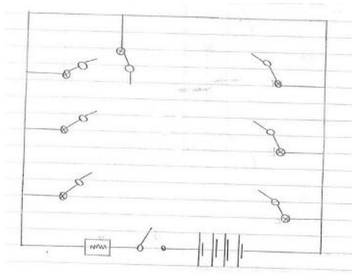
Interpretation of Common Errors

These data will be interpreted in two ways. The first is to simply look at all the errors that were made in all three tasks and try to link them with other errors and then find ways to interpret the thinking behind them. This was to be supported by the interviews, but in the end, the interviews only provided us with some insight into the attitude the students had with different tasks. This will be discussed later.

The second interpretation is to compare the performance on the three different tasks. As can be seen from the graph and table, the contexts of house and car affected the students' performance. For this, interview data was helpful in ascertaining the reasons for this differential performance.

Trend 1: Unipolar wiring Diagrams; Completed circuit diagram(A)

Apart from those students who did not complete the task, all students other students provided a completed circuit as their circuit diagram. This is not surprising as gave as a circuit diagram the correct parallel circuit. In drawing this circuit, they correctly drew the positions of the power source used, the switches and the components (lights and motors). It is clear that when it comes to drawing the wiring diagram, students revert to previously held unipolar ideas about how circuits work. This is the most common error when it comes to the wiring diagram of the house, which was a major project on the course. What is interesting is that this is not the most frequent error in the similar task, the wiring of a car. Here, the most frequent error is H, the use of a simple series circuit in drawing the wiring diagram.



Trend 2: Fewer errors in the car diagram of error A and error C

The car task came after the house task and perhaps there was an improvement if there were fewer errors, however, the large number of those students who did not complete the task indicates that this is probably not the case.

Trend 3: A greater number of students did not complete the car task than the house task

This is put down to the context being different. Essentially, the task was the same nd called for the same parallel circuit to be designed into the space of a car in this case and not a doll house. This could easily be due to lower levels of self efficacy amongst female students. Of the eight students that were interviewed, all were female and all but one expressly indicated that the fact that the context was a car made the task difficult or impossible. The one female student who indicated that the context did not matter, described herself as a "tomboy" who loved "boys games. She described her social and sporting life as being mainly to do with action oriented "boys things" Interestingly, the house she chose to design for the house task was a fire station.

Common responses to the car task were:

"This is impossible – how do we know about cars. This is for boys"

“I found it difficult, because I don’t know about cars, I am a girl”

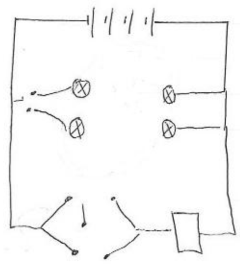
Trend 4: Drawing the correct parallel diagram for the circuit, but a unipolar design for the wiring diagram.

This was to be found in both the house task as well as the car task. Four such examples are shown below.The interviews did not reveal anything definite, except that all agreed that drawing the circuit was easy, but “putting it into the house / car” was hard. The students had all managed to design an appropriate circuit and connect it on a flat table, but the three dimensional visualization necessary for designing the wiring diagram appeared to be too hard.

<table>
<tr>
<td>

Example 1

D Components left hanging / unipolar model (car)

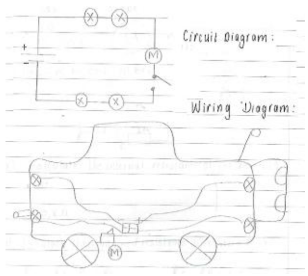


In this example, components are left hanging. This is an interesting circuit, because the power is in fact connected to the components. One component is connected in a “circuit –like” loop, with the bulbs connected in a unipolar fashion. This student simply could not explain why they drew it like this

</td>
<td>

Example 2

A: Unipolar wiring diagram (car)

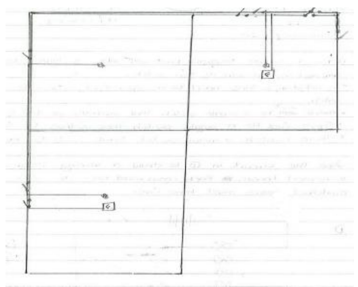


This is an example of a unipolar wiring diagram for the car task. The circuit diagram is wrong of course. It should be a parallel circuit, but one can clearly see the unipolar nature of the wiring diagram

</td>
</tr>
<tr>
<td>

Example 3

A: Unipolar wiring diagram (house)

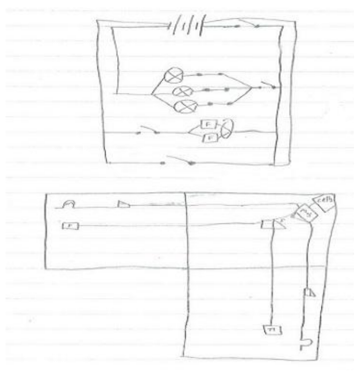


This is a clear use of the unipolar model in drawing the wiring diagram for a three roomed house.

</td>
<td>

Example 4

A: Unipolar wiring diagram (house)

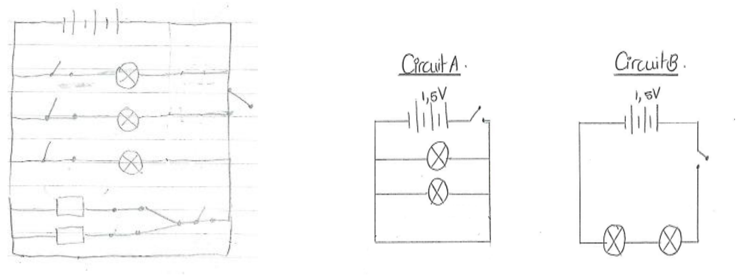


This example clearly shows a parallel circuit which also incorporates an unnecessary short circuit across the terminals of the battery. The wiring diagram for the same circuit is also unipolar by design

</td>
</tr>
</table>

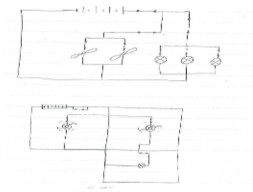
Trend 5: Short circuits

This is shown in common errors C, E, K and F. In these instances which have been separated, there are inexplicable short circuits drawn into the mainly the circuit diagrams, but also the wiring diagrams on occasion (E). The interviews revealed no reason for this, except one student remarked that it made the circuit “neater”. An example of this error is shown below.



Trend 6: Reverting to a simple series circuit when drawing the wiring diagram.(H)

This error was also relatively common. In the example shown below, a student has drawn the correct parallel circuit for the circuit diagram (although standardized component symbols have not been used). This has led however to a much simpler version of the wiring diagram, a series circuit. Although the series circuit will work, it is not a good design and also not the same circuit that this student actually used in the wiring of the house. The student wired the house correctly with a parallel circuit, but was unable to integrate the parallel circuit into the spatial representation of a three roomed house.



Trend 7 Using the circuit diagram as the wiring diagram (B)

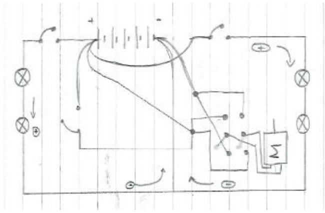
This I think is also a consequence of poor spatial reasoning and development. Although this was not confirmed by the interview data.

Trend 8 No power source in the circuit

This was a minor error. Sometimes the circuit was correct, except for the fact that there was no power connected.

Trend 9: Use of the clashing currents model(car)

This wiring diagram for a car clearly shows how the student has designed the circuit with regard to the movement of charge in the circuit. This is best described in terms of the clashing currents model.



DISCUSSION

Students showed poorer performance in developing wiring diagrams than circuit diagrams, along with regression to unipolar models of design as well as (in fewer cases) simple series circuits, suggesting that when students are asked to plan a circuit spatially, they retreat to models of thinking that we as teachers believe they have "left behind". This could be related to poor spatial visualisation that has been found in other literature to be common in non-science majors and learners from educationally disadvantaged backgrounds.

Interviews with selected female students who drew wiring diagrams suggest that context has an effect on whether or not female students feel able to design circuit and wiring diagrams. This is supported by evidence from similar tasks given where the circuit remained the same, but the context was changed. Female students reported that they felt less able to design a wiring diagram for a car. It was seen as a male domain.The pattern of errors for the car wiring diagram was different from the house wiring diagram, suggesting that students (predominantly female) found this more difficult than they did for the house. Low self efficacy levels amongst female students in terms of spatial visualisation could have led to regression to unscientific thinking when it came to designing the wiring diagrams.

In conclusion, the wiring diagram is a useful diagnostic tool for eliciting "hidden" non scientific ways of thinking as well as addressing issues of spatial visualization, context and gender in the learning of electricity.

ABSTRACT

This paper describes the Latin-American Project on the Evaluation of Attitudes Related to Science, Technology, and Society (PIEARCTS), an international cooperative educational research aimed to evaluate students' and teachers' beliefs on STS issues, as a central part of scientific literacy for all. This general aim unfolds into identify the strengthens, the weaknesses and the necessities, which influence STS learning, as well as to improve the teaching and learning of STS issues through the planning, the design and the innovation of science curriculum, and teacher training. As an illustration of the evaluation aim, the STS thinking of teachers from scientific and non scientific specialties is presented. The results show neutral, lightly positive global attitudes, and the detailed analysis allows identifying the teachers' positive and negative beliefs. The comparisons between science and arts teachers show that science teachers' attitudes are just slightly better than those of the art teachers, yet lacking statistical signification. The implications of these results for the teaching of the nature of the science and technology and for the training of science teachers are discussed.

Keywords: *nature of science and technology*, *science-technology-society, scientific and technological literacy, attitude evaluation, teacher thinking.*

INTRODUCTION

Scientists, educators and international organizations of education in science and technology (S&T) agree that the learning and development of informed and appropriate conceptions on S&T and their relationships to society (STS), so called nature of science and technology (NoS&T) topics, is an essential indicator of S&T literacy for all (Lederman, 1992).

The nature of science and technology (NoS&T) is a meta-cognition that arises from the reflections of philosophers, sociologists and historians, scientists, teachers and experts in science education. The core of this reflection embraces quite different issues although they can be summarized as what science is, how it internally works, how it is developed, how it builds knowledge, how it relates to technology and society, what values scientists use in their work, etc. (Acevedo, Vázquez, Manassero & Acevedo, 2007).

A great amount of research has examined pre-service and in-service science teachers' NoS&T conceptions in the last years. The studies consistently report that teachers possess inadequate conceptions of NoS&T, which are inconsistent with modern views of science and scientific practice. They suggest that teachers do not understand NOS, and they show large proportions of teachers holding traditional positivistic, idealistic views of science and technology and their interactions within society. For example, many teachers believe that scientific knowledge is not tentative, conceptualize science as a body of knowledge or identify science with a discipline (physics, chemistry or biology), portray technology as applied science, conceptualize scientific hypotheses, theories and laws in a developmental sequence, etc. (Abd-El-Khalick & Lederman, 2000; Abell & Smith, 1994; Gallagher, 1991; Haidar, 1999; Hammrich, 1997; King, 1991; Lederman, 1992; Lederman, Schwartz, Abd-El-Khalick & Bell, 2001; Pomeroy, 1993). Most of the research on teachers' conceptions of NoS&T has been focused on secondary and pre-service science teachers rather than on primary, university, in-service or non-science teachers.

The Latin-American Project of Evaluation of Attitudes Related to Science, Technology and Society (Spanish acronym, PIEARCTS) is an international cooperative investigation (http://www.piearcts.com.ar/) that aims to diagnose the students' and teachers' beliefs and attitudes on STS topics in seven Latin-speaking countries (Spanish and Portuguese). The PIEARCTS planned sample embraces three main groups: students in their last year of high-school or first year of college (18-19 year-old), undergraduate students in their last year, with special attention to those involved in pre-service teacher training (22-23 year-old), and practitioner teachers in primary, secondary and higher education.

This paper depicts the practitioner teacher's NoS&T conceptions, which are assessed applying a paper and pencil questionnaire to a large sample of teachers from science and non-science (art) backgrounds. The research questions are twofold: Which are the strengths and weaknesses of practitioner teachers' thinking on NoS&T? Is practitioner science teachers' understanding on NoS&T better than their counterpart practitioner art teachers?

Table 1. Dimensions of science and technology issues that develop the 30 COCTS items applied through the two instruments (form 1 and form 2).

METHOD

Sample

The sample involves 822 practitioners teachers, who belong to all educational levels (primary, secondary and university), science-technology and art specialties, men and women, and represent an approximate population of 42000 practitioners. About 72% of teachers have got a science or engineering specialty, (28%, arts or humanities), 59% are men (41% women). The overall sex distribution varies depending on the group, as science group displays 74% men, while the group of humanities just has 41% men. The teachers' age spread from 23 to 76 year-old. The teachers answered 30 COCTS items distributed in two questionnaire forms (to let the response time maneagable) that were ramdomly applied to the whole sample by halves; so that 390 teachers validly answered the form 1 and 432 teachers answered the form 2.

Instrument

The PIEARCTS uses the Questionnaire of Opinions on Science, Technology and Society (Spanish acronym, COCTS), an empirically developed pool of 100 multiple-choice questions, credited as one of the best paper and pencil instruments to evaluate STS beliefs as its empirically developed construction warrants the item validity (Aikenhead & Ryan, 1992; Rubba, Schoneweg & Harkness, 1996). The STS topics are structured into the following COCTS dimensions (table 1): Definitions of S&T, external sociology of S&T (influences of Society on S&T, influence of S&T on Society), education in S&T, internal sociology of S&T, and epistemology.

The items display a general multiple choice format. Each item stem presents a specific NoS&T issue using a common and simple language within a non-technical style (table 2). A variable number of sentences, each labelled with a letter A, B, C…, follow the stem text; each sentence states a particular reason that explains a position (belief) on the stem issue (Manassero, Vázquez & Acevedo, 2003).

Table 2. Text of the item 40211 that addresses the issue about the decision maker on social issues related to science and technology (Influence of S&T in society).

40211 Scientists and engineers should be the ones to decide what types of energy our country will use in the future (for example, nuclear, hydro, solar, or coal burning) because scientists and engineers are the people who know the facts best.
Scientists and engineers should decide: A. because they have the training and facts which give them a better understanding of the issue. B. because they have the knowledge and can make better decisions than government bureaucrats or private companies, both of whom have vested interests. C. because they have the training and facts which give them a better understanding; BUT the public should be involved — either informed or consulted. D. The decision should be **made equally**; viewpoints of scientists and engineers, other specialists, and the informed public should all be considered in decisions which affect our society. E. The **government** should decide because the issue is basically a political one; BUT scientists and engineers should give advice. F. The **public** should decide because the decision affects everyone; BUT scientists and engineers should give advice. G. The **public** should decide because the public serves as a check on the scientists and engineers. Scientists and engineers have idealistic and narrow views on the issue and thus pay little attention to consequences. H. It **depends** of the type of decision; it is not the same thing to decide on the nuclear disarmament or on a baby. In some cases the scientists could make the decision, but in other, the citizens or the stakeholders should make it.

Some 30 items is drawn from COCTS by the PIEARCTS research team after a consensus process to design the two forms (F2 and F2) applied to teachers. The main design criteria of questionnaires were a balanced coverage of the COCTS dimensions and a manageable answering time for surveyed people. Some reliability indexes of this application will be produced in the Symposium.

Procedures

The questionnaire forms were answered by teachers through a self-administration process by means of a web-resident application. The participants are not asked to choose any of the multiple choice statements, rather they are asked to rate their agreement (1, total disagreement; 9, total agreement) on each item statement (called the multiple response model). These agreement direct scores are transformed through a scaling metric described elsewhere (Vázquez & Manassero, 1999; Vázquez, Manassero & Acevedo, 2005) into homogeneous attitudinal-belief indexes (-1, +1), which are invariant across all sentences, categories and items. The index meaning states that the higher (lower) the index, the higher (lower) the belief's appropriateness according to the current knowledge from history, philosophy and sociology of S&T.

The indexes are quantitative parameters that allow computations and the application of inferential statistics for hypothesis testing, which can be applied to compare groups or to set up cutting points for levels of achievement in index scores (Vázquez, Manassero & Acevedo, 2006). To this aim the effect size of the differences (differences measured in standard deviation units) is applied along with a criterion to achieve relevance (size of the difference higher than a third of the average standard deviation). The difference between groups is considered relevant when its effect size is higher than .30 (of course, the relevant differences are almost always statistically significant, $p < .001$).

The NoS&T attitudes and beliefs on each item are computed as a weighted mean of their statement indexes allowing to get the most positive, the most negative, and the neutral beliefs, which identify the strengths and weaknesses of the NoS&T thinking on each issue. This is a very useful information to improve teacher training on these issues.

RESULTS

The global average of the 30 applied items for the whole sample of teachers (m = .0199; SD = .273) is roughly a null value. This parameter is interpreted as a neutral global attitude for the teachers on the whole STS issues represented by the set of 30 applied items. The positive beliefs are compensated with the negative ones to produce this approximately neutral average for the whole sample, which suggests that some informed beliefs cohabit with less informed ones, yet overall are not positive (table 3).

Each items' global index is the most specific general indicator of teachers' positions on the diverse NoS&T topics outlined in each of the 30 items. The items' indexes display somewhat balance between positive and negative values, as the same number of items approximately display positive and negative values. This is the first indicator of balance among positive and negative visions which produces the whole neutral disposition (table 3).

The items displaying the best (highly positive) or the worse (highly negative) indexes are identified through the application of the effect size criterion in relation to zero score. Applying this approach, the following items have got the best (more positive) indexes (in descending order):

F1_40161 Social Responsibility contamination
F1_30111 STS Interaction
F2_50111 Union two cultures
F2_20511 Educational Institutions

F2_60521 Gender equity
F1_10411 Interdependence
F2_40131 Social Responsibility Information
F2_10421 Interdependence Quality of life
F1_10111 Science
F1_20141 Government politics a country
F1_40221 Moral Decisions
F1_60611 Women under representation
Applying the same effect size criterion, the following items have got the most negative indexes (in descending order):
F2_70211 Scientific Decisions
F2_10211 Technology
F1_20411 Ethics
F2_40421 Application to daily life
F1_40531 Life Welfare

Table 3. Global mean indexes of the 30 items for the whole sample of surveyed teachers sorted by their mean value.

F1_40531 life welfare	369	-0,336	0,387

On the other hand, the questionnaire and the method allow inferential statistics, whose power could be illustrated through the comparison between science and art teachers. Taking into account the different background specialization on S&T between science and art teachers it should be hypothesized that science teachers would show significantly better NoS&T understanding than art teachers, that is to say, science teachers' indexes would be significantly higher than art teachers' indexes.

Nevertheless, the most remarkable finding of this overall comparison on the mean item indexes of both groups shows that both appear more equal than different (table 4), contradicting the former hypothesis. Only one out of 30 items (the item about moral decisions) displays an effect size between the groups higher than the minimum cutting point (> 0.3) to be considered a relevant difference; the remaining 29 items display effect size scores that get positive and negatives values, although they can not be deemed significant enough for relevance.

The overall comparison among groups shows that science teachers' conceptions tend to be better than their art counterparts, who lack scientific training, yet the differences between the two groups are not statistically relevant. Thus, in spite of the deeper enculturation in S&T of science teachers, the results can not allow for claiming that science teachers' understanding of NoS&T be significantly better than art teachers' understanding.

Furthermore, this empiric method also allows unveiling some specific NoS&T issues where the art teachers exhibit more appropriate attitudes than science teachers (8). The presence of eight negative effect size item scores means that art teachers over score science teachers in these items, that is to say, science teachers' beliefs are worst than art teachers in these NoS&T specific issues.

The 8 items in the bottom of table 4 account for those issues where art teachers' indexes are better than science teachers. Curiously, half of these items (4) belong to the epistemology dimension, deemed crucial for understanding some key features of S&T; the epistemology dimension is the most representative of the intrinsic values of S&T as a way of knowing and crafting the natural world. So, art teachers display better understanding in a significant number of epistemology items, which represent more than half of the whole epistemology items (7) teachers answered in the questionnaires.

Table 4. Global mean indexes of the 30 items for the groups of science and art teachers sorted by its effect size value.

Summing up, the comparison between science and art teachers displays the surprising finding that science teachers do not clearly beat art teachers on understanding NoS&T as could be expected, taking into account their higher enculturation in S&T. Yet, art teachers overscore science teachers in some (8) out of 30 items.

DISCUSSION

This paper describes the general in-service teacher thinking about some NoS&T issues, which is an absolute assessment of teachers' understanding, and a comparison between science and non science teachers, an unusual and relative assessment in science education, which is mostly focused in science teachers (Akerson & Volrich, 2006). Teacher thinking is assessed by means of a wide paper and pencil instrument and a sophisticated quantitative procedure that allow quick applications to large samples and performance of inferential statistical analysis for hypothesis testing (Vázquez, Manassero & Acevedo, 2005, 2006).

Although one would expect that teachers would show positive indexes overall items, this is not the case in these results. The first finding highlights the overall teachers' poor understanding about NoS&T issues. The score indexes along the 30 issues in NoS&T items spread from positive to negative displaying a kind of symmetrical balance among them and lower scores than expected, when positive. Just a bunch of items (11 items, about 33%) display positive indexes (low scores), which could be deemed an acceptable low adequate understanding of NoS&T, while the big majority of items represent an insufficient negative understanding of NoS&T; further, any of the the highest indexes are actually high.

The teachers' weaknesses, which agree with other studies, (Bell, Lederman & Abd-the-Khalick, 1998; Akerson & Volrich, 2006; Khishfe & Abd-the-Khalick, 2002), point out to the specific NoS&T contents to be included in science teacher training on NoS&T to improve teachers' understanding of NoS&T. When considering only the science teacher group, eliminating the art teachers, the previous coments remains almost the same and valid.

Overall, it should be expected that science teachers' indexes would be significantly higher than art teachers' indexes, given the higher background specialization on S&T of science teachers when compared with art teachers, who lack scientific training. Although the second and most important finding underlines that science teachers' NoS&T conceptions tend to be better than their art counterparts, the mean item index differences between science and art teachers are not statistically relevant. This lack of signification suggest that science and art teachers appear more equal than different, so the commonsense expectation about the superiority of science teachers could be considered empirically falsified. In spite of the deeper enculturation in S&T of science teachers, they do not significantly exhibit better understanding of NoS&T.

An straightforward interpretation of this equality between science and non-science could suggest that the scientific training delivered to S&T teachers through undergraduate canonical lessons, practical work and scientific inquiry is not effective to achieve more appropriate NoS&T conceptions than art teachers (Lederman, 1999). This interpretation has direct and urgent implications for teacher training nowadays: as the science education renovated curricula and current research aim to achieve the scientific and technological literacy for all, and NoS&T is a key component of literacy, teachers must be well trained to teach NoS&T (Duschl, 2000; Schwartz, Lederman & Crawford, 2004).

These findings want also to illustrate researchers about the power of the methodology based on COCTS items applied in the PIEARCTS project. The empirical quantitative method produces attitudinal invariant standardized item indexes, which diagnose the teachers' strengthens and weaknesses on NoS&T conceptions and understanding, as well as to perform statistically hypothesis testing in group comparison and more wide comparisons such as comparisons among different research studies that qualitative methos do not allow at all.

All in all, the main finding suggests that the undergraduate scientific education is not effective for graduates in S&T to learn and understand appropriate ideas on NoS&T issues. This claim points out a prospective aim for teachers: the undergraduate education and the specific initial science teacher training must be deeply innovated including effective NoS&T teaching to facilitate the acquisition of informed views on NoS&T the teachers.

Research Project SEJ2007-67090/EDUC funded by the Education Ministry (Spain).

ABSTRACT

This paper presents a cross-level approach researching German chemistry student teachers` beliefs about teaching and learning. The study is based on student drawings which show commonplace teaching situations. These drawings were analyzed with an evaluation pattern which was developed using Grounded Theory. The pattern included three qualitative scales: beliefs about classroom organization, teaching objectives, and epistemological beliefs. This paper compares the beliefs found within different groups of student teachers at different stages of their teacher training program. The data presented here was taken from freshman student teachers, student teachers in the middle of their teacher training program, and student teachers in compulsory in-service training, which occurred after the participants had finished their university program. Each group was composed of circa 30 student teachers. The results suggest that freshman student teachers profess more traditional beliefs about chemistry teaching and learning that are characterized e.g. by teacher-centeredness and receptive learning. Chemistry student teachers halfway and all the way through their teacher education program at the university level hold more modern beliefs about teaching and learning. Comparing these two groups, the first group's beliefs seem to be the most strongly modern in character. Implications for teacher education are also addressed.

Keywords: *Chemistry Student Teachers` Beliefs, Cross-Level Study, Chemistry Teacher Training Program, Grounded Theory*

INTRODUCTION

In recent decades science education research has focused more and more on (student) teachers` beliefs. We know that educational reform will only succeed if teachers` beliefs, their knowledge and their attitudes are taken seriously into account and correspondingly incorporated into reform efforts (Nespor, 1987). Bandura (1986) stated that beliefs tend to be the best indicators for one's personal behavior. Koballa, Gräber, Coleman, and Kemp (2000) concluded that beliefs influence all types of interactions between teachers and pupils. Although there has been - up until now - little evidence giving a clear picture of the relationship between a teacher's beliefs and her/his actions and impact on students' learning, there is a consensus among researchers that teachers' beliefs permanently influence their teaching practice (Clark and Peterson, 1986). Thus, many scholars view knowledge about teachers` beliefs as crucial when attempting to affect teachers' actions, including their beliefs concerning both teaching and learning (e.g. Ben-Peretz, 1984; Fischler, 2000).

Pajares' review from 1992 illustrates that beliefs play a crucial role in defining personal behavior and in organizing knowledge and information. Taking this one step further, we can assume that student teachers` beliefs affect both their learning and their understanding of teaching through every step of their teacher education program (Fischler, 2000).

In our understanding, teachers' beliefs' are a weak but inclusive construct which covers any mental predispositions a teacher or student teacher holds and which affects his/her behavior in classroom situations. These beliefs stem from personal experience, knowledge or social background (Markic, 2008; Markic, Valanides & Eilks, 2008).

Some research on science student teachers` beliefs and the differences between teachers from different scientific disciplines is already available (see e.g. in Markic & Eilks, 2008). Tsai (2002) categorized student teachers' beliefs about teaching, learning, and science as traditional, process-oriented, or constructivist. The results of his study show that the majority of 37 Taiwanese science teachers held traditional beliefs. More importantly, over half of these student teachers held beliefs about teaching, learning and science that were closely aligned to each other. Koballa et al. (2000) described German chemistry student teachers' beliefs as reproductive rather than constructive. Boz and Uzuntiryaki (2006) found that the majority of twelve Turkish chemistry student teachers held intermediate beliefs (transitional between traditional and constructivist) about teaching. Simmons et al. (1999) also showed that beginning teachers hold a wide variety of beliefs about teaching (teacher-centered, student-centered and/or conceptual) and that these beliefs are not very stable. Nevertheless, such beliefs were found to be not fully developed or clearly reflected in many instances.

There are relatively few studies concerning the development of the student teachers` beliefs and most of them focus on a comparison of student teachers` beliefs before and after special courses. Skamp and Mueller (2001) showed that student teachers in Primary school science have entry-level beliefs espousing teacher-dominated teaching and learning frameworks. Such students did not appear to change their opinions during their teacher education program. Hewson, Tabachnik, Zeichner, and Lemberger (1999) found that the development of student teachers` beliefs depends largely on coursework at the university, cooperative teachers, curricula, and the school environment. Veal and Hill (2004) evaluated one pre-service and one secondary chemistry teacher's beliefs during methodology courses, practical experience, and a student teaching internship. The study concluded that teachers` beliefs concerning content went unchanged, whereas those about teaching did evidence changes.

The purpose of this study is to provide a snap-shot of the beliefs prevalent among prospective chemistry teacher-trainees at different stages of their training program. Using a cross-level approach, this study researched three different groups: freshman student teachers of chemistry, student teachers halfway through their 5-year university teacher training program and a group of young chemistry teachers during compulsory in-service training after they finished their university program. All of the groups stemmed from the same educational and regional background. Our research questions were:

- *Which beliefs do chemistry student teachers hold about chemistry teaching and learning at the different stages of the chemistry teacher education program in Germany ((i) freshman chemistry student teachers, (ii) chemistry student teachers in the middle of their university teacher training program, (iii) young chemistry teachers in their compulsory in-service training after having finished the university program)?*
- *Are there any similarities and/or differences in the chemistry student teachers` beliefs about teaching and learning at the different stages of their chemistry teacher education program*?

SAMPLE

The sample consists of three different groups of prospective chemistry teachers from Northern Germany. The first group is composed of freshman chemistry student teachers (N=44). Data collection took place within the first two weeks of their university teacher education program, which was the start of higher education for to nearly all of the participants. Thus, these student teachers had not had any university courses prior to this study and had not been previously influenced by either university coursework or professors. The second group of student teachers (N=31) was halfway through their 5-year university education program (average 5th semester). This group had already had several chemistry lecturers and seminars, including some education and science education courses. The participants had just returned from a half-year teaching internship in school. The third group is made up of young chemistry teachers who had finished their university teacher training program and were taking part in an obligatory 18-month in-service teacher training period (N=20). These student teachers taught both chemistry and a second school subject for about 12 classroom periods a week, and additionally were required to complete 3-4 hours of pedagogy and chemistry education seminars each week as part of their teacher training. Some characteristics of the participants are presented in Table 1.

Characteristic	***Options***	***Freshmen (N)***	***5th semester (N)***	***End (N)***
Age	under 21	24	0	0
	21 – 25	11	23	0
	25 – 30	7	3	15
	over 30	2	5	5
Sex	Female	28	14	11
	Male	16	17	9
Federal State of Germany where secondary education completed	Bremen	6	8	11
	Lower Saxony	32	16	7
	North Rhineland – Westphalia	1	1	1
	Schleswig – Holstein	0	2	1
	Other	4	3	0
Type of school where secondary education completed	Grammar school	34	26	19
	Comprehensive school	6	4	0
	Other	4	1	1

Table 1: Selected characteristics of the participants in the study

The selection of this data sample is not representative in statistical terms. Nevertheless, most of these German student teachers have (i) similar formal qualifications for university access, (ii) comparable age and gender distributions and (iii) comparable university chemistry teacher education as on different German universities. Using this point-of-view as a springboard, there is no sound reason for us to assume that these chemistry student teachers are special in any respect. There can be no logical assumption that the results would differ notably by sampling a new test group from any other subset of German universities.

METHOD

In this study the participants were instructed to draw themselves as chemistry teachers in a typical classroom situation, and then answer four open-ended questions. This idea drew upon the 'Draw-A-Science-Teacher-Test Checklist' (DASTT-C) (Thomas, Pedersen & Finson, 2001) supplemented with further questions about teaching objectives, and prior activities (Markic et al., 2008). The data analysis pattern was developed using the beginning steps of Grounded Theory (GT) for generating categories out of the data (Markic et al., 2008). The range between the predominance of more traditional and more modern beliefs was selected as the core category based on GT. Three 5-step scales were developed, which focused on 1) *Beliefs about Classroom Organization*, 2) *Beliefs about Teaching Objectives* and 3) *Epistemological Beliefs*. Short descriptions of these three scales are presented in Table 2. The validity of the data was achieved through independent rating and searching for inter-subjective agreement (Swanborn, 1996).

	Traditional beliefs		*Modern beliefs*
Belief about Classroom Organization	Classroom activities are mostly teacher-centered, -directed, and -controlled and are dominated by the teacher.	↔ -2, -1, 0, 1, 2	Classes are dominated by student activity and students are (at least partially) able to choose and control their activities.
Belief about Teaching Objectives	The focus of chemistry teaching is more or less exclusively focused on content learning.	↔ -2, -1, 0, 1, 2	Learning of competencies, problem solving or thinking in relevant contexts are the main focus of teaching.
Epistemological Beliefs	Learning is passive, top-down directed and controlled by the dissemination of knowledge.	↔ -2, -1, 0, 1, 2	Learning is a constructivist, autonomous and self-directed activity.

Table 2: An overview of the scales from the qualitative part

RESULTS AND DISCUSSION

All three categories were interpreted as representing a spectrum between more traditional and more modern beliefs with regards to educational theory and research evidence (see Markic, 2008).

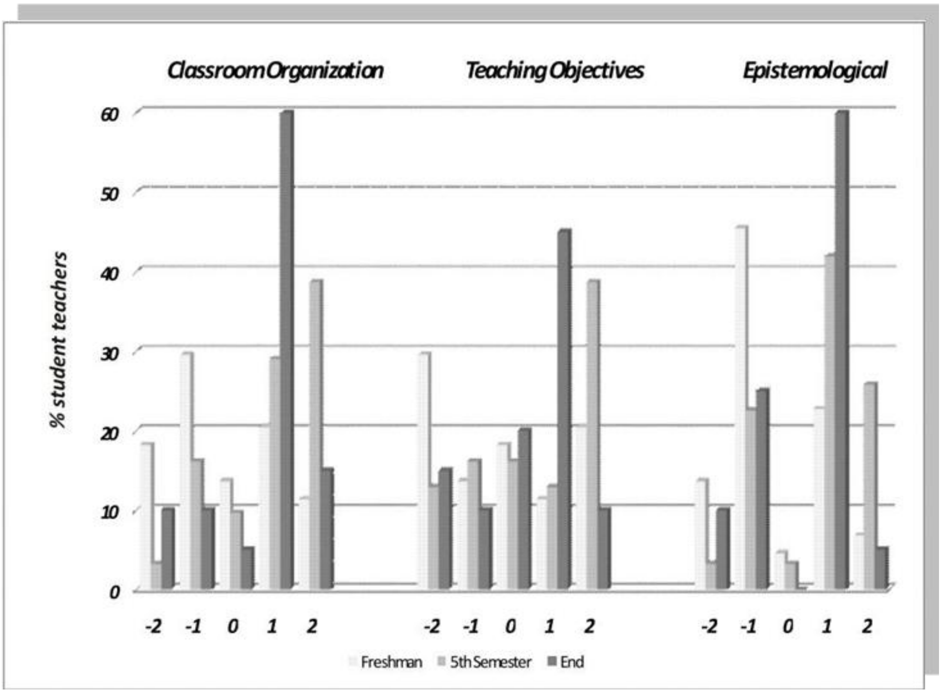

Figure 1: Visualization of the percentages for the three categories

The results in Figure 1 indicate a broad diversity of beliefs within the groups as a whole, but also show contrasts within the respective subgroups of chemistry student teachers. The 41 freshmen possess a wide range of beliefs about themselves as teachers and about chemistry teaching and learning. These student teachers evidenced a slightly more noticeable tendency towards traditional beliefs in all three categories as compared to the group as a whole. The 5th semester student teachers and those at the end of their university teacher training program tended to hold more modern beliefs when it comes to chemistry teaching and learning. The analysis of the 5th semester student teachers shows heterogeneous allocations for all three categories, but especially for *Beliefs about Teaching Objectives.* In the other two categories, this group leaned quite strongly towards student-centered and constructivist learning.

The group of student teachers at the end of their teacher education program expressed also more modern beliefs about teaching and learning. Their allocation of codes is noticeably more homogeneous. Concerning their *Beliefs about Classroom Organization* and *Epistemological Beliefs,* roughly 60% of this group emerges as being rather student-centered and quite constructivist when it comes to the question of learning. Although both the second and third groups profess more modern beliefs about teaching and learning in general, there is a difference between them. Whereas a large number of the student teachers halfway through their teacher training program had both strongly student-centered beliefs and strongly constructivist learning beliefs (both categories coded with a value of ‘2’), the student teachers at the end of their university training program hold to these beliefs less strongly (coded with values of ‘1’).

Another important aspect of the data is related to interpreting the data combinations found among the three categories. If a student teacher shows similar classifications in each of the three categories, then the combination of codes will appear along or near the diagonal line from (-2/-2/-2) to (2/2/2) in Figure 2.

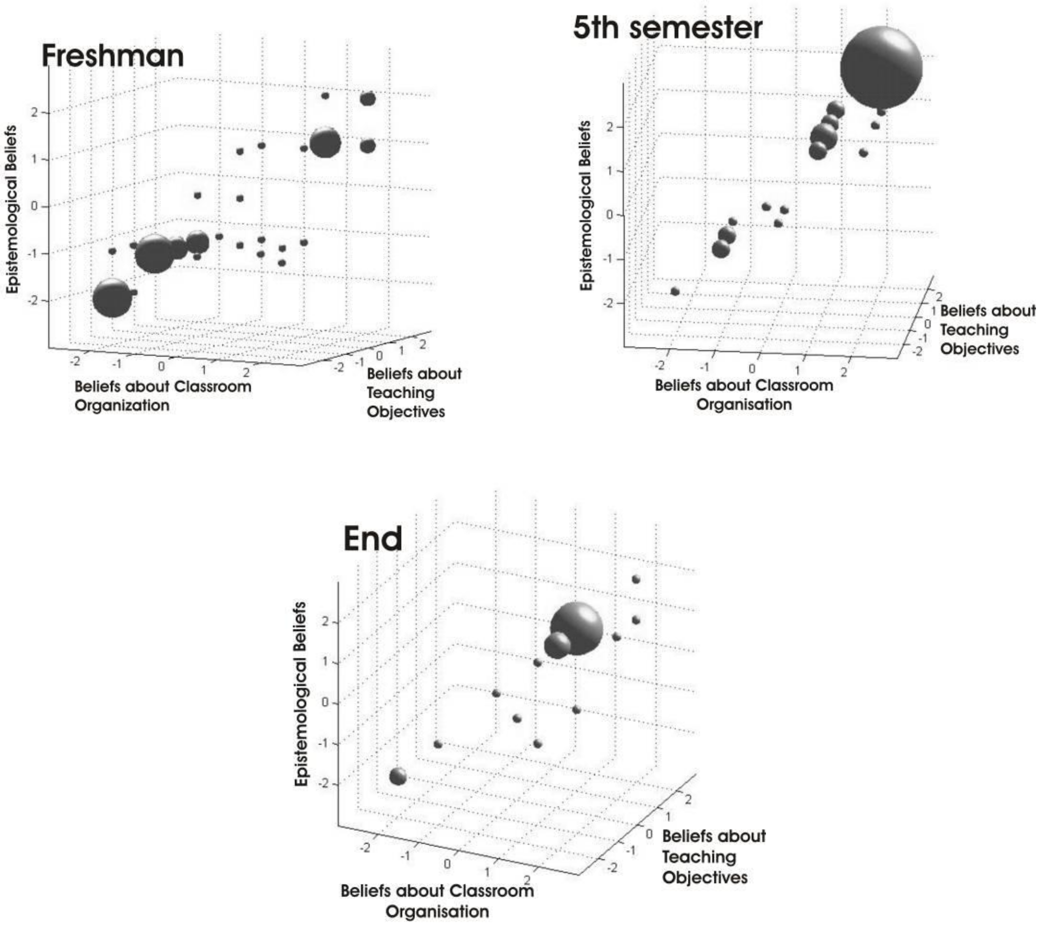

Figure 2: 3D-representation of the code combinations

Figure 2 shows a high proportion of student teachers’ code combinations occurring near the spatial diagonal. This means that the beliefs tested are interdependent upon one other (see also Markic & Eilks, 2008). Furthermore, the closer a student teacher’s code combination approaches the lower, left, frontmost portion of the three-dimensional plot, the more traditional the student teacher’s beliefs about teaching and learning will be. The nearer a code combination approaches the upper, right, hindmost corner of the diagram, the more the student teacher’s beliefs fall in line with modern educational theory.

Freshman student teachers of chemistry tend to bring more teacher-centered, content-structure and transmission-oriented beliefs about teaching and learning into their training. A majority of the collected data appears in the lower, left, frontal part of the diagram. Only a very few of these student teachers appear anywhere near the upper, right, back part of the diagram. Contrary to this result, most of the student teachers in the second group have results which are located in the upper, right, back part of the diagram. This indicates beliefs remaining more in line with modern educational theories. The data observed for the third group shows a similar pattern. This last group also favors by the majority student-centered approaches, including ideas stemming from constructivist learning, and an orientation towards scientific literacy objectives. In any case, these beliefs are not as strong pronounced as those held by student teachers in the middle of their university teacher education program.

DISCUSSION

The above results indicate that chemistry student teachers hold very heterogeneous beliefs about themselves as teachers and about teaching and learning when they are asked at different stages of their teacher education program. The data show that freshmen tend to hold quite traditional beliefs about chemistry teaching and learning (Markic & Eilks, 2008). Chemistry student teachers in the middle and those at the end of their university teacher training programs have more modern beliefs when it comes to teaching and learning, which are in line with modern theories of education.

As mentioned at the beginning, there is, of course, no absolute proof that the sample used in this study is representative for all German chemistry student teachers or beyond. However, this subset of student teachers is typical in the German context. Therefore - at least for the German situation - there are no plausible reasons for us to assume that the beliefs among other subsets of German students should differ radically. This is why we have carefully allowed interpretation of the data and discussed the implications which arise under such circumstances.

At the beginning of their university teacher training programs, the student teachers in this study appear to profess beliefs which may stem from their school experiences (see also Calderhead and Robson, 1991). From the start of their tertiary education, students decide exactly how their chosen career should be developed and carried out. Traditionally-held beliefs which depict teacher-centered classrooms, content-structure-oriented objectives and receptive learning do not seem to be a deterrent for students who wish to become chemistry teachers.

Certainly, the fact that this study showed that student teachers` beliefs about teaching and learning develop during their university teacher education programs is a step in the positive direction, especially since these views tend to evolve into more modern beliefs in line with actual educational evidence. It seems likely that university seminars and lecturers, who base their efforts on modern research theories and discuss theoretical aspects of their fields, can and do influence student teachers` belief structure in a more modern direction. Finally, it would appear that tertiary chemistry education has great potential in its continuous efforts to modify student teachers' beliefs about teaching and learning. Although this is good news, teacher education should also promote self-reflection in student teachers, so that they become conscious of their beliefs concerning their future profession (e.g. Schon, 1983).

This study also shows teacher beliefs not only develop from beginning to the middle, but also between the middle and end phases of teacher education, as was seen in this cross-level study. Generally, the beliefs of graduating teacher trainees tend to remain modern; however, they are not quite as modern as those measured in the group halfway through the educational process. The development here shows a retrogressive step and it seems that teaching practice can also influence teachers' beliefs in the other direction. The restrictions represented by everyday school practices, practitioners' colleagues in the school, and in-service training seminars also seem to have influence upon their beliefs. It seems to be a sound conclusion that exposure to the reality of the teaching career moves student teacher beliefs slightly back towards a more traditional style. The question remains as to how much or how little student orientation can or should be applied during teacher training. To prove this hypothesis, further studies are needed, wherein the beliefs of in-service teachers of different ages and levels of work experience can be compared.

ABSTRACT

In this work we analyze the profile of freshmen students at a teacher preparatory course in Chemistry of a Sao Paulo public university and the school trajectory of nine, in order to examine the school route traveled by the students and the strategies employed by their families and themselves along the school route. The analysis of the profile was based on the student's answers to a written questionnaire and the analysis of their personal academic trajectory was based in semi structured interviews conducted by us. The research was supported by Bourdieu's studies, whose theoretical framework allowed us to identify, by their analysis categories *habitus*, cultural capital, social capital, economic capital and strategies, the objective mechanisms that influence the agents practice, behaviors, expectations and styles according to the school universe. The data showed the family participation in agents' school life, through guidelines, investments and examples, besides their influence in the agents routing to the higher education, that happened in a direct way.

Keywords: *school trajectory, chemistry student, education sociology.*

INTRODUCTION

Considering the limits and contributions of Pierre Bourdieu's Sociology of Education, this work is based on Bourdieu's reflections on the relationship between family inheritance (specially the cultural one) and school performance. The relation between school and family has been studied by many researches in the sociology of education area, some of this has been organized and published by Nogueira, Romanelli and Zago (2000).

Through this perspective, the object of this study was to analyze the profile and the trajectories of freshman students from a chemistry teacher preparatory course of a Sao Paulo public university.

For this purpose we considered some categories elaborated by Pierre Bourdieu, necessary for the understanding and uncovering the intricacies of the success or failure of pupils of different fractions of classes. They are: habitus, cultural capital, social capital, economic strategies. In addition to other information such as the level and the cultural environment of students, sibling number, birth order, gender and values that were also related to those categories.

THE THEORY OF PIERRE BOURDIEU

According to Pierre Bourdieu, the tendency of families to invest in the education of their children depends on the relative weight of cultural capital within the families' overall property and ethos. In this context, ethos refers to children's educational future, seen as what is possible for them. In other words, ethos has to do with the objectively determined likelihood of academic success, and it varies in function with the conditions of existence of each group of agents. Groups absorb these possibilities and express them subjectively in the form of desires, prospects, length of formal education, professional choices, and attitudes toward school (BOURDIEU, 1989).

Each family transmits a cultural inheritance to its descendants. This inheritance, which is purely social, consists of the unit's cultural capital and ethos, and it differs from one social class, and sub-class, to another, according to their social milieux. This inheritance can be understood as a set of types of knowledge, awareness, attitudes, interests, aims, information and linguistic codes. On the one hand, ethos, which is the result of a process of appropriation of the likelihood of success in school, defines the relationship of the social agents with cultural capital and with the school. On the other hand, cultural capital directly influences children's success in school. In Bourdieu's conception, inequalities in performance among agents in the educational system are due to the fact that schools, either consciously or unconsciously, demand of all their agents familiarity with the culture and language in order for students to progress without failures or interruptions. To summarize, they demand that agents have prior knowledge of the codes needed to apprehend the dominant culture that the schools are geared to transmit. For them, agents must have a natural and familiar relationship with culture and language, which gives greater emphasis to their relationship with knowledge, than to knowledge itself. This relationship of intimacy with culture and language, which includes verbal proficiency and cultural competence, is related to their modes of learning.

In Bourdieu's conception, this familiarity with culture and language can only be appropriated by the agents in the context of the family environment, through imperceptible learning provided by the families, which are bearers of the culture of the dominant class. He adds that, since this familiarity with the culture is provided through imperceptible learning in the family context, with no methodical effort, the agents are not aware of it and, as a consequence, this knowledge is attributed to individual talent, vocation and innate aptitudes.

In his view, dominant classes and class fractions have the power to impose on schools criteria for evaluation that correspond to their own educational expectations and cultural products (1974). Schools, therefore, through the verdicts (judgments, sanctions, demands, warnings, advice, etc.) of these sectors of society, implicitly value this dominant culture (especially through verbal proficiency and familiarity with knowledge) and demand it from the various agents, which have acquired different cultural inheritances. The farther this inheritance received from the family diverges from the dominant culture, the less "value" it receives in the eyes of the school.

Bourdieu (1989, 1998) also emphasizes that information about the functioning of the educational system and educational institutions, as well as about the professions of broadest social prestige and the paths that lead to them, make up one of the most important and profitable components of cultural capital that fractions of the cultivated class make use of. He also stresses that to obtain, this familiarity with the culture and language through subtle and imperceptible learning often unconsciously imparted by families, cultural practices must occur in the family context. Families must have the will, or the inclination, to consume the cultural goods considered legitimate. They must therefore encourage their descendants to also take on these practices. Cultural property considered legitimate includes "the symbolic property that a social formation chooses as worthy of being held and desired" and represented by means such as books, periodicals, and frequency at theaters and museums, cinema, and so forth.

From Bordieu's perspective there is an intimate link between a family's educational level and its interest in consuming symbolic goods, since, to consume an item of symbolic value (reading, music, etc.), the agent or group of agents must have acquired the instruments of appropriation and they must internalize the codes needed for deciphering them. He also stresses that, to frequent concerts and movies, families must also have accumulated the corresponding economic capital. He also underscores that a family's educational level also determines the importance it gives to such cultural practices, such as intellectual discussions and the age at which their offspring begin to consume such symbolic goods.

From this perspective, it can be said that the history of these agents (their successes, failures, choices of educational institutions, and professional choices) are related, on the one hand, to the cultural capital inherited from the family and, on the other, to the ethos, among other aspects, and to the family's inclination to invest in its children's studies. According to Bourdieu, this cultural inheritance comes from the *habitus*, which is one of his most important concepts. In his view, habitus presupposes past learning, which is at the basis of the structuring of all later learning. It can be defined as:

"systems of durable patterns, structured structures, that are able to function as structuring structures. They act as a generating and structuring principle of the practices and representations, and such representations can be objectively 'regulated' and 'regular.' But they are not the product of obedience to rules that are objectively adapted to their purpose. Nonetheless, one need not suppose any conscious intention of the ends and expressed mastery of the operations needed to attain them. They are collectively orchestrated without being the product of the organizing action of a conductor (BOURDIEU, 1983, p. 60-61).

According to Bourdieu, the material conditions of existence proper to a particular type of milieu, namely, a milieu which is proper to a given social group or class fraction, and their concrete function in the family context, constitute a fundamental type of mediation in the production of the structures of the habitus.

From his point of view, the identity of material conditions of existence that characterize a given group or class fraction tends to produce similar systems of disposition, at least partially, in all the agents that share these same objective structures, and this results in the relative homogeneousness of the habitus. In other words, agents of the same class fraction submitted to the same conditioning and that are therefore placed in an identical objective position, pass through a process of uniformizing the habitus. They are thus distinct from agents that belong to other social groups. According to Bourdieu, this relative homogeneousness of the habitus is at the basis of the objective harmonization of the practices of all the members. They belong to a given social group, a factor that provides them with a regularity and an objectivity that align their actions without appealing to explicit norms or rules established by the social group or class fraction. In this sense, the habitus serves as the unifying principle of the actions, or practices, of the agents involved.

As Bourdieu (1983) explains, the habitus is the universalizing mediation that makes practices be seen as "sensible," "reasonable" and objectively orchestrated without there being explicit reasons for this and without a significant intention of a singular agent. From this perspective, it can be said that an agent's past persists in the present. The habitus deposited in each agent, within family relationships, brings about analogical transfers of schemes and matrices of perceptions and apprehension. They are at the origin and precede an agent's practice when he or she faces a given situation, thus assuring the presence of past experiences, that are restructured in the here-and-now.

In Bourdieu's conception, the habitus is a system of dispositions "strongly reinforced with regulated improvisations." In other words, the habitus, understood as "analogical transfers of schemes," lets agents behave in very different ways toward new experiences. But this behavior does not arise as unpredictable or unforeseen because the habitus acquired in past experiences is always the basic principle and support. Therefore, such behavior, as a tendency, is recognizable and predictable by all the agents that have acquired the same habitus under the same conditions.

From what was discussed above it can be said that the habitus is "a system of dispositions" acquired in a given family milieu and under certain objective conditions. Its product is not only the cultural capital of the family and its progenitors, but also its actions and practices, consciously or unconsciously organized in common to function as strategies of reproduction. At their final level, such strategies are aimed at maintaining or improving the position of a given social group in the structure of classes. Since the strategies have the habitus as their unifying principle, they are objectively harmonized to serve that purpose.

At this point, the importance of the relative value of the cultural capital of specific families might be brought in as examples. These families are necessarily part of a given class fraction and their importance is related to the structure and volume of their goods.

Bourdieu (1974) cites cases where the educational system is seen as the only means for social ascension. Specifically, he is referring to children of the teaching fraction of the middle class and, especially, young people from the working and middle classes who readily adhere to the importance of education. They expect everything from the school and depend on it, often making up for the privation of cultural capital by developing an intense desire to acquire culture. The results presented by Nogueira, Romanelli and Zago (2000) that analyzed scholar trajectories from popular and medium classes confirm these cases.

METHODOLOGY

The academic histories of students in the undergraduate area of the Institute of Chemistry were studied through semi-structured interviews. To define those students to be interviewed, we made contact with classes in the first year of the teacher-training course (licentiate)[16] in chemistry. The first contact was with a teacher responsible for one of the subjects studied by the group and, after obtaining authorization from the teacher, we contacted the students themselves. At the first meeting we introduced ourselves and briefly described our research project. We then asked the students to fill out a short anonymous socio-economic questionnaire. The last item on the questionnaire asked the name and basic information (email and phone number) for contacting the students who were interested in taking part in interviews about their academic histories. We then collected the questionnaires, classified the students to be interviewed and scheduled sessions with them. At the beginning of the interviews the students were informed as to the topics to be discussed and were asked to fill out a declaration of informed consent. The interviews were conducted according to a semi-structured model, where we defined topics the students had written about on the questionnaires. Further questions were then asked in order to complement the information they had already provided. As was expected, the students added further topics and provided facts about their lives which we had not specifically requested.

16 The technical term “licentiate” (*licenciatura* in Portuguese) is used here as synonymous with "teacher-training course." It confers a degree which gives graduates the legal right to teach the subject or subjects (major or minor) they have studied in university. In contrast, the bachelor's degree is geared to preparation to practice the corresponding profession.

The topics and sub-topics defined for the interviews were: 1) family: the students were asked to describe their level of education and the economic and social situation of their parents, siblings, uncles, aunts, cousins and grandparents; 2) school life (elementary and high school): they were asked about the ages at which they studied in the different grades, the type of school, and the relationships they developed with their teachers and classmates (this point included their academic attainments and to what degree their families had participated in their school life; 3) higher learning: in this item the students stated whether they had had to take crash courses after high school to better prepare for university entrance exams, at what age they began university, how they chose their undergraduate courses, how their families saw these choices, and how they are performing academically in university now; 4) cultural practices: the students were also asked about their facility with foreign languages, their reading habits, whether they played any musical instrument, whether they played any sports, whether they traveled or went to clubs, bookstores, libraries, museums, shows, etc.

STUDENTS’ PROFILE

As we discussed, in order to analyse and determine the student’s profile short questionnaires were distributed in class for freshmen students from a chemistry teacher preparatory course to which all present students responded in writing and anonymously. Questions were the following: What is your gender? And your date of birth? What is the district / city where you live? What's your dad’s profession? What is the profession of your mother? What is your income? In which fraction of class would you situate your family? What is the level of instruction of your father? And your mother? Do you work? What did you do? Do you have a scholarship?

The analysis of the questionnaires distributed to all students of the course allowed us to determine a general profile of the class. There were 35 students that answered the questionnaire. We realized that the majority of students were female (77%), and their average age is 19,8 years old, considering that it varies from 17 to 23 years old. The chemistry teacher preparatory course is offered in an inland city in the state of Sao Paulo, so a greater part of the students (43%) came from other cities, most of which are in the Sao Paulo’s inland, and now live in the city where the course is offered. Another part of the students live with the family in the city of the course (37%) and some in surrounding cities (20%). The family monthly income of students varies from 300 to 4500 USD, but most lie in the range from 1200 to 1500 USD and considered themselves as part of the middle class. The educational level of their fathers and mothers were in most part high school education and higher education. The father’s professions were in most part bank managers, salesman, managers, freelancers, entrepreneurs, among others. And most of the mothers were housewives, teachers, seamstresses, secretaries, and others. From the total number of students that responded, only 6 (17%) work and 18 (51,4%) have a scholarship.

Fiamengue (2002) has also analyzed the profile from the students of the same public university, including the chemistry students, and their results are consistent with the data we’re presenting in this work.

STUDENTS' ACADEMIC HISTORIES

Among the 35 students analyzed in this study, semi-structured interviews were conducted with nine of them (five females). After transcription of these interviews we’ve done a preliminary and qualitative analysis of the data, so certain elements common to the personal academic histories of many of the students could be seen. We considered not only the frequency of these elements or themes, but also its occurrence in the same interview. Our concern wasn’t just to characterize that population of students, which we have already done by the questionnaires analyses presented above. After the determination of these themes we also decided by their relevance according to Bourdieu's theory, then we returned to the interviews and analyze it again. In this text we present these elements and briefly discussed them below. In terms of the period before entering university, we emphasize the following aspects, which will be discussed below: efforts exerted and investment in studies; follow-up on school life by the family; the school aimed at a better future; examples of academic success among older family members; "financial sponsors" in the family; and the role of religion, athletics and music.

The students' accounts of life at school indicated how much effort they had exerted in their courses, especially as they neared the time to face university entrance examinations. They also described the financial investment their families had made in their education. Most of the students (six of the nine) had attended private schools, at least during the final years of high school, as such institutions are considered better than public schools. Besides these direct investments, other strategies were also mentioned that indicated the importance families gave to studies. One example was the case of the Student I (female) whose mother had given her a small sum of money for every book she read, in order to encourage the girl to develop a taste for reading. Another example:

"My father never made us work. He paid tuition at private schools, today I can see this, so I think that the very least I could have done was to get into university right after graduating from high school. [...] But at the time the only thing I was really interested in was dating, and I wanted to study at [a local university] because it was near home. I remember my father wouldn't let me go there. He said 'No. I'll pay for one year of a preparatory course for entrance exams so you can get into a better university, but no more going out during the week. You're going to study and on the weekends you can go out. But I want to see you study because I paid for a private school and even so you didn't get into university. So you have one more year.' And I realized I had better make the best of it." (Student C - female)

We also noted that all families exercised some degree of monitoring of the student's academic lives, either by merely going to parents' meetings and checking report cards or, more closely, such as by checking notebooks and homework, giving "quickie oral tests" at home, and giving dictation, these practices were more common in the first years of education.

"My mother would correct my homework, erase things and tear out pages in my notebooks that were wrong. [...] She would check everything. She worked during the day but at night she kept after me. [...] She always wanted to see my notebook. The worst thing was when I had to show her my notebook because she would tear out whatever was wrong and make me do it again. I would cry and I had to do it all over. Wow! [...] I didn't like it. [...] My parents always went to meetings at school. [...] I was never a top student. I was always average. [...] My mother [...] would swear at me and say, 'You never study! You're an idiot.' You know, that kind of mother, and they leave scars. I still remember all that. Wow! She would fight with me all the time." (Student E - female)

In other words, the families were concerned with school work, an attitude that is reflected in these practices and in the discourse about the importance of a university education in order for the students to have a "better future." For most of them this discourse seemed to have a greater effect when it was accompanied by positive examples, such as there being at least one family member who had finished university and who had thus shown the student a possible path in life that included interesting prospects. In seven families only older siblings, cousins or uncles and aunts had gone to university, but these examples proved to be significant for the students. In the other two cases almost all the members of the family had gone to university and the students faced that possibility as something natural.

"I think I'll make it OK. A lot of people have changed their opinions about me. That's what's good about studying, about achieving, overcoming obstacles. [...] You don't have to prove anything to other people, but you do end up showing them you can do it. Every day my brother [who has a teaching degree in chemistry] moves ahead a little bit at the factory, and there are people who just

want to step on him. I can see that. He tells me about it and it's cool if you can prove your ability and show that you're competent and that you have succeeded. Today I see that if you study you'll get ahead. Nothing's impossible. I never imagined I'd be studying here at Unesp or any other university and here I am. And I got accepted into São Carlos and Fatec, too. I think that if you really study, you can get ahead." (Student D - male)

Concern with schooling can also be seen beyond the nuclear family. Two students told about uncles, aunts and grandparents who paid the tuition for their courses or private schools, which we consider a type of "financial sponsorship."

One of the aspects that came up in four different interviews was the student's connection with the Catholic Church, either through regular attendance and participation in religious groups or through the option of the students to study at Catholic schools. This contact stood out because it apparently brought about a closer relationship with the surrounding culture.

"Yeah. I participate in a youth group. I'm one of the coordinators and so, apart from my classes and course, this is my main interest. [...] So I always have something to do. [...] Since the beginning of 2005 [...] I've taken part in the group and this has helped me be a person, how to be a person. I learned about the paths you shouldn't take and the paths you should take, so I'm sure that this has been an enormous help to me." (Student H - male)

We also saw how often sports were mentioned in the interviews (four of the nine). The practice of sports is encouraged by parents, not as an occupation but as an activity that provides students with discipline, health and responsibility and often improves their performance at school.

"I started playing basketball in the seventh grade. [...] It took up a lot of time and [...] sometimes I'd get up at five in the morning and get home at ten at night. So I spent a lot of time away from home. [...] I kept this up until I was a sophomore in high school and I was used to a long day of activities. [...] Even today I tell my mother that basketball gave me discipline [...] because now I can spend long periods of time at things because there were schedules I had to obey. So I think that's how it gave me a lot of discipline. [...] Today I can sit down and study for hours on end." (Student F - female)

Several aspects concerning entrance to the university and the first year of study will be discussed here. The most important are the following: information about the educational system, difficulties to overcome in entering the various courses, general and specific problems in staying in the course, and compensations, opportunities and recognition of the institution.

Most of the students interviewed (six of the nine) were considered good or excellent students during elementary and high school, but some had to struggle to get into a public university. This meant that almost all of them (eight students) found it necessary to take a course to prepare them for the university entrance exams, sometimes for over a year. From the students' accounts we gleaned the impression that one outstanding feature of admission to university was not the amount of time the students dedicated to their studies or the type of course they took, but rather the information they had about the educational system itself. For example, students who were already aware of the profile of the course and entrance examination for the Institute of Chemistry knew that the area for teacher training (licentiate) had fewer candidates than the bachelor's course. It therefore gave them better chances of entering, even though the two courses eventually conferred the same professional rights as defined by the State Chemistry Board. Five students took the test for the bachelor's course and failed after a whole year of preparation. But in the meantime they had discovered about the differences and equivalence between a teacher-training degree and a bachelor's degree, and were able to be admitted to the teacher-training option. The other two took the exam for teacher training the first time around, and were accepted.

"In my senior year I found out that the educational philosophy of the people giving preparation courses for entrance exams was different and that it would be better to take the course I was really interested in, which was chemistry. I took the exam for chemistry at all the universities that have this course [...] and I took the exam for teacher training in chemistry here, too. [...] Actually, the area I'm most interested in is biochemistry, but there is no such course in Brazil. [...] I also knew that teacher training was geared more to giving classes, while the bachelor's course was more for industrial and research positions. But the course here has prestige and I said to myself, 'I'm going to get a teaching degree there since there is less competition.' So I opted for the course here because I knew it would give me the same professional qualifications as a bachelor's degree. So it's a teacher-training course that is not focused just on education." (Student G - male)

In this same aspect the researchers noted another factor during four interviews, namely, that the course in chemistry, especially the teacher-training course, was not always the students' first option. Some would have preferred more competitive courses such as engineering or pharmacy, and some wanted to take courses their families did not approve of, such as music or art, because of their limited professional perspectives.

"At first I wanted take dancing, but I got no backing at all, from anybody. My mother kept saying that there wasn't much future in dancing, especially here in Brazil, a country that doesn't give much value to the fine arts. [...] She was thinking about what I would do after I graduated, you know, [...] like open a dancing school and have to get by on fees paid by students. It's not easy. She kept saying 'forget it' and I kept on trying, but I finally gave up." (Student A - female)

In spite of this, we could perceive that very few students think about giving up on their chemistry course. They basically say, "I'm not going to give up after all the trouble I had to get in." In this regard, they try to "compensate" at the Institute of Chemistry itself. For example, some of those who wanted to study pharmacy took training programs in the area of biochemistry; some who would have preferred engineering made contact with teachers involved in technological projects; and others yet, who were more interested in the arts, are involved in drama activities and other such options.

"I have a PAE-1-type scholarship [...] so my project is to write a report at the senior high school level so I can learn how to write reports. I could choose any topic I wanted in the area of biotechnology, so I decided to write something about energy production based on biomass and now I'm working on it, you know? [...] It's interesting because for a while I wanted to take aeronautic engineering but [my scholarship advisor] didn't even know about my interest in engineering. He said there were lots of possibilities in the area of chemistry, even if I took the teacher-training course. [...] A secretary here at the institute said there are lots of job opportunities. I told her I wanted to study space sciences [...] and she said 'Oh, wow, who's to say that there are no chemists at Nasa?' And there are! So I thought 'that's cool, isn't it? It's a possibility.'" (Student F - female)

The search for training programs in "Introduction to Science," or for extension projects, is not always directly related to the attempt to "compensate." It often has to do with the idea that the student should "make the best of every opportunity" the institution offers.

"When I first started here I met a guy older than me [who helped me out]. [...] When I chose chemistry I already knew all about [the courses]. I knew that a teacher-training degree from UNESP carries weight and I knew you could take different courses and get both [teaching degree and a bachelor's degree]. [...] When I came to register I met this guy [...] and he told me about the Science Center. He asked me if I wanted to go over there. They have monitors, a physics lab and a chemistry lab □ ' But I said I didn't have enough schooling for that and he said, 'don't worry; they give you the training you need.' So I took an entrance test and passed it, and even got a grant, [...] (because I needed some sort of help just to get by). I knew they gave out grants at the University in Campinas (UNICAMP) but I didn't know they gave them here, too. [...] I wanted to teach and after I started

studying at the Science Center I wanted to teach even more. So I said to myself, 'This is exactly what I want.' I had thought about transferring to Unicamp, but I decided to stay here."' (Student B - male)

We feel that this also reflects the value that students give to studying, to the Institute of Chemistry and to UNESP. During the interviews all students indicated that they feel proud of being part of such a well-known institution. But something else seems to tie the teacher-training students to the institution. They consider the school an extension of their own families. The students interviewed seem to associate the opportunities the institution offers, and the encouragement they receive from their teachers and advisers, to the stimulus they received earlier from their families. This can be seen in one specific detail. All complained about numerous subjects in the undergraduate courses they took. For example, they complained that the courses were too theoretical and showed very little or no practical applications, or they mentioned great difficulties in subjects such as calculus and physics, since they were not familiar with the specific codes of these areas. But the complaints were presented as inevitable or temporary and the students feel they will be forgotten as soon as they are overcome, somewhat like the way people forget about the differences and adversities that families go through.

"Adaptation was a little difficult. [...] Academic work goes at a different pace. It's not the same as at a preparation course for entrance exams. That kind of course is easy. [...] But not here. Here it's one book a semester. In calculus, for example, [...] I thought it would be easy. [...] I had no idea it was so hard. You know. Like having to be poring over books until 2 a.m. and then having to get up at 6:00 to sit down and study some more. I can't do that yet, study for ten hours straight, but I can go eight. At least now I can. [...] I don't get as distracted as I used to. [...] It'll take some time. This first year was a period of adaptation and that's why I don't worry too much about [having failed in several subjects and having to repeat the year]. Did I study? Yes! Did I study enough? No, I didn't! I didn't know enough. I have a problem of not having a good basis [from primary and high school]. [...] I want to teach, I really do, but I have to know what I'm talking about and I can't be bounced ahead in school. Anyway, they don't do that here. If you get a 1, it's a 1, so I don't mind doing the year again. Some people get desperate. So I have to take Calculus 1 twice? Yes, I have to do it twice, but I'm going to learn Calculus 1. I already learned something, but not enough, you know." (Student B - male)

"It was really hard. The first week I liked everybody [...] and my parents did too. I got to know the whole school and [...] I liked the people there. They were all so welcoming. [...] The students, everybody was nice. [...] Then classes started and I started to have trouble. Calculus was especially hard.[...] I failed in one subject and I'm taking the make-up tests now. [...] I'm doing badly in Calculus 2, too, [...] since it's new for me and I have to learn a lot in a short period of time. It's really hard. I don't know. I don't feel like sitting down and studying. [...] I don't know if it's because of the course [...]. I don't give up easily. I think I'll just keep going as far as I can. [...] There's nothing else I'd like to do. [...] If I go on to another course, my family will, you know. [...] It's really the family factor. [...] I like chemistry. In fact, I love chemistry. The first year is hard in any case, right? You have to adapt. [...] That's everything! It's a different pace of study. Everything is different. [...] There aren't many practical classes; everything is classwork, so I'm hoping. Everybody says the first year is the hardest." (Student A - female)

CONCLUSIONS

Our analysis would seem to show this relationship between the wealth of agents and their school history, as was the objective of this study. We have tried to highlight certain features in the students' accounts during their interviews. We noted, for example, that it is part of the *habitus* of these families to participate, at home, in the students' academic life by motivating them to study and, in general, to attain some success at school. In terms of school and studies, another strategy used by this *class fraction* is to have sent their children to private high schools whenever possible. On the symbolic level, we note that families in this social category see the university as having the role of training the agents professionally, since a university degree is virtually seen as a "regular part of life." It is seen as a way (a maintenance strategy) for this social stratum to continue in the social structure. It's important to analyze these facts through the *habitus* concept which links the social and the individual context. So, we considered that these students were surrounded by a social and familiar mileux that valorizes the studies and the university, for the reasons we have already discussed, but for some psychological and individual reason, that were not discussed in this work, these values were absorbed by the students and constitutes their *habitus*, as we can see through their statements.

In general, we observed that it seems that the students from this course presents three main characteristics in their way to became a graduate student at a teacher preparatory course in chemistry from this specific public university: they face a long preparation time before entering the course; they give up on their initial professional dreams; and they are supported by their families during all this process.

We believe that although their families considered that the university was an obligatory step in their preparation for professional life, they didn't know the "codes" that rule this educational field. It sometimes leads to a longer preparation time before entering the university, that was reduced in some cases by the social capital that the students had. Even without this knowledge the families were always supporting the student's path, which help them to achieve their goals. The data showed that the families participate in the agents' academic life by setting up guidelines, investing and giving good example, besides their earlier and direct influence in routing the agents toward higher education. But, this lack of knowledge about the higher education that the students and their families presents also led them to "impossible" dreams, like being musicians or engineer without the appropriate preparation to these professions. Or even led them to choose bachelor's course, that gave less chances of entering then the teacher training course, even though the two courses eventually conferred the same professional rights as defined by the State Chemistry Board. Then, some students took the test for the bachelor's course and failed after a whole year of preparation. After failing, these students chose a profession and a course adapted to their medium knowledge obtained by a huge effort, this kind of choice regulated by the social milieu has been described by Bourdieu as the "causality of the probable".

We also realize that many students presents difficulties to accompany the course. We believe that some of these difficulties might be related to the long preparation time they took before entering, which means that maybe these students entered even without having the minimum knowledge demanded by the course, or that the course is not adapted to the characteristics of the students that entered – and so it had to support the students, continuing that preparation time they had before entering the university.

Another characteristic that stands out is the students' determination to continue on in their course despite these difficulties they encounter along the way. Certainly one important contribution to this determination is related to their personal and family efforts and investments made in preparation for and entrance into the university. The prestige of the institution is also part of this effort, but we believe that the opportunity to compensate for problems that come up and the interest of the university teachers toward the students also contributes to support them in the choices they have made.

In our opinion, the information obtained in this study is significant and we feel it can be used by the institution itself in its plans to monitor students with different types of cultural capital, backgrounds and profiles. This type of activity on the part of the university would be aimed at keeping the students in university and at restructuring their *habitus*. We perceive the institution's success in providing the students with different activities and we feel that these actions should be maintained and even expanded.

A TAXONOMY OF INQUIRY ACTIVITIES

Daniel Z. Meyer

Illinois Institute of Technology

meyerd@iit.edu

ABSTRACT

Inquiry has become the central focus of science education. Much of the work looking at the specific structure of inquiry activities has either been general goals or rubrics for assessing the degree of inquiry learning. This paper is intended to illuminate the means for achieving those goals and levels by articulating a taxonomy of different structures for inquiry activities.

Keywords: *inquiry, curriculum.*

INTRODUCTION

Inquiry has become the central focus of science education, and prompted several veins of scholarly work to support this effort. However, we are concerned that there is a gap. Work looking into the structural details of inquiry have occupied the ends of a spectrum from general to specific. On one end, we have articulations of goals or rubrics for assessing existing activities (Breerer & Bodzin, 2003; Herron, 1971; Wheeler, 2000). On the other end, we have specific activities or rich descriptions of inquiry in practice (Minstrell & van Zee, 2000; National Research Council, 2000).

This paper is part of an effort to fill in the research base. By identifying structures for inquiry that are more general than individual activities, but define means to achieving the standard characterizations of inquiry, we provide guidance to teachers and other instructional planners. Here, we share a categorization of inquiry activities.

NEEDS OF INQUIRY

The inquiry addendum to the American National Science Education Standards (National Research Council, 2000) identifies the following as the essential features of classroom inquiry: 1) Learner engages in scientifically oriented questions; 2) Learner gives priority to evidence in responding to questions; 3) Learner formulates explanations from evidence; 4) Learner connects explanation to scientific knowledge; 5) Learner communicates and justifies explanations.

This defines a good target, but we wish to address the problem of how to create the conditions in the classroom where these learner activities can happen. We have identified two specific hurdles that must be overcome (Author, in review). First, asking and appreciating scientific questions requires working from some base context. While attention to the prior knowledge of students is certainly critical to any teaching, engaging in inquiry requires a meaningful reference point for participants. Therefore there is the Getting-on-Board Problem of how to orient students to a particular scientific context. This is a problem that is overcome in the world of practicing scientists through participation by new practitioners in the research programs of more senior practitioners. But in precollege and even college academic settings, this cross generational engagement is extremely difficult and rare. Second, formulating, communicating and justifying explanations requires that those explanations not be trivial. There must be something to have contention over. Therefore, there is a Variability Problem of insuring some degree of complexity in the data students will work with. Whereas, the work of practicing scientists is by definition in the areas of dispute, the focus of precollege science education is generally over very well established content. Overcoming the Variability Problem is not a matter of simply shifting topic area, however. There are often technical and cognitive barriers to facilitating student access to those areas that have more potential for contention.

Two key decisions for the designers of inquiry activities are the choice of task to give students and the choice of data with which they will work. Each choice is a balancing act. If a task is too prescribed, the activity becomes a cookbook lab. If the task is too open, students may not be able to even begin. If the data set is to simple, the activity becomes a confirmation lab, with nothing to contest. If the data set is two complex, it may be beyond students technical or conceptual abilities to work with.

TAXONOMY

To date we have identified six categories of inquiry activities. Each provides a different structure for overcoming the two problems in designing inquiry activities described above. The first three we refer to as heuristic categories because their structure not only describes their nature but also provides guidance for forming original activities. The other three depend more on the intrinsic appeal of the situation they create. The first two come out of specific past curriculum development projects. The remaining categories have been formed by considering other inquiry activities that do not correlate to the original two categories.

PROTOCOLS

A *protocol* is a well-defined procedure for collecting data. In terms of definition and clarity of steps, it is quite similar to a traditional cookbook lab. However, it is portrayed as being clearly just a tool – as opposed to the entirety of the lab experience. More importantly, a protocol can be applied to a wide variety of situations – not just the situation in which it is introduced and learned. (Hence some cookbook labs can be adapted to form protocols, but others cannot.) Once the student learns the protocol in an initial circumstance, they can then apply it to further research. This research can be more varied and more student directed.

The prototypical case of a protocol is the lettuce seed bioassay (Trautmann, 2001). Students are given fairly clear directions for producing a serial dilution of a salt solution, setting up a bioassay using lettuce seeds, and evaluating the results. Once they have had that experience, they can now engage in further, more varied research: other concentration ranges, other toxins, and even other biological indicators. At the most sophisticated end of the spectrum, the bioassay can become a moderate piece in a larger extensive research endeavor.

Another example of a protocol is the Watershed Habitat Evaluation and Biotic Integrity Protocol (WHEBIP) (Carlsen & Trautmann, 2004). This protocol was created to allow scientists to use models to predict aquatic biodiversity in watersheds. In this protocol, stream integrity ratings are assigned using land use criteria and can be accomplished using aerial photographs or remote sensing without requiring ground truthing (although in some instances, it is appropriate). Ratings are based on information students assess including size of riparian belt, type of land use near stream, gradient, pollution, and conservation activity. Students can use this protocol to make a preliminary assessment of a habitat and if desirable, make comparisons to data gleaned from ground truthing. This tool enables students to obtain data for one or multiple sites within watersheds or comparative studies between watersheds, and to make recommendations for remediation.

Learning a protocol is not just a question of now having a new technical skill. It overcomes the Getting-on-Board problem by introducing student to an entire way of looking at the natural world. The data set they produce in the initial learning round is also significant. It can be an indicator for what merits investigation next, just as with science at large. Hence the student has been brought on board the knowledge development cycle.

DESIGN CHALLENGES

Design Challenges are centered around an explicit production task. Often the task will motivate the practical need to acquire certain knowledge bases. Sometimes inquiry designers will use a jigsaw arrangement, where students are divided into specialty groups to learn one of those knowledge bases, then rearranged into design teams made up of representatives of each specialty group.

Forming the charge to the students is the critical and creative focal point of designing Design Challenges. Doing this well can determine if the balancing acts have been achieved. A way of framing the problem is to give students a question that is understood as a question, but not as a solution. A question for which students already have a single, preconceived solution will not generate the argument opportunity necessary for inquiry. At the other end of the spectrum, a task for which students have no conception or ability to proceed is equally unfruitful. But it should also be noted that there is another way in which Design Challenges can be too open-ended. Consider the challenge for middle school students "design and build a paper airplane." This avoids both of the problems noted so far: students understand what a paper airplane is and have the intellectual and material resources to do so; and they are likely to propose multiple solutions. But then what? The litmus test we put out above requires *warrant*-based arguments – essentially saying "this is better because of such and such". As stated, this design challenge does not include any means to defend why one design is better than another. The challenge is *too* open – not in term of students' cognitive or technical ability to achieve it, but in terms of it being a meaningful competition. Design Challenges must include pressures that require student designers to make judgments and back up those judgments with arguments.

While producing a tangible object is perhaps the more common instance of design challenges, we should not limit our view in this manner. The common element is producing a product. Consider the following example (Author, 2003). Students are given a scenario of a local community that is experiencing pollution in a local waterway. The students are divided into different constituency groups: farmers, homeowners, industry and municipal authorities. They are given a variety of information resources – some common and some specific. They then have a variety of meetings – some in homogenous groups and some in heterogeneous groups. The task and final outcome of those meetings is to develop a restoration plan.

Design challenges can also result in tangible products. One example of this is the stormwater treatment design challenge (Carlsen & Trautmann, 2004). This activity models how cities develop systems for collecting and draining runoff from storms. Using simple materials such as plastic soda bottles, tape, coffee filters, cat litter, sand, gravel, and plastic tubing, students are given the task of creating a filtering system that can handle a simulated storm event over a relative period of time. They need to take into account the various types of substances (such as chemicals, dirt, oils, etc) found in runoff, the volume of the storm event, the time between events and the extent to which the stormwater needs to be filtered. Like engineers in the real world, they are also constrained by materials, guidelines, budget, time and design. From a curriculum design point of view, the specifics of the design constraints (size, materials, etc.), evaluation measures (ph, DO, etc.) and simulated run off (particulate matter, oil, etc) will be what determine how the balancing acts have been achieved.

Just making something, however, does not make an effective design challenge. It can just be the Design Challenge equivalent of a cookbook lab. Consider the common example of students in physics classes designing roller coaster rides. The details of the assignment are crucial in determining whether this is an effective Design Challenge. Often, students design the ride in a fairly arbitrary way, and then post facto apply physics principles to determine elements like speed. The laws of physics do provide limitations on the design (e.g. a hill can not be too high that a car will not have the energy to reach the top). But there are not competing constraints that provide for points of debate. Once a student stays within the bounds of physics, any choice is an arbitrary preference, and hence, there is no opportunity for argumentation.[17] This illustrates how the details of an assignment can have a profound effect.

PRODUCT TESTING

Product Testing activities present students with a question of the form “which is the best X”. This requires students to devise and implement ways to consistently compare items, and often to quantify those comparisons. This means recreating a phenomena in a controlled, reproducible and measurable manner.

This challenge often breaks down into three parts. First, students must determine what the desired attributes of the product are. Second, students must devise ways of consistently testing those attributes. Lastly, they must determine a way of combining the results.

A simple example of a Product Testing would be determining the best paper towel. Students would first have to design what attributes effect the desirability of a towel. This might include absorption, strength and price. Then they need to devise ways to test and quantify those attributes. And lastly, given the results of that testing, they must integrate the results to choose a best paper towel. Product Testing therefore overcomes the Variability Problem with three separate opportunities for contention.

Overcoming the Getting-on-Board Problem is often helped through the use of a familiar phenomena (such as paper towel use). In addition, it is significant to note that students are not creating the products, but rather assessing them. In a sense, the Product Testing model is the inverse of the Protocol and Design Challenge models: rather than being giving a

[17] We should note that we are not arguing that such an activity is not worthwhile, but simple that it does not work as an effective design challenge.

protocol and asked to find opportunities to use them, students are given the objects and need to create the protocols to apply; rather than creating a product to meet certain criteria, students are asked to create the criteria to assess given products.

BLACK BOXES

Black Boxes challenge students to determine the nature of things hidden from view. They require students form logical arguments since they must reach conclusions without direct observations. Hence, overcoming the Variability Problem is at the heart of their nature.

Depending on their nature and context, Black Boxes can be used to highlight various concepts. The most common and broad is illustrating the difference between observation and inference. For example, the simplest Black Box activity is a literal box containing various objects, where students are challenged to determine the nature of the contents without opening the box. This also demonstrates how Black Box activities must not simply be puzzles, with one acceptable solution. Rather, the fact that one cannot directly examine the contents – its black box quality – means that the argument about the conclusion is even more essential than the conclusion itself.

Black Boxes can also be used to make more specific connections to atomic theory. They illustrate the ability to reach conclusions despite a lack of direct observation. For example, students can be challenged to determine the size and shape of objects hidden form view with marbles or other small balls, thus being analogous to scattering experiments. Other Black Boxes can be devised where some observations also change the object, hence simulating the Heisenberg Uncertainly Principle.

Black Boxes can also be used to illustrate modeling as a form of scientific inquiry. The Mystery Tubes exercise presents students with a tube containing various ropes. Pulling on a rope may (or may not) effect the other ropes. Students are challenged to create a tube of their own that mimics the behavior of the target tube, hence modeling the phenomena.

DISCREPANT PHENOMENON

Discrepant Phenomenon activities center around an distinct, non-intuitive, and often impressive, event, and naturally poses to students the question “what is going on?”.

The Ammonia Fountain (Shakhashiri, 1989) is an example of the Discrepant Phenomenon Model. Here, students see water rise up a tube and turn into a pink fountain. The cause challenges students’ common conceptions of suction. This also illustrates how Discrepant Phenomenon activities have a strong content connection.

The non-intuitive aspect is crucial for overcoming both the Getting-on-Board and Variability Problems. It helps make the question to students both meaningful and non-trivial. And it provides opportunities for multiple positions. However, an effective activity requires that the students experience the phenomena as discrepant. Whether a particular phenomenon has that discrepant quality is dependant on the context and the students. What is obviously problematic for one set of students might not be for another.

Many Discrepant Phenomenon Activities are done as a teacher led demonstration, for technical or safety reasons. However, they also illustrate how an otherwise teacher centered activity (the teacher is in control and doing the physical work of the activity) can be executed in an inquiry manner. And like the Protocol Model, the Discrepant Phenomenon Model provides a possible opportunity for turning traditional cookbook labs into inquiry activities.

The Discrepant Phenomena model is also a means to take advantage of novel circumstances and “teachable moments”.

INTRINSIC DATA SPACES

Intrinsic Data Spaces immerse students in a data space that inherently implies a question. They have a “sandbox” aspect that allow for easy exploration of the data. These overcome both the Getting-on-Board and Variability problems by presenting a natural puzzle.

An example of the Intrinsic Data Spaces Model is Mystery Bones. Student are presented with cut outs of bone fossils. Arranging the bones into possible animal formations is a natural task. Students can be further challenged to make conclusions the nature of the animal. Hence it should be pointed out that while the Intrinsic Data Spaces Model does depend on the natural draw of the data that does not need to be the full extent of the activity.

Simulated environments would be an important sub-category of Intrinsic Data Space activities. Such computer programs, such as Interactive Physics (Interactive Physics, 2005) or Stella (Stella, 2009) can be effective in allowing students the flexibility and freedom to explore (thus overcoming the Variability Problem) while lowering the technical and cognitive barriers (thus overcoming the Getting-on-Board Problem).

Taxonomical exercises would be another important sub-category of the Intrinsic Data Space Model. Categorization can be a natural routine with a given set of items. This is also a topic that tends to be taught in reverse – starting with categories – giving students the misconceptions that these categories are self evident and unproblematic. But starting without labels – such as giving data tables of a variety of solar system objects without names – can create a meaningful inquiry activity. Effectively overcoming the Variability Problem will depend on the number and range of item, in order to avoid funneling students to a predetermined conclusion.

SUMMARY

These categories are intended to outline different paths to attaining the student experiences seen as essential for scientific inquiry. Their differences should be viewed as an asset, as each has nuances that may be advantages in different pedagogical circumstances. For example, the Protocol and Discrepant Phenomena Models seem better suited to situations that have specific content goals, where as the Design Challenge and Product Testing are well suited where the nature of engineering processes is a learning goal.

While we see these categories as distinct paths to reaching the goals of inquiry, combinations are also possible. A Design Challenge with the ultimate goal of planning a long lasting public monument can begin with a series of Protocols around erosion. The Bioassay Protocols described above can be come a minor part of a Design Challenge to improve storm water filtration. Students can be introduced to the Stella computer modeling environment (Stella, 2009) as a Intrinsic Data Space through a series of mini-Design Challenges. These combinations allow instructional planners to take advantage of the features of the different categories and create a more authentic overall experience.

Lastly, it is important to understand that these categories are tools, not panaceas. Instructional planners must still be conscious and creative about the proper conditions to allow for student inquiry. In particular, achieving the right balance in defining the task and the data that students work with is very particular to both the activity and the audience.

IMPLICATIONS AND FUTURE RESEARCH

In this research, we hope to aid teachers and other instructional planners by both getting more specific about the forms inquiry can take than general goals and descriptions on the one hand, but on the other hand provide a more general framework than specific activities. The categories we have identified here contribute to further defining the problem space of inquiry design.

There are two critical threads of future research. First, it is important to continue challenging the robustness of this taxonomy. This can be done by holding it up to various sets of inquiry activities, and considering how well they are sorted. The result will either be a conformation or expansion of our categories.

Second, an important utility of having such defined categories is that we can then systematically examine and provide guidance on the details of instruction. For example, what are the important features that make a Discrepant Phenomena Activity work? As discusses above, we have begun to do this for the Protocol and Design Challenge Models.

Emeritus Professor

Kobe University, Japan

ABSTRACT

Since the "Science Communication in Theory and Practice" was translated into Japanese and published in 2003, the movement of science communication widely occurred in Japan. However, there is a significant problem in this new movement. We have to accumulate the knowledge as concrete factors of how to establish a maintainable organization of the PAS providers. In this research, based on the case example of the Field Studies Council in Britain, it is considered that the characteristic issues of how the FSC managed its organization successfully as a provider of PAS by historical approach. It is also discussed the fundamental factors of PAS maintainable management based on the case study of FSC operation. As a result, it turned out that the FSC strove to be financial independence in the early period and finally succeeded in the measure aiming at the growth of the organization. In sum, it is recognized that considering a financial aspect can be regarded as a viewpoint of the PAS maintainable organization. While the viewpoint of financial aspect is important to focus on the maintainable organization, it is also required to scrutinize various types of PAS providers as case examples and to obtain practical suggestions about management to maintain PAS organizations and enterprises.

Keywords: *Organization management, informal educational facilities, Public Awareness of Science, the Field Studies Council*

INTRODUCTION

Since the "Science Communication in Theory and Practice (Stocklmayer, S. *et al*, 2001)" was translated into Japanese and published in 2003, the movement of science communication widely occurred in Japan. For example, museums and universities started to hold events explaining the latest science issues for the public people as their own enterprise. As one of the trend of science communication, the National Museum of Nature and Science set up a science communicator training course in 2006 (Ogawa, 2007). As well as this kind of museum enterprise, events of "science cafe" started to at local places. The science cafe is an event to provide a place where scientists and the public people talk together freely about science issues, drinking coffee or tea. It differs from the lecture meeting and academic symposium. By such trends, promotion of PAS is progressing step by step in Japan.

However, there is a significant problem in this new movement. According to Ito (2006), there is little idea how to establish a maintainable organization for the promotion of science. In fact, an organization of the “science cafe Kobe” run in Kobe city, is constituted by volunteer teaching staff members in Kobe University and supported by funds from the governmental auxiliary organization (Ito, 2006). This kind of enterprise may be difficult to carry out continuously, if the members’ motivation falls or funds are turned off. Therefore, not only carrying out events by the volunteer members with funds support, but also establishing a maintainable organization is important to promote PAS for the future. In this regard, we have to accumulate the knowledge as concrete factors of how to establish a maintainable organization of the PAS providers.

THEORY

As regard to the present situation of the PAS enterprise in Japan, it is necessary to research on the factors to investigate how to establish and maintain the organization of a PAS provider. However, in the science education research field, few studies focused on the organizational operation for the promotion of PAS.

While management study is few in science research field, there are substantial examples in art management for the promotion of art. The art management is a research area which discusses techniques for spreading art into society and leading development of art. For example, management of globally famous art institutions, such as the Metropolitan Museum, the British Museum, and the Sydney Opera House, introduced as case examples so far (Caldwell, 2000; Colbert, 2003).

Once, Layton (1984) explained the situation of how science was infiltrated into the society in terms of the establishment process of several associations, such as the Association of Public School Science Masters, the Association of Science Teachers, and the Science Mater’s Association. He mentioned the organization management of policy, human resources, and funds and described how each association was established and grew in the social relationship. However, investigating significant factors to maintain the PAS providers has not progressed to date.

Then, it should be important to make a first step for the PAS management research to obtain some suggestions by the outstanding example as a provider of the PAS enterprise.

PURPOSE OF THE RESEARCH

The purpose of this research is to find out the outstanding example as a provider of PAS enterprise and to extract the element of PAS management. In fact, the organization in overseas was focused on as a case example, since there is few organization in Japan that has been succeeded as a provider of PAS enterprise.

The Field Studies Council (FSC) in Britain is made into the case example in this research. The FSC is a charity organization to provide field study programs with the motto of “bringing environmental understanding to all”. It runs 17 field centers in the UK in 2010 (Field Studies Council, 2010). It was established in 1943 and has provided scientific fieldwork for both children and adults for more than 60 years. Today, the FSC is regarded as a pioneer of delivering academic field studies in Britain. In fact, Dillon *et al.* (2006) described that the FSC is an significant organization of field science provider in the UK. The current characteristics of undertakings and organization management of the council are explained that they correlate both with social education and school education (e.g Miyake, 2003a; 2003b; Baker et al., n.d.; Field, 2002).

This research will consider the characteristic issues of how the FSC managed its organization successfully as a provider of PAS by historical approach. It will be also discussed the fundamental factors of PAS maintainable management based on the case study of FSC operation. Then, finally, an implication for the present PAS enterprises in Japan will be explored.

METHODOLOGY

In order to extract the success elements of the FSC management, and discuss the fundamental factors of PAS management, data collection and research procedure are carried out as follows.

Data Collection

The author collected annual reports, which the FSC published every year since its establishment in 1943. From 2000 to 2005, the author went several times to the FSC head office and field centers, and obtained those annual reports. A total of 61 reports from the 1943 to the 2003 fiscal year were procured. Furthermore, when the author visited the FSC head office, interview about the present organization structure was carried out for the chief executive, Mr. Anthony Thomas.

Procedure

Based on data sources above, the following two issues will be discussed in this research.

1) Considering characteristic issues which encouraged the growth of the FSC

> First, the author divided the historical development process of the FSC into four terms as the dawn period (1943-1955), the construction period (1956-1968), the maintenance period (1969-1987), and the expansion period (1988-2004), and described characteristic issues in each period that encouraged the growth of the FSC (Miyake, 2009).
>
> Then, these characteristic issues are classified with a view of management. The view of management is made into four points as physical resource, financial resource, human resource, and information resource, which are interrupted by the museum management view of Ohori (2001) and Wilson (1989). Among these four resources, information resource includes information technology, networks and communications with other organizations. Therefore, in this study, the information technology is interrupted as intellectual strategy for communication with others.
>
> Based on these procedures, it is considered that how the FSC encouraged to grow as a PAS provider.

2) Investigating fundamental factors of the PAS maintainable management

> It is considered a significant view of PAS management to maintain the organizations, based on the characteristic issues of the FSC management.

RESULT: CHARACTERISTIC ISSUES THAT ENCOUTRAGED THE GROWTH OF THE FSC

The characteristic issues in the four historical period of the FSC are shown in Table 1. In this section, these issues, which are thought to be linked to successful maintenance and expansion of the FSC organization, are summarized in terms of the four management resources; physical resource, financial resource, human resource, and information resource.

Physical resource

First, there are five issues which link to the physical resource.

- Establishment of four field centers by voluntary work of ecologists and educationalists
- Quantitative and qualitative improvement of the field centers
- Establishment of a day center
- Establishment of the new field centers in Northern Ireland and Scotland
- Maintained appropriate learning environment that considers amenities and safety of users

These five issues show that the FSC secured field centers as the base for enterprise. The organization increased the number of centers and strove for the qualitative improvement of them. Even if a financial condition got worse in the construction period, the FSC was maintained all field centers without abandoning.

Financial resource

Second, there are three issues which link to the financial resource.

- Preparing for self-support accounting system
- Transition to the self-support accounting system from the grant-support system, because of the financial cut of the governmental support
- Increase the number of users of field study programs and field centers

It turned out that the FSC took the measure for carrying out financial independent management in the early period. The strategy to increase the number of users seemed to lead financial success of the organization, because the participation fee was the important income source. As a result of shift to the self-support account system from the grant-support system, the FSC had a critical phase to be independent.

Table 1. Characteristic issues through the historical periods of the FSC (Miyake, 2009)

Period	Characteristic issues
Dawn period (1943 - 1955)	1) Establishment of four field centers by voluntary work of ecologists and educationalists 2) Providing field study programs for amateur groups in the field centers' surrounding natural environment 3) Preparing for self-support accounting system
Construction period (1956 - 1968)	1) Quantitive and qualitative improvement of the field centers 2) Providing field studies for the students at secondary educational level 3) Publication of an academic journal: "Field Studies" 4) Transition to a self-supporting system from a grant-supporting system, because of the financial cut of the governmental support 5) Increase the number of users of field study programs and field centers 6) Training of academic staff members 7) Establishment of a research unit
Maintenance period (1969 - 1987)	1) Establishment of a day center 2) Promotion of field studies for the general public 3) Establishment of "units" in field centers 4) Implementation of staff training focusing on users' safety 5) Cooperation with international and domestic organizations
Expansion period (1988 - 2004)	1) Establishment of the new field centers in Northern Ireland and Scotland 2) Maintanance of appropriate learning environment considering amenities and safety of users 3) Providing educational programs for children and students that corresponded to the educational curriculum 4) Providing learning programs for the general public focusing on lifelong learning 5) Composition of the decision-making organization consisted of human resources having experiences in field center management and learning instruction 6) Field center management based on the discretion of the center directors 7) Hiring full-time staff members with professional skill of environmental science issues 8) Divided process development of field study programs 9) Environmental consulting conducted overseas

Human resource

Third, there are four issues which link to the human resource.

- Training of academic staff members
- Implementation of staff training focusing on users' safety
- Composition of the decision-making organization consisted of human resources having experiences in field center management and learning instruction
- Hiring full-time staff members with professional skill of environmental science issues

The FSC employed the persons with professional skill of environmental science issues as full-time staff members, and educated and raised them. The staff members who had on-site experiences in field centers were placed in the central decision-making section of the organization.

Information resource (Intellectual resource)

Finally, there are four issues which link to the information resource.

- Providing field studies for the school students corresponded to the education curriculum
- Providing learning programs for the general public focusing on lifelong learning
- Publication of an academic journal: "Field Studies"
- Environmental consulting conducted overseas

The FSC offered field study programs that followed school curriculum of national education policy. As well as to follow the education policy, it provided field study programs to attract the various interests of people in wide range of age group. Moreover, the FSC forged ahead to overseas through the publishing business and the consultancy business. In other words, the FSC expanded its enterprise as the result of the growth of the organization.

Characteristic issues in the history of the FSC

The characteristic issues, which lead maintainable management of the FSC organization, are shown as follows.

1) The FSC took the measure for financial resource to carry out financial independent management in the early period.

2) The FSC strove to maintain and to be rich in physical resource, without reducing the number of field centers.

3) The FSC employed the persons with professional skill of environmental science issues as full-time staff members, and educated and raised them as human resource.

4) The staff members who had on-site experiences in the FSC's field centers constituted the central decision making organization of the head office.

5) Field study programs follow the education policy as national curriculum and meet the various interest of a wide range age group of people.

6) The FSC advanced to the publishing business and the consultancy business as expansion of the enterprise.

DISCUSSION & CONCLUSION: FUNDAMENTAL FACTORS OF THE PAS MAINTAINABLE MANAGEMENT

In the above section, the characteristic issues that encouraged the growth of the FSC are outlined. This section will discuss the success factor of the FSC as a PAS provider and will suggest fundamental factors of the PAS maintainable management.

Success factor of the FSC as a PAS provider

The FSC was originally established by the voluntary peers of ecologists and educationists, and supported by the governmental funds at first. However, the financial support was cut soon. This would be the first point to become a maintainable organization, because the FSC had a strategy to be an independent organization after the financial crisis.

The outline model of strategy which led the growth of the FSC is shown as Figure1. First, the FSC strove to shift from the grant-support to the self-support accounting system. Then, considering tactics for ensuring income was necessary for the FSC. As one of the tactics, the FSC aimed to improve quality and quantity of the service.

The outline of the improvement are, for example, 1) developing a way of delivering field studies as physical resource, 2) corresponding with national policy as school curriculum and with demands of people as information resource, and 3) training of the staff members and setting on-site experienced persons to the decision making section as human resource.

In this regard, these contents of management resources seemed to lead the expansion of the FSC's enterprise. To sum up, the FSC strove to be financial independence in the early period and finally succeeded in the measure aiming at the growth of the organization.

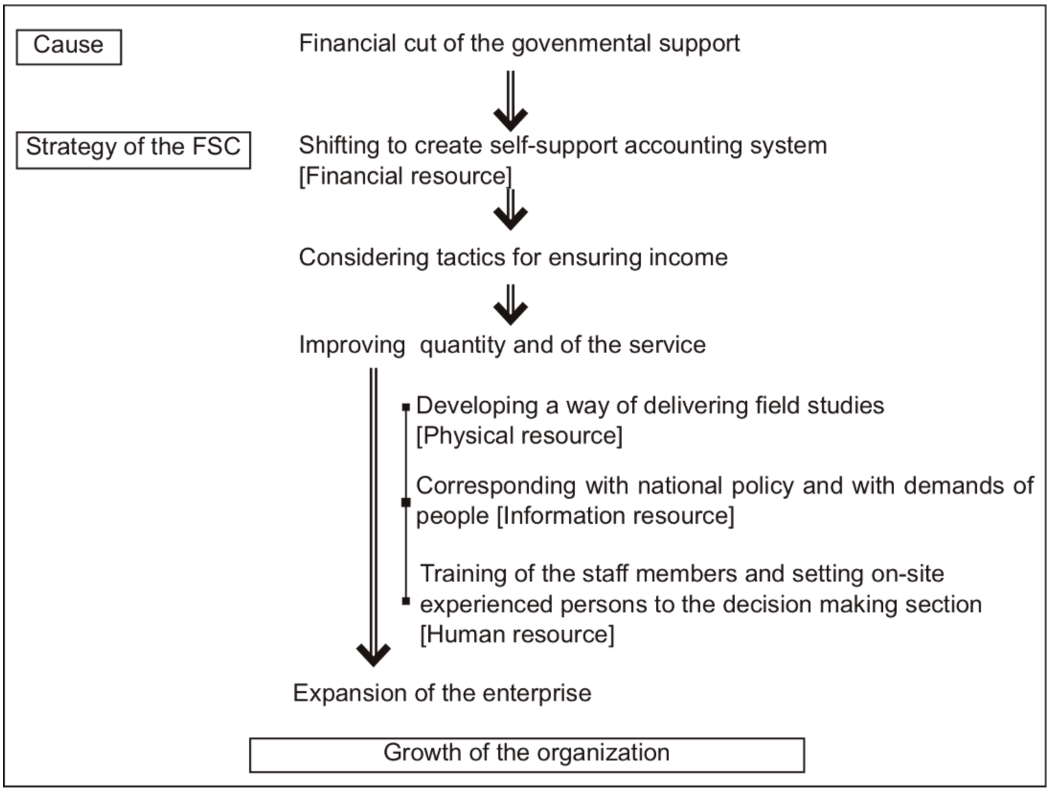

Figure 1. The outline model of strategy leading the growth of the FSC

Implications to the present PAS enterprises in Japan

By the result of historical survey, the present stage of the Japanese PAS enterprises seems to be the same as the early stage of the FSC dawn period. It is because volunteer members carry out the PAS enterprises as their optional work. This is the similar circumstance when the FSC was born at the dawn period in its history.

The difference cannot be compared clearly in the social system of the PAS enterprises between Japan and Britain only by the result of this research. However, if the viewpoint of the PAS organization management proposed by this research and suggestions from previous various research works are considered, implications for the Japanese PAS enterprises would be explored.

In Japan, institutions in the rich natural environment like field centers have been established since 1959 and managed by the national government. Their policy is aiming at planning and carrying out educational programs of outdoor activity through nature for young people (e.g. National Institutions for Youth Education, 2006). Although there is a program to look at flowers and creatures, there is no learning program to promote scientific and ecological understanding of the surrounding natural environment in these institutions. As well as this, there is accommodation to stay in the facilities, however there is no room for science-experiments. In this regard, the infrastructure of the PAS organization, which offers learning programs for natural science, has not been improved yet in Japan. Moreover, the promotion of science awareness to the public people was enforced in 1995 by the Science and Technology Basic Low. After that, the relationship between the driving actors and the target actors in the public of PAS was discussed (e.g. Ogawa, 2006). But the concrete idea of the sustainability of the public community for PAS has not been produced yet. These issues may suggest one of the reasons why the establishment of the PAS organizations in Japan has not be progressed yet.

On the other hand, in Britain, the trend of educational enterprises in terms of ecological and environmental science was set in the 17th century. For example, the Royal Society that is the organization of bearing natural history for people was established in 1660 (Royal Society, 2010; Allen, 1976/1994a). Moreover, Allen (1976/1994b) suggests that delivering outdoor natural science studies were stabilized as a market in the 19th century in Britain. This kind of social situation may promote to establish the pioneering organization like the FSC in the 20th century in the UK. In fact, by the case study of the development of the FSC, it is suggested that the "strategy to be financial independence" seems to lead maintainable growth of the organization. Therefore, it is recognized that considering a financial aspect can be regarded as a viewpoint of the PAS maintainable organization.
To sum up, it is considered that extending a field science study market and financial independent of the PAS groups are inquired to promote PAS as further social movement in Japan. However, the financial issue is not always a main goal for the PAS organizations, because the public facilities do not work only for their profits. There may also be influence of a substantial culture or political issue in the development of the PAS organization. Then, it is required to scrutinize various types of PAS providers as case examples and to obtain practical suggestions about management to maintain PAS organizations and enterprises.

ACKNOWLEDGEMENTS

This research is supported by the Grant-in-Aid for Science Research No. 20240068 from 2008 to 2010 and for the Young Scientists (B) No. 22700795 in 2010 of the Ministry of Education, Culture, Sports and Technology in Japan.

ABSTRACT

It has been established that epistemological barriers play a significant role in effective teaching and learning. The aim of this research is to investigate the impact of African epistemologies, including sociocultural and human values, on learning in the field of biotechnology. The study intends to investigate what epistemological barriers there may be for the teachers and learners in the field of biotechnology at the Universities of the Witwatersrand in South Africa and the University of Namibia in Namibia, with the focus on facilitating capacity development through teaching at the tertiary education level. This study will hopefully provide a platform for the development of a biotechnology curriculum responsive to African needs and epistemologies. The value of this study lies in formulating and developing the biotechnology curriculum, and Teaching and Learning (T&L) of it, an 'African product', rather than as an export of decontextualised western science.

Keywords: *Biotechnology; cross-border tertiary education; African epistemology*

INTRODUCTION

Globally, universities, research institutions and industry work towards the development and application of biotechnology. Areas of interest include crop agriculture for food security, animal and human health and environmental sustainability. All these are of utmost importance, not only globally, but also in southern Africa. Consequently it is vital that the skills required for establishing biotechnology knowledge should be promoted through capacity training at tertiary institutions. Capacity development refers to the process whereby organizations and society adapt and maintain capacity over time. Capacity development therefore depends on progressive involvement in the field concerned and the achievement of high skills by those working in it. Tertiary education contributes to capacity development by training a country's human resources in fields relevant to its development (OECD, 2007).

Biotechnology has become one of the University of the Witwatersrand's (Wits) important research areas. This follows the global trend in this discipline, and in recognition of this trend, the University of Namibia (UNAM) has introduced new biotechnology courses into their curriculum. A project which involves regional co-operation through cross-border teaching and collaboration was set up between Wits and UNAM to help build up and strengthen existing biotechnology capacity at Wits and develop biotechnology capacity at UNAM (Mthembu, 2006). The project had its beginnings within a larger project called the South African-Norway Tertiary Education Development Programme (SANTED).

SANTED was a Norwegian-funded, government-to-government development project which ended in August 2009. Its major objectives were to enhance co-operation and build partnerships between Universities in southern Africa and to develop capacity in both the theory and applications of biotechnology through the introduction of relevant curricula and the strengthening of existing curricula. The outcomes of this project include (1) the introduction of biotechnology courses at UNAM, which were approved by the UNAM Senate at the end of 2007. These modules are in the 3rd and 4th years of the new curriculum and taught for the first time in 2009 and 2010; (2) the regional cooperation through cross-border teaching and collaboration between Wits and UNAM in developing the skills for the theory and application of biotechnology at the tertiary education level; and (3) the recognition of potential worldview differences i.e. western versus African. According to Cobern (1996) 'worldview' has to do with an individual's presuppositions about what the world is like and important knowledge about the world. A science worldview is concerned with acquiring knowledge through predictions. Such knowledge is regarded as universal, whereas from the perspective of an African worldview, knowledge is a gift from the ancestors. It is a social and tribal entity which is not regarded as universal (Hamminga, 2009). This paper will describe the process of this project so far, and is a continuation of the paper presented at the 2008 IOSTE symposium, which described the SANTED project and the workshops involved to enhance co-operation and build partnerships in tertiary institutions in 3 countries in the Southern African Development Community (SADC).

LITERATURE REVIEW

This literature review is made up of three sections which provide the background for this research. These are biotechnology, epistemology and tertiary education. The first section, comprising **the nature of agricultural and plant biotechnology (APB) in southern Africa,** addresses the status of biotechnology in South Africa and Namibia; biosafety concerns; and the legislations, policies and regulatory frameworks in place. The next section, **the nature of epistemology**, looks at African epistemology and traditional ecological knowledge. The final section, **the nature of science in tertiary education,** gives a brief overview of cross-border education and how an understanding of African epistemology can lead to a culturally sensitive curriculum.

The nature of agricultural and plant biotechnology (APB) in southern Africa

Biotechnology in South Africa

South Africa has a history of engagement with traditional biotechnology. This has led to one of the largest beer brewing companies in the world (South African Breweries) and to the development of excellent wines (Ngubane, 2001). In addition to alcoholic beverages, it has also led to the utilization of its natural plant and animal diversity, for example the protea and kwagga breeding programmes and the National Research Foundation Indigenous Knowledge Research programme encouraging academics to look at medicinal plants. Traditional biotechnology has been practiced by indigenous peoples in southern Africa for centuries, as in the brewing of local beers from sorghum or marulas, and to the mating of cattle to produce particular colour patterns. Modern biotechnology, however, requires the use of carefully controlled laboratory procedures which are only available as a result of modern science and scientific procedures. Modern biotechnology involves manipulating DNA, and refers to the use of genetically modified (GM) organisms in agriculture and industry (Campbell and Reece, 2005). South Africa is now the 8th highest producer in the world of genetically modified foods, planting more than 1.8 million hectares of GM crops in 2008 (GMO Indaba, 2009). S.A. is at the forefront of the research on crops of both economic and cultural importance. These crops include various cereals: maize, wheat, sorghum, millet and soybean; various vegetables: cassava, yam and sweet potato; various other economically important fruits and flowers (Brink et al., 1998). GM crops are now grown by both commercial and small-scale farmers. APB techniques include tissue culture programmes established for application in root and tuber crops and ornamental and horticultural crops; genetic engineering projects (both public and private) for the commercial growth of insect-resistant maize and cotton and herbicide-tolerant soybeans and cotton; marker-assisted selection is applied in maize and small-grain breeding; molecular diagnostics and markers are used for plant disease diagnosis; biological nitrogen fixation is applied in soil fertility improvement by using legumes and inoculants.

Legislations, policies and regulatory frameworks in South Africa

South Africa has developed APB to a position where infrastructure and regulatory frameworks are adequate to facilitate Plant Genetic Engineering (PGE) as well as the commercialization stage of GM crops. South Africa has a legally-binding Genetically Modified Microorganisms Act (Act no.15 of 1997) and the country adopted the National Biotechnology Strategy in 2001, which created a policy framework to establish incentives for the biotechnology sector, and led to the establishment of Biotechnology Regional Innovation Centers (BRICs) throughout the country. These centers function to conduct and fund biotechnology research and to introduce initiatives to encourage international partnerships. The formation of the regulatory framework permitted the commercialization of existing knowledge from biotechnology research (Brink et al., 1998).The South African Department of Science and Technology’s (DST) ten year innovation plan (2008-2018) aims to drive transformation towards a knowledge-based economy, in which the construction and propagation of knowledge leads to economic benefits. One of the grand challenge areas of the DST, the “farmer to Pharma” value chain, aims for South Africa to become a world leader in biotechnology and pharmaceuticals, based on the nation’s indigenous resources and expanding knowledge base.

Biotechnology in Namibia

In Namibia the types of APB techniques that are used include Tissue Culture for producing cassava and Irish potato and for micropropagation and disease elimination. Serological techniques and biological Nitrogen fixation is applied for legumes.

Namibia participated in a research project coordinated by John Innes Centre, Cambridge University, United Kingdom, involving the enhancement of pearl millet for downy mildew resistance (http://www.wisard.org?wisard/sharedsp/StrCountrySelect.asp?CountryA2+NA). This project was completed in 2003 and involved the fine-mapping and isolation of genes underlying downy mildew resistance in pearl millet through breeding schemes of selected lines together with the characterization of quantitative trait loci for resistance (http://www.cababstarctplus.org/abstracts/Abstracts.aspx?AcNo=20043053248). Namibian research teams together with teams from South Africa and Europe have worked on projects investigating the development of insect resistance in important African crops such as Bambara groundnuts and Marama beans and fungal resistance in millet (ABSF AFRICA, 2009).

Legislations, policies and regulatory frameworks in Namibia

In Namibia the Biosafety Bill was passed in 1999 and since the signing of the Cartenega Protocol on Biosafety in 2000 and the endorsement thereof in 2005, biotechnology has gained ground. The Namibian Biotechnology Alliance (NABA, 2004) is a forum that is involved in developing and promoting biotechnology use and research within Namibia. It developed the National Biosafety Framework in 1998 and has done research into "Awareness in Biotechnology and Biosafety" and "Identifying the agricultural needs that could be solved through Biotechnology" (NABA, 2004). The Ministry of Agriculture, Water and Rural Development administers the Biotechnology research policy for Namibian APB development. Namibia do not import any genetically modified products and have a strict border control which requires a certificate, possible tests and rejection if the product is genetically modified

(http://www.fao.org/biotech/inventory_admin/dep/country_rep.asp?country+NAM.).

The nature of epistemology

African epistemology

According to Bakari (1997) African epistemology is characterised by strong interpersonal relationships, peace with nature, communalism and spirituality. This epistemology places emphasis on ethics and morality, symbolic imagery, self-awareness and tradition (Bakari, 2007). Indigenous African epistemology has both geographical and cultural factors that contribute to an African identity (Higgs, 2007). Relevance and usefulness remain central to the African philosophy. Community and belonging to a community of people is also very important to traditional African life (Higgs, 2007).

Higgs (2007) refers to African community-based research and he argues that the indigenous African epistemologies for research in higher education are centred in communalism, where a community is described as a number of people who have something in common that distinguishes them from others. This can be geographic, language, ethnic or religious identification. African community-based research is process oriented and it aims to strengthen the knowledge that exists in a community.

In countries where people of European descent coexist with indigenous people, especially where the indigenous people are in the minority (United States, Canada, Australia, and New Zealand), their systems of indigenous knowledge have been almost or completely destroyed due to them having undergone a "culticide" through the colonizer's educational systems (Van Eijck and Claxton, 2009). In Africa, knowledge is culture-laden and this knowledge is generally passed on verbally through generations where it is more about preserving existing knowledge and wisdom from the past, rather than generating new knowledge. It is not given much attention in formal science classrooms. Van Eijck and Claxton (2009) encourage science educators to overcome trends in science curricula that discourage indigenous minorities in sustaining their worldviews and they encourage students to consider how technology-based topics reflect moral principles and virtues that are part of their lives.

Traditional Ecological Knowledge

Instead of seeing science as a universal way of knowing, there are many who adopt a cultural perspective that treats science as a human practice relating to Traditional Ecological Knowledge (TEK) (Snively and Corsiglia, 2000). TEK refers to how humans come to understand the natural world around them. It is a term coined to describe knowledge attained through time and patient observation of the natural world – it can have 'science' in it, but connections made may be out of the sphere of western science as it is defined, i.e. through evidence and experimentation (Van Eijck and Claxton, 2009).

If we unpack the term Traditional Ecological Knowledge (TEK), "Traditional" refers to a cultural continuity transmitted through social attitudes and beliefs derived from historical experience. However, as societies or communities change over time and adapt to their environment by adopting new practices and technologies the typical definition of "traditional" becomes difficult to formulate, and the term "ecological knowledge" is also difficult to formulate especially since ecology is defined as a branch of biology in the area of western science. Some authors prefer the term Indigenous knowledge (IK) to TEK as it puts the emphasis on indigenous people. TEK and/or IK refers to knowledge acquired over thousands of years of human contact with the environment, and sometimes this is information that is passed on orally and it is shared only if it will not be used for gain (Snively and Corsiglia, 2000). Science lecturers at the tertiary level in Africa are often educated in foreign countries or they are educated following a western curriculum in their home countries and therefore know more of Western modern science (WMS) than their own indigenous sciences. The Global Education Digest 2009 reports that one out of every five foreign students from Africa is studying at a South African university (10 168 from Namibia). According to this study one of the reasons they leave their home countries is because of under-resourced universities (Govender, 2009).

The nature of tertiary science education

Cross-border tertiary education

Internationalization of higher education is described as "the process of integrating an international intercultural and global dimension into the purpose, functions (teaching, research, service) and the delivery of higher education". Internationalization activities apply to cross-border projects and campus-based activities. Cross-border tertiary education falls within educational internationalization and refers to the movement of people, programmes, providers, curricula, projects, research and services across national or regional jurisdictional borders (OECD, 2007). UNAM and Wits are the first southern African institutions to consider cross-border tertiary education as a helpful capacity development tool in plant biotechnology. However, a consideration of African epistemological access should inform this cross-border tertiary education capacity development.

According to Laugksch (2000), in education the term 'scientific literacy' equates to the development in a person of the ability to understand the nature of scientific knowledge, to use science in solving problems, and to appreciate the connections between science and technology, and between these two and society. Science and technology tertiary education in southern Africa is offered in multicultural classrooms where different views of science may be firmly rooted in certain cultural assumptions. This influences how students formulate and solve problems (Stanley & Brickhouse, 2000). Students of different cultural backgrounds can interpret science concepts differently, indicating that teachers should prepare a science curriculum suitable for use in a multicultural classroom by using the prior knowledge that the students bring to class. Snively and Corsiglia (2000) argue that the curriculum should recognize a community's indigenous knowledge or worldview in a way that creates a need to know Western science, i.e. by including IK and WMS content to study certain fields of interest more thoroughly, thus enriching understanding of the environment in a sustainable way.

METHODOLOGY

With the introduction of biotechnology courses at UNAM, the regional cooperation through cross-border teaching and collaboration between Wits and UNAM was set in motion. This involved team teaching where a Wits representative visited UNAM to share scientific knowledge in the area of plant biotechnology principles and techniques involving genetics and microbiology, together with issues around genetically modified organisms (GMOs). This topic covered plant genomes, the organization and expression of genes, plant tissue culture and techniques for plant transformation, vectors for plant transformation, the expression and stable inheritance of transferred genes, together with safety and environmental considerations. This was accomplished in 7 one hour lectures throughout a week in the second semester of 2009. Communication across borders in southern Africa is very slow and setting up the week of lectures took 2 months of email contact.

As this study is intended to investigate issues of epistemological access which will inform cross-border teaching and learning in Biotechnology through the process of co-operative capacity development at the tertiary education level in the two diverse, multicultural universities. A qualitative design is used because qualitative research is flexible and concerned with process, and understanding the process (Merriam et al., 2003, Merriam, 1998). The research process continually evolves and unfolds, because the study seeks to understand a dynamic and continuously evolving process (Merriam et al, 2003). In researching epistemological access, the research function is to describe the different worldviews of the teachers and learners involved and whether they lead to epistemological barriers. The research will involve a case study approach in which the methodology of Design Research will be employed (Leedy and Ormrod, 2005; Plomp, 2008) using a worldview theory as the theoretical framework (Cobern, 1996). The worldview theory provides the environment for examining the reasoning and thinking of teachers and learners.

Design Research is an alternative research approach. Plomp (2008) uses the term 'design research' as a common label for a group of related research approaches which vary a little in goals and characteristics e.g. design studies, design-based research, developmental research, formative research and engineering research. The search for 'understanding' or 'knowing' is the key focus of any scientific research, and it aims to add to the body of knowledge or theory in the field of the research. The broad focus of educational design research is to provide 'insights and contributions for improving practice', and to enlighten decision making and policy development in the field of education (Plomp, 2008).

Usually in a case study a global issue is explored through a specific case (Merriam, 1998), i.e. biotechnology is becoming a major research thrust globally and in this specific case, the development of biotechnology capacity in southern Africa at the tertiary education level. In a case study, a program or individual is studied for a defined period of time (Leedy and Ormrod, 2005). In order to gather worldview and epistemological information, a semi-structured interview format will be used, together with questionnaires for assessing worldviews of biotechnology teaching and learning images.

The data will be analyzed inductively using the constant comparative method (Merriam et al. 2003; Glaser and Strauss, 1967; Strauss and Corbin 1998). This method of data analysis involves comparing concepts or categories coming from one data set with concepts from another data set , and then looking for relationships and themes between these concepts until "analytical 'saturation'" is reached (Badenhorst, 2008). Triangulated data collection which involves researching the same research question from more than one source of data will be gathered from the two institutions in the form of semi-structured interviews, observations and questionnaires.

Participants

For this paper, which is the implementation of a long term project, the participants include two of the lecturers involved in teaching the biotechnology courses at each institute and the learners are a convenience sample from the 3rd year students in the Department of Biological Sciences at UNAM (currently 22 registered). Ethical clearance has been obtained for this research and the information obtained from students and lecturers involved in biotechnology will be used to inform a culturally sensitive biotechnology curriculum in future.

Reliability and validity

Tacit and formative theories have an effect when collecting qualitative data (LeCompte, 2000). Tacit theories could bias information, as they guide daily behavior, explain the past and predict the future. Formative theories are more formal and used in research, although they also guide behavior, create explanations and predict the future (LeCompte, 2000). Transforming data into research results is called analysis. Good analysis is based on clearly articulated theories, and responsiveness to research questions. Creating meaningful results involves validity, or whether or not research findings seem accurate or reasonable to the people involved in the study. Validity also refers to whether or not results obtained in one study can be applied to other studies with similar situations (LeCompte, 2000).

According to Badenhorst (2008) the traditional criteria for judging quantitative research are internal validity, external validity, reliability and objectivity and the parallel alternative criteria for judging qualitative research are credibility (how truthful the findings are), transferability (how relevant the findings are to other settings), dependability (how consistent and reproducible results are) and confirmability (how reflective of all involved parties are the findings).

The latter four criteria are applied in research designs through triangulation, which involves researching the same research question from more than one source of data. Campbell and Fiske (1959) introduced the concept "triangulation" as a synonym for convergent validation, meaning that information from different sources can be used to substantiate and illuminate the research problem and therefore limit any biases, personal or methodological. Denzin

(1978) identified 4 types of triangulation i.e. data triangulation, method triangulation; investigator triangulation, and theoretical triangulation. Data and method triangulation will be applied in this research.

RESULTS

The 2009 cohort of 20 third year undergraduate students were the first to be introduced to the new biotechnology courses that were discussed and planned at the SANTED curriculum development workshops held at WITS in 2006 and 2007. There are two third year biotechnology courses in this new curriculum, i.e. Recombinant DNA Technology, which was taught in the first semester and Biotechnology, which was taught in the second semester.

A questionnaire on this "SANTED week of lectures" as it was called, was completed by the students and the UNAM lecturer involved, for feedback to SANTED. They were conscientious in answering the questionnaire answering all the questions and carefully unpacking the information. Although the students are taught in English, they have a variety of different home languages i.e. Afrikaans, Damara, Damara-nama, Oshiwambo, Oshindonga, Otjiherero, Rukavanga, Rukwangali, and Setskiana, which highlights their cultural diversity. Defining the term 'biotechnology' is not an easy task, since it can mean different things to different people, as it is connected with various needs and interests. Through their answers the students showed that they had very distinctive ideas of the term biotechnology and what it meant to them. These students had attended a semester of Recombinant DNA Technology and two weeks of this module called Biotechnology. Ten out of fifteen respondents felt that it could improve society, provide treatment for disease and provide food security. Of the other five students, two felt that it could improve agricultural production, generate income and be of economic use, and the other three gave definitions of the term. This was the first time biotechnology topics were being taught at UNAM, so students were asked when their first biotechnology learning experience had been. Most students referred to the topic experience they were involved with at the time. One student mentioned baking bread and watching the dough rise and that they also felt excited about bananas without seed, and red oranges. Students were very open and frank and said their motivation to learn biotechnology came with the fact that it was now part of the curriculum, so they had to do it, but they all liked the idea. One student even took it as far as wanting to be a good scientist and "change Africa from poverty". Students felt they were learning biotechnology when they were learning the genetics and microbiology background, and when they were involved in practical laboratory work. These practical laboratories involved extracting DNA from cells. The students also enjoyed seeing the practical results of other students' work, for example the third year practical results from Wits laboratories. This week of plant biotechnology was interesting for them and they felt they had gained additional and empowering information. Their answers to their motivation to do biotechnology highlights that they did not directly choose it as a subject but just ended up having to do it as part of the curriculum. However, they felt it would have opportunities for them. The following quote by one of the students sums it up: "Genetic manipulation and transformation section really change my life to do biotechnologies (sic)".

The students enjoyed all the modules and sections on biotechnology they had done. They had very positive comments about the "SANTED" week. They found it "very useful" and learnt many new concepts about plant biotechnology they had never realized before. The students felt lecturers from other universities contributed to their learning "as they teach differently” and “bring different knowledge”. Some seemed to feel that UNAM was less advanced and lecturers from other universities would be up to date with the current scientific world. Another opinion was that we “could all share our knowledge and learn new things by having lecturers from other universities”. Yet another felt that it is a way of “learning about each others cultures” and sharing “traditional norms and values”. One student felt that “knowledge is power and biotechnology is one of them”. Another wrote that armed with this knowledge, he or she felt they could “now have a conversation with other lecturers”, which shows how empowered the students felt by this new curriculum and the SANTED experience of a ‘lecturer from across the borders’.

The common theme that was evident from the lecturer’s and the students’ responses to the questionnaire, especially with regard to SANTED, is that they were very positive. It empowered them to know they were learning what other students learn at other universities; they enjoyed the exposure to a different teaching style; and interacting with the information they were being introduced to. They liked the idea of lecturers from other universities teaching them as it made them feel confident about what they were taught, giving them a sense of security about the knowledge they were acquiring. This shows the effect globalization has already had on the way these students view and receive knowledge.

CONCLUSION

The students felt enriched by this experience and quotes from the questionnaires bears testimony to this: “I really enjoyed this week. It made me see the real application for biotechnology” and “Thank you for an educative and informative week!” These are just two of the many comments that highlighted the worth of the week for the students. The broad focus of educational research is to provide ‘insights and contributions for improving practice’, and to enlighten decision making and policy development in the field of education (Plomp, 2008). The lecturers involved at Wits and UNAM and the Pro-Vice Chancellor, Administration and Finance, of UNAM indicated that they would like to see biotechnology capacity development and the sustainability thereof.

African community-based research intends to integrate indigenous African knowledge systems, founded on indigenous cultural and social values, with modern knowledge systems, while simultaneously exposing indigenous communities to scientific knowledge production and dissemination (Higgs, 2007). From this initial interaction it is evident that in southern Africa globalization is implicated and accepted in the development and application of biotechnology, especially from the economic point of view of food security, animal and human health and environmental sustainability. In accommodating student and lecturer input we hope to be able to include African knowledge systems with modern knowledge systems in creating a new curriculum which will be in keeping with southern African sociocultural and human values.

ACKNOWLEDGEMENTS

Wits International Office, for organizing flights and transport to and from the airport in South Africa. The Office of the Pro-Vice Chancellor, Administration and Finance, UNAM, for organizing the accommodation and transport from and to the airport in Namibia, and SANTED for the financial support to achieve this.

BRIDGING THE GAP: THE ROLE OF EXPERIENCES IN INFORMAL EDUCATIONAL SETTINGS AS PART OF INITIAL CHEMISTRY TEACHER TRAINING

Bruno Andrade Pinto Monteiro

Universidade Federal de Lavras

bpmonteiro@ufla.br

Isabel Martins

Universidade Federal do Rio de Janeiro

isabelmartins@ufrj.br

ABSTRACT

The argument that science education can be fostered by actions in both formal and informal educational settings has been increasingly put forward by the research community in the context of discussions about the need to promote scientific literacy. Such perspective challenges teachers who were trained in traditional programmes. Based upon Bakhtin's account of the role of language in understanding the social practices and on Bourdieu's concept of cultural capital this study analyses the discourses of a group of chemistry teachers about informal education. Preliminary results obtained through textual analysis reinforce the relevance of the theoretical framework and reveal multiple voices in beginning teacher's discourses about the role of teacher, school settings and informal education. Accordingly, we believe that the science teachers, or educators traditionally trained to act in formal education are facing new challenges, for example, the task of developing practices of science education in contemporary educational places made possible by approximation of the formal and informal spaces of science education.

Keywords: *teacher education, museums, discourse analysis.*

1. INTRODUCTION

The argument that science education can be fostered by actions in both formal and informal educational settings has been increasingly put forward by the research community in the context of discussions about the need to promote scientific literacy (HONEYMAN, 1998; GOUVÊA et al, 2001; FALK, 2002; QUEIROZ et al, 2002; GRUZMAN & SIQUEIRA, 2007). From this perspective, the Declaration of Toronto (TORONTO, 2008), a document elaborated in the last World Congress of Science Centers in June 2008 presents a series of goals, guidelines and beginnings that should orientate the actions of the Museums and Science Centres. In this text it is possible to notice that there is a high recognition of the educational function of the MSC by society which represents a change in the perspective that restricts function of Museums and Science Centres to scientific popularization. According to the document, besides promoting scientific literacy, Museums and Science Centres constitute inclusion spaces and of social change that possess influence in education and in the development of society. In this paper we argue that science education can be favoured by the articulation of actions in formal and informal environments and describe a teaching sequence whereby teachers in initial education programmes in Brazil have experienced and discussed the possibilities of planning, implementing and evaluating activities in the school and in museum. The idea was to prepare future teachers to the challenges involved in integrating students' experiences in and outside school.

Studies by Queiroz, Gouvêa and Franco (2003) diagnosed that practicing teachers who accomplished school activities in the Museu de Astronomia e Ciências Afins (MAST/ Brazil) recognized the importance of the articulation among informal spaces and school.

Nonetheless, they reproduced a traditional school pedagogy during museum visits with their students. (QUEIROZ, GOUVÊA & FRANCO, 2003). The authors' literature review stresses that initial teacher training programmes in Brazil do not prepare teachers to benefit from what museums and science centres have to offer. This is problematic because there are statistical data to confirm that, unlike students from carreers of greater social prestige such as Medicine and Odontology, future teachers tend to come from low income backgrounds which have limited access to cultural heritage (e.g. theatres, cultural centers, museums, art galleries, music rooms, libraries etc.) (CAZELLI, 2005). In this way, we think that there must be concrete opportunities in initial teacher training programmes for these future teachers to acquire social and cultural capitals necessary to fully explore the potential of museum and science centres in their teaching practice.

2. THEORETICAL FRAMEWORK, METHODOLOLY AND RESEARCH QUESTIONS

In this work, we presented the first stage of our research conducted with a group of 22 beginning Chemistry teachers from the Federal University of Lavras. The investigation involved the identification of discursive changes in the students' discourses during a four month (68 hours) course on the role of informal educational spaces and their relationships with school. The course involved readings about (i) the relationships between education and culture; (ii) the notions of cultural heritage and scientific culture; (iii) the role of museums and science centres as promoters of scientific literacy; (iv) descriptions of activities integrating experiences in formal and informal educational environments. The course also included four guided visits to science museums and the elaboration of a teaching sequence to be implemented by the beginning teachers. The sources of data of the research consist of the texts elaborated by the beginning teachers (paper/book reviews, field notes, essays, answers to questionnaires etc.) and of videorecordings of classroom activities and of museum visits. Follow-up interviews were also conducted and transcribed *verbatim*. Our analyses sought to identify textual marks that reveal how these 22 beginning teachers interpreted and understood the possibilities of integrating activities in formal and informal educational environments.

The investigation was based upon theoretical concepts of the philosophy of the language, especially on the contributions of Bakhtin, and in concepts of Bourdieu's sociology. We understood that the situations produced in the spaces of initial teacher training programmes can be understood as a group of institutionalized and located social activities in cultural atmospheres. They provide a socio-conceptual horizon from which positions are taken and points of view are constructed. Utterances, for Bakhtin (1988), are influenced by external factors and the situation and the most immediate participants determine their form and the style. We will therefore seek to establish relationships between beginning teachers' utterances and features such as their socioeconomic background, their views about science and society and their readings of materials that circulated during the course. Besides, we understand that the texts and speeches produced by the beginning teachers are constituted by a plurality of other speeches. The vision of Bakhtin considers that the texts are constituted by different "voices", that is to say, in the act of production of an utterance the speaker incorporates countless social positions they represent the plurality of representations, points of views, values, conceptions etc. With reference in those theoretical presuppositions, we are mainly interested in identifying and in characterising discursive marks that demonstrate which social voices constitute our beginning teachers' discourses, how they are present in their speeches and if they contain references to voices of official speeches that mark ideological positions in relation to the role of the teacher, of the school, of museums and science centres and, also speeches that demonstrate epistemological visions of the Science. Bourdieu (1998) reiterates the need to consider the social conditions and power relationships in the analyses of the linguistic phenomena. The contact point between Bakhtin and Bourdieu enables the interpretation of the beginning teachers' discourses in the social context of their production, that is, in the context of an experience set up as part of formal education. This perspective points out that, during the interactions which happened during the course and in the visits to the museums, meanings were negotiated between the participants. For Bourdieu, in the verbal interactions between individuals or groups there are confrontations between ideologies and each one tries to impose their *"categories of perception of the social"* world through argumentative efforts (BOURDIEU, 2007). This is why our empirical data consists of verbal expressions generated in different social contexts.

However, a challenge of this study refers to the fact that, according to Cazelli (2005), cultural spaces like museums and science tend to be seen by the low income population as spaces which belong to the elites and that are legitimated by social processes, for example within the family or during school socialization, that distinguish groups and individuals with respect to the ownership of symbolic and material cultural capital and by the constitution of different *habitus*. (CAZELLI, 2005). This author reiterates that *"to visit theaters, cultural centres, museums, art galleries, music rooms, libraries are not part of the cultural horizon of disadvantaged groups in society"*. (CAZELLI, 2005). Social representations concerning museums and science centres can, in this way, reproduce power relations of the economically favoured classes that control the access to the cultural heritages. We understood, through both direct observations and analysis of preliminary data, that this could be the case for the beginning teachers who were subjects of this research. For this reason we tried to create concrete opportunities and support material for them to take part in the activities that required critical observation of environments they might not be familiar with or, worse, felt intimidated by.

Starting from this theoretical framework and problematisation, this research to understand, in the context of a particular educational experience set up as part of an initial teacher training programme, aspects concerning:

(i) the relationships between future teachers' sociocultural conditions and their possibilities to consider articulations between educational practices involving schools and museum and science centres;
(ii) the social voices that are present and which constitute future teachers' discourses about possible relationships and possibilities of teaching science through the articulation of activities in school and in informal settings
(iii) the understanding that beginning teachers possess about: the teacher's role, the relationships between schools and museums and science centres, epistemological conceptions of science; curriculum recommendations etc.

In order to explore these points we will discuss relationships between two sets of data: beginning teachers' answers to a socio-enconomical questionnaire and textual analyses of an essay written by them during the course. The analysis will explore relationships between their socio-economic profile, their expectations and their appropriations of ideas that integrated texts presented and read during the course.

3. RESULTS AND DISCUSSION

3.1 EVALUATION OF SOCIOECONOMIC PROFILE GROUP

It was possible to map out the socio-economic profile of the subjects of the research according to their answers to a socioeconomic questionnaire filled in at the start of the course. The beginning teachers who took part in the study reside in the southeast of Brazil, in the central state of Minas Gerais. About 45% of the students came from cities with population range between 10.000 to 60.000 inhabitants around the city of Lavras, where the university is. Seven were male and 15 female, and their age varied between 21 and 25 years old. The total family income of approximately 52% of the students is below U$ 800,00 and the main occupation exercised by the member of the family that more contributes to that income is related to the administration of own businesses. The respondents also informed that they were not frequent goers to museums, galleries of art, concerts, dance/ballet presentations etc. as most of them happened in the capital of the state which is 300 km away from the cities where they live. In other words, most of the beginning teachers informed to have limited access to both material and symbolic cultural equipments (CAZELLI, 2005).

3.2 ANALYSIS OF TEXTS PRODUCED BY THE STUDENTS

A first analysis of the texts produced by the beginning demonstrated the presence of several social voices, related to different educational discourses. The texts are therefore heterogeneous and polyphonic, in the sense that they indicate discursive markers of points of view associated to different sociocultural horizons, related to discussions about teachers training and to new demands faced by science education. Our analyses started with the examination of an essay written by students at the beginning of the course about what they felt were the possibilities offered by informal educational settings in the teaching of natural sciences..

As we can exemplified below in box 01 that shows a fragment of Carla's text, there is a clear recognition that school is not the only possible or productive setting as far as science education is concerned. Carla points out three examples, museums, computer science laboratories and open fields, and stresses the need for specialized knowledge which would enable teachers to benefit from their full educational potentials. This vision agrees with views expressed by educators from museums and science centres that were present in texts discussed during the course such as work of Cazelli et al ideas that students should not be limited to the school environment 2002) and texts by Gaspar (2002) which discuss new possibilities for the development of educational practices in multiple settings.

> "Several settings can be used for the education in sciences: museums, computer science laboratories and even an open field. It is just a matter of knowing how to explore the potentials of each setting".

Box 01. Fragment of Carla's essay.

Carla goes on to point out that both schooling and experiences provided by the teachers may have a role in ensuring accessibility of students to museums. This idea alludes to the discussion undertaken by Castro et al (2001), on the difficulties faced by people living in conditions of social exclusion in their daily lives. This author states that these young people are deprived of taking part in social networks that revolve around the cultural assets of society.

> "[...] A visit to a museum, for example, can provide access to an area never visited before, that may never have been visited because of lack of information and/or opportunity".

Box 02. Fragment of Carla's essay.

References to 'traditional methodologies' were also frequently deemed negatively and associated to many initial teacher training programmes:

> "The traditional education based on the booklet `chalk and talk' is weak though still present in many courses.

Box 03. Fragment of José Carlos' essay.

In box 04 below, Carla mentions relevant aspects that reveal her views about 'traditional' science lessons. As we can see, there is an implicit view of science education as associated to scarcity of teaching resources, knowledge transmission and negative attitudes towards science. Cazelli et al discuss such ideas in relation to aspects of standard liberal-traditional pedagogy, where "education is focused on the teacher who, before an audience considered as *tabula rasa*, transmits orally in an organized manner and with the help of audiovisual resources, a set of consolidated universally accepted contents" (Cazelli et al, 2002). Carla points to the need to explore other resources, apart from blackboard, chalk and books, but does not go as far as criticizing the epistemological bases of standard universalistic content-based approaches to the teaching of science. Another interesting aspect is the conflicting views that Carla brings about in her text concerning a negative depiction of "terror" that obscures the beauty of science education. It is interesting that such an association suggests that the climate of terror, imprinted in these disciplines may be attributed to factors linked to teacher's actions or to the school environment itself, since the science education is seen as inherently beautiful.

> "So the teaching of science should not be like it was years ago: blackboard, chalk, teacher and book. It is possible and necessary to explore other areas to make the subject matter more interesting and so that the "terror" that surrounds the disciplines of chemistry, physics and mathematics is left aside and students can see the beauty of science education.

Box 04. Fragment of Carla's essay.

In the fragment presented below, taken out from Solange's essay, there is also a reference to the role of the teacher who adopts 'traditional' approaches and their consequences. The articulation of experiences in schools and in museums and science centres is, in this context, clearly considered as an innovation and Solange's texts refers to a widely available image of both conservative and authoritarian behavior followed by many teachers who are reluctant to incorporate new methods and approaches in their practice. At the same time there is an acknowledgment of the role of research in changing this image.

> "[...] Large scale projects and research are taking away that image that the science teacher is as an authoritarian person who goes to the classroom only to 'spit' contents over students."

Box 06. Fragment of Solange's essay.

This image, which is decontextualised from historical considerations that might account for the roots of teachers' resistance to change, does not take into account limiting factors that can explain why the implementation of new approaches may not be so easy in some cases. However, some of the essays written by the beginning teachers also expressed views about aspects of teaching as a profession, namely, remuneration, work conditions, social status etc. that could have an impact on the kinds of activities and possibilities to implement changes that explore articulations of experiences in formal and informal settings. Unfavorable social perceptions as well as the low status attributed to teaching in society are reasons to justify teachers' difficulties to promote changes in such direction. In the fragments of texts presented below, taken from the texts produced by other students, we find projections of social horizons and values about the current role of teachers and of teaching:.

> "[...] Teachers, especially those in public schools, do not feel encouraged to promote changes in their classrooms due to the devaluation of teaching both financially and in terms of the professional ideals. Apart from this he often finds himself as hostage of the student.

Box 05. Fragment of Elaine's essay.

In this fragment from Elaine's essay, in box 05, she recognizes the existence of a process of devaluation of public school teachers that affects their motivation and self-confidence. Also, when referring to the depreciation of ideals, she suggests that teachers are not confident about their capacity of being promoters of social change through education. In addition, Elaine uses the hostage metaphor to characterize the relationship between teacher and students as they face the harsh realities of the school setting. This idea alludes to the work of Zagury (2006) where the author argues that contemporary forms of intra-family relationships and the absence of limits for children have led to the fall of the teacher's authority at the same time, transferred to educators disciplinary functions traditionally performed within the family. According to Zagury (2006), factors such as indiscipline and lack of motivation of the students have become the greatest problems of the schools. From this perspective, the teacher became a sort of hostage *"[...] suffering internal pressures of the system - which drives him to implement techniques and methods that will require dedication almost every individual student - and he can not, why not "have time"; From the very consciousness that reveals their inability to conduct a qualitative, as it is currently recommended; Of the students, who now face the challenge openly and in many cases, students' families, who lost his authority over the children and urged the school to do so in its place; The company, which now and then surprised teachers and administrators with precautionary measures, injunctions and processes [...]".* (ZAGURY, 2006). All these factors were presented as obstacles to planning and implementing alternative teaching strategies that might involve visits outside schools and, together with the lack of support, makes it more difficult for them to afford the necessary structural and intellectual investments to experiment with new approaches and methodologies.

4. CONCLUSIONS

The fragments of texts presented above represent a small sample of a wide range of texts produced by students during the course. Most of them, in the texts produced at the beginning of the course, wrote about the educational potential of museums and science centres but, at the same time, problematised the lack of access that both disadvantaged students and underpaid school teachers might have to such places. This discourse echoes voices such as that of Castro et al (2001) who studied the lives of youngsters who face situations of social exclusion and are out of the networks around which cultural goods gravitate. They also think that in such informal learning environments it is possible to provide more positive experiences with science, where students can see the "beauty" of scientific knowledge as opposed to unpleasant classroom experiences commonly associated to failing Science and Maths at school. The majority of texts written after the course beginning teachers widened the scope of the debate and empahsised role of museum visits as instrumental to enabling classroom discussions of aspects related to (i) the history of science; (ii) contemporary science; (ii) socio-scientific issues. Despite that, exhibits and apparatus seen in museum and science centres were often described as illustrations of the subject matter, a point also criticized by Queiroz et al (2003). Only one teacher elaborated on the risk of assuming a naïve attitude towards museums and science centres as places of entertainment. Some teachers portrayed museums in an excessively idealised way, as being always stimulating and interesting, as opposed to traditional classroom teaching, in a way that might lead to an undesirable devaluation of the role of the school. The next step in our analyses relate to a problematization of how these different social voices present in the beginning teachers' discourses engage in symbolic dispute.

As part of research on training of science teachers, we find that there are still many studies that question the issue of possible relationships between schools and the Guest. In our review of the literature on this subject we find very few works about this issue. Thus, we hope to provide contributions that enable further discussions and actions that bring to the degree possible new approaches to teaching science.

ABSTRACT

At Gimnazija Vič in 2006, based on students interests and in cooperation with different research institutions, a special science project was introduced; the most motivated students in the field of science and technology were invited to enroll on the so called "science class". Through the years, an effective way of inquiry based science learning was introduced in every class at the school level.

Science courses are anchored by students' experimental tasks which are carried out under the mentorship of their teachers and/or researchers. The main goal of the project is to improve students' knowledge through the student centered learning and to increase interest of young people in science and technology. The project is fully incorporated into the regular high school curriculum.

The aim of this study is to provide evidence for the effectiveness of the new teaching approach. Students' results at the national final exam were evaluated. Difficulties the teachers and the researchers faced were revealed.

The results clearly indicate that inquiry based science learning and possibilities to work and learn under the mentorship of researchers significantly influence the better quality of students' knowledge and have an important impact on choosing their studies in the field of science and technology.

Keywords: *secondary school science, student centered learning, research education cooperation, inquiry based science learning*

INTRODUCTION

Since the origins of the declining interest among young people to study science are found largely in the way science is taught in schools, the European Commission has tasked several groups of experts to examine the field of science education (GRID 2006b). From on-going initiatives some important common elements of know-how were drawn which could bring a radical change in young people's interest in science studies. Effective long-term research education cooperations are established when there is a possibility of formal agreements based on financial support (Form-it 2007; Lernort Labor, 2009; Robert Bosch Stiftung, 2009, Sparkling Science, 2009). Several examples of good practice show similar characteristics - the role of experiments and practical experiences in the teaching and learning of science is crucial (Euler, 2003). Inquiry-based science education has proved its efficacy in increasing children's and students' interest and attainments levels while at the same time stimulating teacher motivation (Buczynski, 2010; Science Education Now, 2007).

Using constructivist classroom culture in science education young people are motivated to increase interest in different areas of science and technology (Tobin, 1998, Marentič Požarnik 2004, Plut Pregelj, 2008). The understanding of scientific phenomena is developed through students' activity and by appropriate communication among students, teachers and researchers. In school, science courses should be taught in an interdisciplinary way and adapted to the students' cognitive stage (Urbančič, 2007).

At Gimnazija Vič in 2006, based on students interests and in cooperation with different research institutions, a special science project was introduced. The project was initiated by Gimnazija Vic on the basis of 15 years of cooperation with the School in Experimental Chemistry (SEC) at Jozef Stefan Institute and several other research institutions. The main goal of the project is to improve students' knowledge through the practical experience. By introducing young people to the important field of research in science also a positive impact on choosing their studies at university is expected. Given its focus on understanding, science courses are anchored by inquiery based experimental tasks. Students are defined as bearers of in-class activities, as well as out of classroom activities carried out under the mentorship of their teachers and/or researchers at universities of applied sciences, research institutes, and industrial research laboratories and in institutions for popularization of science.

Science courses are focused on active teaching methods, interdisciplinary approaches and hands-on activities. Students tasks/projects are fully incorporated into the regular high school curriculum and/or the science subjects curricula.

Through the school year, students are involved in science projects (individual or team projects) which are carried out under the mentorship of their teachers and/or researchers at different institutions; besides that science days, lectures/discussions on interesting science topics, excursions, field trips and science weeks/research camps are organized. Students' contributions and presentations are assessed in class according to the criteria defined at the beginning of the project/research work; observations of the processes/students' work and the student's points of view are an important part of the assessment.

A team of science teachers has the main responsibility of planning students' activities. Students are mainly involved in identifying interesting topics to be carried out as their project/research work. A catalogue of possible topics to be researched has already been put together by the mentors.

Researchers are involved according to the students' fields of interests and according to the topics in science curricula. The first contacts among researchers and school were established on personal connections mostly, by years a network is building up.

These activities have a strong impact on the teachers who are constantly improving their teaching strategies and didactic approaches. Although the project was initially ment to be limited to the "science classes" only, the teachers were encouraged by the results, and this effective way of embedding inquiry based science learning into the subject curricula was introduced in every classs - at the school level.

The aim of this study was to explore the effectiveness of the new teaching approach at the end of a four-year ongoing project from two points of view:

- The first goal was to show that the students who were actively involved in learning activities/tasks/projects adopted a positive attitude towards the subject; a comparison on intrinsic motivation for learning science subjects and on active learning approaches in the classroom between 1st and 4th "science" classes and the 1st year and 4th year population was made on the basis of a short questionnaire.
- The second purpose of this study was to bring evidence of the impact on students' science achievements at the national final exam (matura) and in increase in the students choice of science subjects as their optional matura subjects since the project was started.

According to the educational researchers (Pintrich, 1999; Devetak, 2009), we also believe that the science project tasks presented a positive challenge to most of the students; they had an opportunity to research a topic they had chosen based on their curiosity and interests; last but not least the possibilities to work and learn under the mentorship of the researchers brought an added value to the students' knowledge.

METHODS

The overall students' results at the external national final exams (matura) in science subjects over a period 2003-2009 were compared to the Slovenian average results. Over the same period the number of students choosing science subject as their optional matura subjects at school was examined.

The results from a short questionnaire on active learning approaches in the classroom and on intrinsic motivation for learning science subjects designed by the authors in 1st and 4th/last year classes were analyzed (six 1st year classes – 183 students, six 4th year classes - 180 students). Since 2006 on, the most motivated students in the field of science and technology are invited to enroll on the so called "science class" (one out of six classes in the generation; 33 students in the 1st year, 30 students in the last year). The results from the questionnaire in the "science classes" were compared to the results at the school level.

We acknowledge that the example provided above is not representative in scope, but it was elected to provide a constrained example in this paper in order to illustrate the features of our research approach.

RESULTS

As mentioned above, at Gimnazija Vič an efficient model has been developed how to embed inquiry based science learning into the school/subject curricula. From the school year 2006/2007, one out of six classes in generation is formed on students' interest in the field of science subjects (approximately 32 students out of 190).

Questionnaire on intrinsic motivation and on active learning approaches results

To get relevant data on intrinsic motivation, the students were asked how much they had been interested in and how much they had enjoyed learning biology, physics and chemistry on the scale from 1 to 5 (5 - the best). The results are shown in Table 1.

Table 6

GRADE	1	2	3	4	5
1st year students					
Biology	12	32	47	66	26
Physics	14	18	49	55	47
Chemistry	15	28	35	57	48
1st year science class students					
Biology		9	8	10	6
Physics		3	3	15	12
Chemistry		1	4	8	20
4th year students					
Biology	15	41	49	53	22
Physics	9	29	46	61	35
Chemistry	12	25	48	56	39
4th year science class students					
Biology	3	2	9	14	2
Physics	1	2	5	14	8
Chemistry			1	12	17

The figures show that 1st year population is slightly more motivated than 4th population for all three science subjects; a shift at higher grades is noticed. As expected, the 1st and 4th "science" class students are far more motivated in science subjects than the overall 1st and 4th year population.

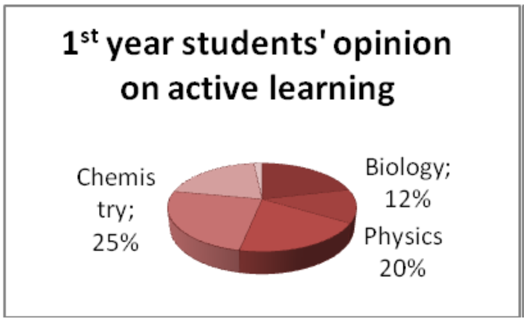
The differences in intrinsic motivation for learning all three science subjects are not significant for the 1st year overall population; however in the "science class" results show different. Although these students were highly interested in the field of science in general, after only half a year in the school, a drop in motivation for biology is noticed. This is also confirmed by the results from 4th year students' population. Again, the differences in students' interest in biology compared to the other two science subjects become greater and more evident in the "science class" (in 2006, with these students the project was started).

By opinion of the teachers, a part of the reasons for that origins from the biology curriculum in Slovenian high schools. Since similar problems (but not to the same extent) were detected on the national level, curricula changes and improvements are planned by school authorities.

On the other hand, although the biology teachers support the project, they are not as enthusiastic and involved due to some objective reasons (among others severe health problems). At Gimnazija Vič, there are two full time teachers (and one part time teacher with less than 0,4 teaching engagement) per science subject, so teacher problems directly reflect on the classroom practice. These results also show the need the teachers have for assistance in implementing new didactical approaches by professional educational organizations.

Based on the results, it can be concluded that a shift from classical teaching approach to the inquiry based one was made more successfully by chemistry and physics teachers; this is clearly pointed out also by the results of the question on students' involvement in the classroom. Students were asked to make an opinion on active learning approaches in biology, chemistry and physics courses by choosing one (or two) out of the three science subjects. This is shown in Table 2 (1st year students' results from the questionnaire on active learning) and Table 3 (4th year students' results from the questionnaire on active learning).

Table 7



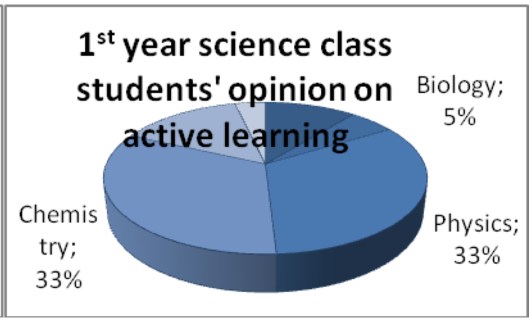


Table 8

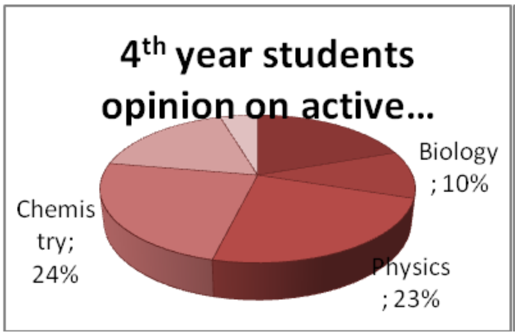
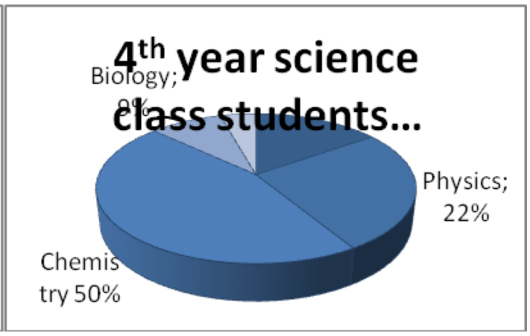




The differences between chemistry and physics courses compared to the biology course are significant in both, 4th and 1st year classes; this is even more evident in the "science classes". As mentioned above, by students' opinion the physics and chemistry teachers are more committed to teaching for students' interest and learning, to active teaching methods, interdisciplinary approaches and hands-on activities than biology teachers.

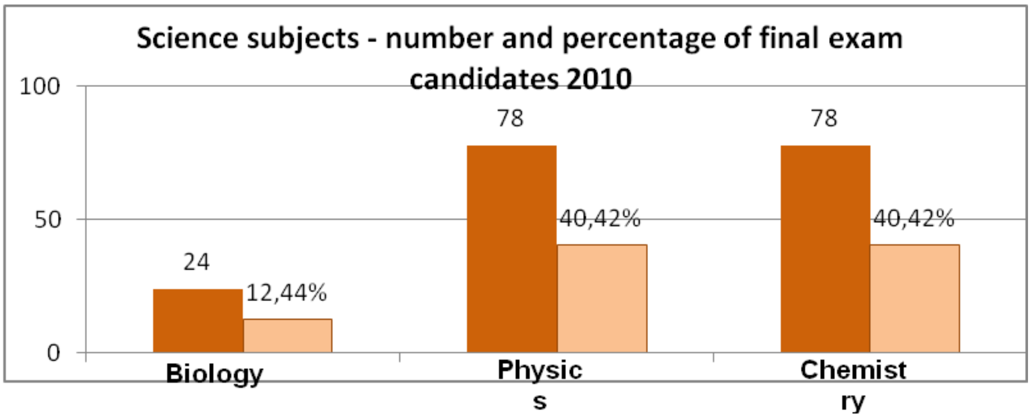
The degree of change seems to be related to the teachers' beliefs about teaching and learning. Teachers need to be willing to move from a lecture-oriented classroom to the student-centered classroom that engages students in inquiry. However, this must be examined in further investigations.

Students' results at the national final exams in science subjects 2003-2009

The results obtained from the questionnaires were also confirmed by the results at the external national final exams (matura) in science subjects. The school national final exam results in science subjects over a period 2003-2009 were compared to the Slovenian average results.

In June 2010, this first generation of the "science class" students will be taking national final exams. We believe that as a consequence of the project, in 2010 a significant increase of the number of students choosing science subjects as their final exam optional subjects has been noticed at school. In Table 4 the number and percentage of the final exam candidates in 2010 are presented.

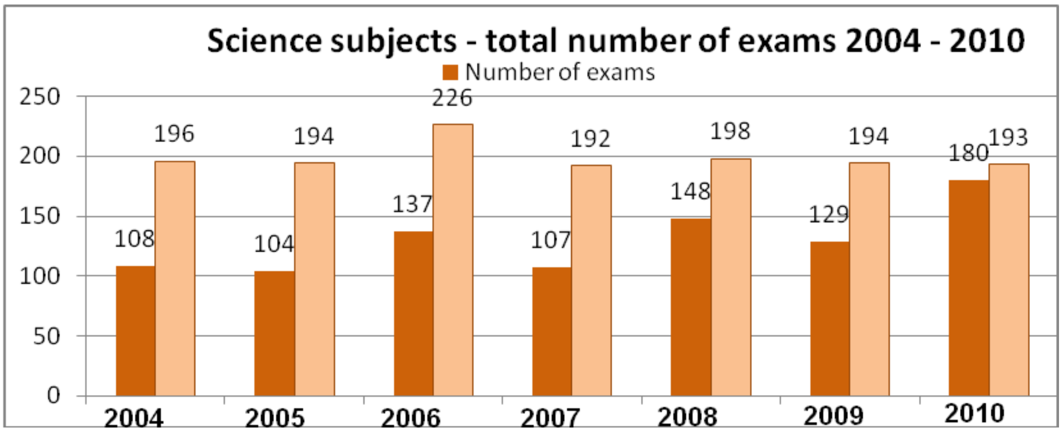
Table 9



Again, it is confirmed how important the role of the teacher is. Although formally team approach is used in all three subjects, physics and chemistry teachers are far more efficient compared to the biology teachers. In physics and chemistry, inquiry based instruction, teaching for students interest and learning, the use of active teaching methods, interdisciplinary approaches and hands-on activities encourages the students' external motivation, which is later on turned into internal motivation based on positive experiences. Thus, the new teaching approaches did not contribute to an increase in the number of biology students, and teachers probably neither apply methods nor perform activities through the course to an extent that would be significantly different from the classical classroom approach.

The number of the science subject exams which students choose as their optional matura subjects over the period 2004-2010 at school was examined; this is shown in Table 5.

Table 10

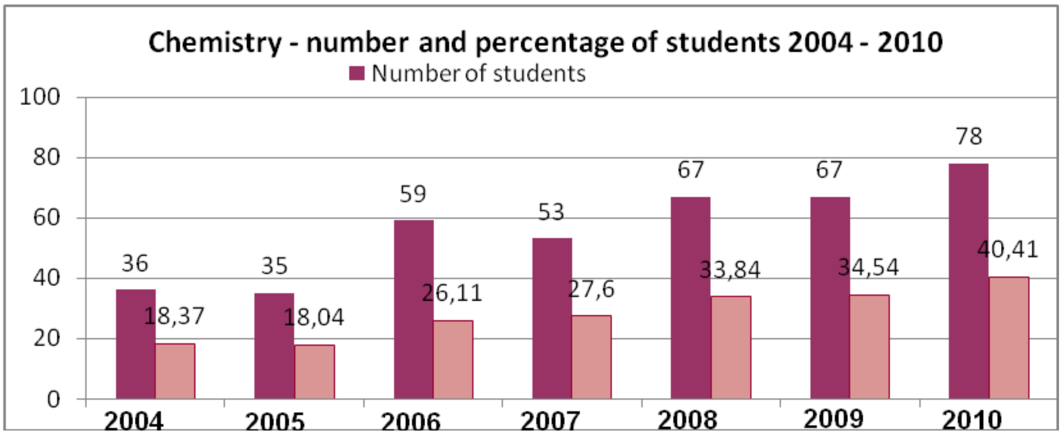


(In 2006, there was an exception of 7 graduate classes - 223 students compared to the usual 6 graduate classes per year, which is approximately 190 students).

Based on the results, it can be concluded that the number of science subject exams compared to the number of students is increasing. Special attention should be paid to the dramatic growth in 2010. Since students' choice of the optional final exam subjects is directly related to their choice of studies, we expect the students' generation 2010 to enroll on the studies in the field of science and technology to a much greater extent than the average Slovenian population.

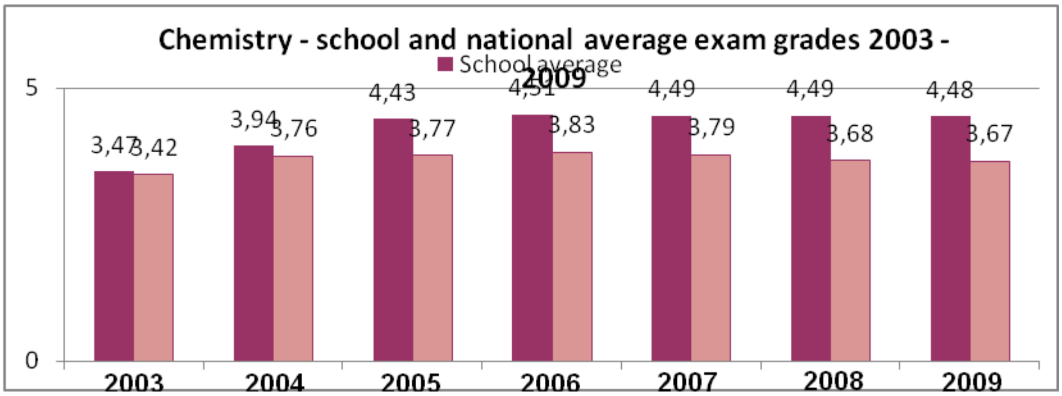
In Table 6, the number and percentage of chemistry final exam candidates over a period 2004-20010 are presented. The whole science project was initiated on the basis of positive experiences of the chemistry teachers, who were almost for 15 years productively cooperating with the researchers at several research institutions.

Table 11



The growth of the number of students is constant due to the fact that at school, the same teachers are teaching chemistry for almost 12 years and the team approach was agreed upon 8 years ago. As Table 7 shows, chemistry school final exam grades are always above the national average grades.

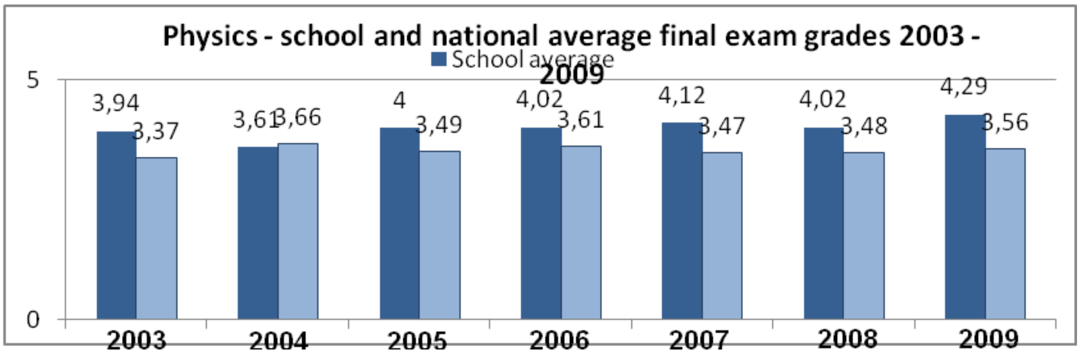
Table 12



Students' achievements are improving every year compared to the national average grade; this is important considering the fact that the number of students in the chemistry final course is increasing.

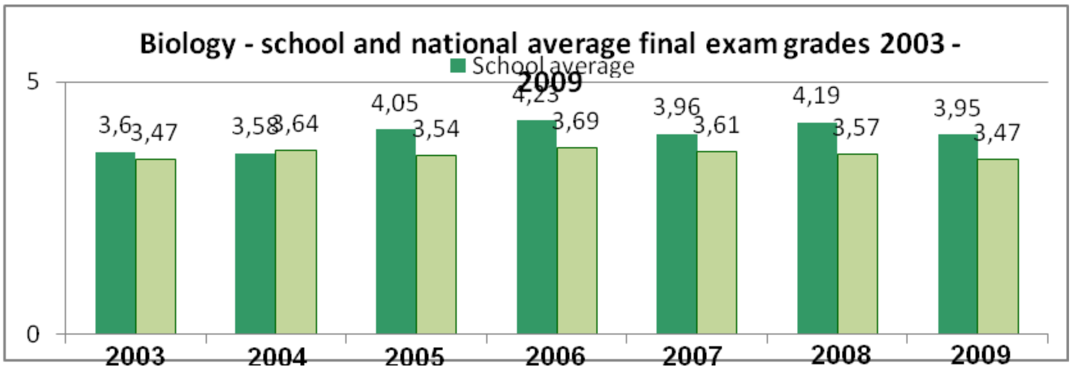
The physics final exam population and matura results (Table 8) show similar tendencies as in chemistry. Encouraged by positive experiences, more and more "academically weaker" students are taking chemistry and physics as their optional final exam subject.

Table 13



Although the biology average grades at the final exam are also very high (Table 9), the number of the candidates is much smaller and thus less relevant to this study.

Table 14



CONCLUSIONS

Implementing student-centered inquiry based science teaching in higher secondary schools is identified as an important goal by educational professional organizations; however it is rarely put into practice. As mentioned above, at Gimnazija Vič an efficient model has been developed how to embed inquiry based science learning into the school/subject curricula. The school results clearly indicate that inquiery based science learning and possibilities to work and learn under the supervision of researchers positively influence the better quality of students' knowledge. We believe that as a consequence of the project, in 2010, a significant growth in the number of students taking science subjects as their optional final exam subjects is noticed. We would like to emphasize that more and more "academically weaker" students are taking part in these courses.

Although the project was initially ment to be limited to the "science classes" only, encouraged by results, this effective way of inquiry based science learning was introduced in every classs - at the school level. This model will be presented and evaluated also in other Slovenian higher secondary schools.

Through the project, teachers were and still are improving their teaching strategies and didactic approaches, their science content knowledge and by this they also build up their competencies. A full co-operation of researchers from universities of pure and applied sciences, research institutions and industrial laboratories with teachers was established.

Some difficulties in these cooperations originate from the lack of possibility for formal agreements based on financial support, which provides the materials and the time needed for the menthorship of the students' projects. The main issue seems to be a complete lack of incentives and systemic support on the national level which causes problems of planning longterm activities.

These activities have a strong impact on school development; Gimnazija Vič is considered as an outstanding school in science subjects on national level. Our students take part in young researchers competitions, competitions in science subjects knowledge and achieve great results on national and international level. Last but not least, a positive feedback information is given on our students' knowledge from the faculties of pure and applied sciences, medicine, pharmacy…

Popularization of science and introducing young people to the important field of research in science and technology has an important positive impact also on choosing their studies in this field. Since students' choice of the optional final exam subjects is directly related to their choice of studies, we expect the students' generation 2010 to enroll on the studies at the faculties of pure and applied sciences, pharmacy… and other studies in the field of science and technology to a much greater extent than the average Slovenian population. Further investigation will be focused on the improvement of the model that has been developed. The impact of the links of the school with the researchers and industry will be explored, how it brings added value to students' knowledge and how it helps them make decisions on their studies and future jobs.

ACKNOWLEDGEMENTS

We would like to render our thanks for all the help, advices and explanations to the researchers at the Faculty of Chemistry and Chemical Technology, Faculty of Mathematics and

Physics, Faculty of Electrical Engineering and Biotechnical Faculty of University of Ljubljana who were patient enough to be supervisors to our students. Our special thanks goes to the researchers at the School of Environmental Sciences of University of Nova Gorica and to the researchers at the National Institute of Chemistry, the Jožef Stefan Institute and the Slovenian National Building and Civil Engineering Institute who presented us some of their work and enabled our students to use their laboratories and equipment. We would like to give our thanks also to the headmistress of Gimnazija Vič, MSc. Alenka Krapež, who enabled us to carry out this research and provided us with the data needed.

SOCIO-CULTURAL & HUMAN VALUES, SCIENCE & TECHNOLOGY, AND ASSESSMENT: AN IMPOSSIBLE MIX?

Graham Orpwood

York University, Toronto, Canada
gorpwood@edu.yorku.ca

ABSTRACT

An emphasis on science, technology, society and environment (STSE) has become a part of science and technology curricula in an increasing number of countries over the past decade. This has challenged science and technology educators to rethink their teaching methods to address socio-cultural and human values in ways that had never been considered in the past. Teachers and students have had to address issues where knowledge and values interact in complex ways, where knowledge from a variety of disciplines is involved, and where new skills of deliberation and analysis are called for. However, as has been the case in previous "curriculum revolutions", assessment methods have been slow to catch up with changes in curriculum and teaching. This time, as assessment has become ever more important in most countries, the lack of adequate assessment methods threatens to derail the entire movement. This presentation outlines this dilemma, illustrates it with concrete examples, and suggests some ways forward.

Keywords: *STSE, values, assessment, validity, politics*

BACKGROUND

Two trends have been of increasing importance to many countries in recent years. The first has been the development of the curriculum to include not only knowledge of subject disciplines, and the skills associated with each discipline, but also understanding of the role this knowledge plays in the personal and public lives of individuals and societies. The second trend has seen the growing use of assessment – particularly international assessments (such as TIMSS and PISA) – as indicators of the effectiveness of schools and educational systems.

This paper argues that these two trends are on a collision course and that, unless educators can move rapidly and creatively to design new and appropriate methods of assessment, the government-sponsored trend towards more accountability-motivated assessments will overcome the academic and professionally sponsored trend towards addressing the relationship of socio-cultural and human values with science and technology.

CURRICULUM TRENDS

I have argued elsewhere (Orpwood, 2001) that changes in the science curriculum over the past 100 years can be seen as a sequence of revolutions and new paradigms (Kuhn, 1962). Continuously, the *content* of the science curriculum – "what" should be taught and learned – is developing and changing and debates over such content change are part and parcel of what can be described as "normal curriculum change".

Overlaying this normal curriculum change, however, have been two periods of what can be thought of as "curriculum revolutions" where the very *purposes and goals* of the science curriculum have been changed. Like the paradigm shifts Kuhn invented to explain the growth of science, these curriculum revolutions fundamentally changed the way that the science curriculum content should be taught and learned. They also signalled radical changes in curriculum policy and also textbooks, curriculum debate and research. Roberts

(2010) in an in-depth analysis of competing visions of scientific literacy, has talked of these as changes of “curriculum policy image.”

The first revolution began in the late 1950s and early 1960s when the aim of the science curriculum moved from a focus on science content for its own sake to include attention to the nature and processes of science. This was the period during which major projects funded (in the US) by the National Science Foundation and (in the UK) by the Nuffield Foundation attempted to redirect the teaching of science.

The second period of revolutionary change began in the late 1980s and early 1990s and added the emphasis on science, technology, society and the environment (STSE). Once again, the science curriculum was fundamentally transformed and made relevant not only to those who would be future scientists but also to future citizens and to those who were entering the world of work. Once again, science literacy was redefined, teacher education transformed, textbooks rewritten, and new agendas for research developed. This revolution took place at different times in different countries and in some places, is only now beginning to occur.

This is where Socio-cultural and Human Values (SHV) began to play a new and important role in the science curriculum. Once we began to see science and technology not just as disciplines of knowledge, or as systems of intellectual and professional inquiry, but also as having significant impact on practical decision-making both private and public, then SHV became closely entwined with science and technology. In the public sphere, issues involving energy, the environment, the economy, and appropriate limits to technological development all command attention. And in the area of private decision-making, the use of cars or public transit, and issues of nutrition and health are but two of the ways in which science and technology interact with SHV in the lives of individual citizens. The challenge of this latest curriculum revolution is to teach young people how to address these issues and to help them develop understanding of the roles science and technology play, both as sources of problems and sources of solutions.

However, throughout the past 50 years, as these two revolutions have changed much in science education, assessment has developed at a much slower rate. The first significant performance assessments – matching the emphasis on skills and processes that was fundamental to the first curriculum revolution in the 1960s – did not appear until the early 1980s in England (APU, 1983) and it was not until the late 1990s before performance assessment became relatively common in North America. Indeed, such assessments are still only now making their way into many countries for the first time.

Performance assessments – where students are given a practical scientific or technological task to accomplish and their skills at inquiry or design are observed and evaluated – are still not endorsed by many assessment specialists as they are hard to design, expensive to implement, and complex to score. The first round of the Third International Mathematics and Science Study (TIMSS), for example, included a performance assessment component. It was initially required for all countries wishing to participate in TIMSS; then, as the project developed, it became optional, and finally its results were published separately a full year after the reports of the written tests (Harmon et al. 1997). Performance assessment was subsequently dropped entirely from later iterations of TIMSS.

Assessments appropriate for the second curriculum revolution – the trend towards incorporating SHV into the teaching of science and technology – have yet to be developed on a large scale. Over the years, a variety of projects incorporating an emphasis on Science, Technology, Society and the Environment (STSE) have appeared throughout the world (Solomon & Aikenhead, 1994). Glen Aikenhead (2006) describes how two main approaches to assessment have been used in these projects: one is a traditional quantitative type of assessment and the other has been a more qualitative or “interpretive” approach to understanding students' knowledge. He adds that "emphasis in science education research has clearly shifted to interpretive studies" (p. 92). While such interpretive studies are clearly valuable in probing students thinking as they deal with issues involving science, technology and SHV (and therefore in evaluating the projects themselves), they cannot meet the demands of formal assessments required by educational systems. There are notable exceptions (two of which we shall review later) but these cases are far fewer than the "curriculum talk" in the journals might suggest.

On the international front, TIMSS tried and (in my view) largely failed to develop an assessment that was both a valid and reliable quantitative measure of science literacy. PISA has made more progress, though Fensham (2007), Sjoberg (2007) and others have made cogent, critical comments on the validity and success of this initiative also. Yet the international prominence of both of these studies has had significant political impact in many countries.

In summary, while the science curriculum in many countries is reaching forward to embrace Socio-cultural and Human Values (SHV) and to enable young people to understand the impact of science and technology on their lives, assessment in science education is largely looking back to an earlier age when the goals of science education were focused on knowledge of the disciplines, for the purpose of preparing young people for science at university. This might not matter, if assessment was not of great importance (both to students and schools) but this is also changing. So I will now turn to examine the second trend: the growth and change of the uses of assessment in education.

ASSESSMENT TRENDS

Assessment of student achievement has always been an important part of the educational scene but, in recent years, we have seen remarkable growth, both in the amount of assessment activity and in the variety of its purposes. This has led to observers analyzing these purposes and commenting on the conflicts arising when many players – each with their own agenda – undertake it. Some years ago, I noted the failure to resolve this diversity of purpose within the TIMSS assessment of science literacy (Orpwood, 2000). More recently, Gordon Stobart (2008) describes how examinations at the end of compulsory schooling began as a relatively straightforward system for certifying individual students and admitting them to postsecondary education but have since morphed into systems of school accountability involving "league tables" based on the proportions of students obtaining high grades. Stobart concludes with what he calls his Principle of Managerial Creep: "*As assessment purposes multiply, the more managerial the purpose, the more dominant its role*" (Stobart, 2008, p.15).

Now for managerial purposes, the overriding criterion for a good assessment (apart from its cost) is that it be reliable. Reliability in testing means high levels of precision, fairness and reproducibility. Since students, schools and countries are being compared with each other (and sometimes also with themselves over time), it is essential that the measures that form the basis for these comparisons be absolutely reliable. Much effort is therefore expended in national and international assessments to ensure this reliability: pretesting of items to determine their psychometric characteristics, elimination of items that do not seem to "fit" the item analysis model being used, careful training of markers to ensure consistency in marking for items that require subjective assessment, and so on. At the end of the day, the test may not measure precisely what it intended to measure but whatever is being measured is being measured very, very accurately.

By contrast, the curriculum developer and the teacher in the classroom, who are developing or using assessment for learning, are less interested in the reliability of there assessment (at least in a strict psychometric sense) and much more concerned for its validity: "Does the assessment correspond to the aims and content of the curriculum?" The (UK) 21st Century Science web site expresses the point well:

> As in all aspects of science learning, assessment is crucially important because it makes teaching and learning objectives clearer than anything else does. This is not simply the observation that 'teachers teach to the test'. It is the deeper point that any statement about learning objectives has to be operationalised in order to pin it down. We have to say what observable action by the student, perhaps in response to a task we set them, will count as evidence that they have achieved the learning we want them to achieve. (21st Century Science, 2008)

Both validity and reliability are important criteria of good assessments, of course. But for managerially-motivated assessment, reliability will always trump validity and for learning-motivated assessment, validity will override reliability. The problem is that as we look around the world at the assessments that command the most political attention and financial support, they are those of the first category. I have indicated elsewhere (Orpwood, 2007a) that I believe that this conflict poses serious threats to the future of this curriculum emphasis but that facing the threats requires both political and conceptual action.

DIMENSIONS OF TEST VALIDITY

"What counts as evidence of learning" is the key validity-related question that curriculum specialists and teachers are concerned about. As I have already noted above, this question is only now beginning to receive answers in relation to the second science curriculum revolution. Part of the reason for this is that for science education that incorporates socio-cultural and human values (SHV), or an emphasis on science, technology, society and the environment (STSE), the question resolves itself into three sub-questions:

- What counts as learning?
- What counts as evidence?
- Does this evidence of learning count for all stakeholders?

The first of these questions is necessary as the types of learning in curricula where SHV are integrated with Science and Technology are more complex than usual and require careful clarification before questions of evidence can be considered. Responding to these two questions constitutes the normal process of establishing the concept validity of an assessment. But my professional experience suggests that we need to add a third question that involves establishing the level of acceptance of the evidence of learning among the various stakeholders of the assessment.

Two Stories

I will illustrate these questions by reference to two stories, both true, one drawn from my own experience in developing science test items for TIMSS, and the other from the reports of colleagues in Alberta, Canada about the development of new science curriculum policy.

Developing TIMSS Assessment Items

During the early 1990s, as science coordinator of TIMSS, I worked with a science expert group, the national research coordinators (from participating countries), my opposite number in mathematics, and TIMSS technical and management colleagues to assemble the science portion of the TIMSS tests. A full account of this process appears in Orpwood & Garden (1998) but here I want to highlight the three broad criteria used to select items. We aimed for validity (basing our item selection on a blueprint developed from Schmidt's (1997) analysis of curricula of participating nations). Reliability was established through pretesting all items and the use of IRT scaling to obtain item characteristics and aid final item selection and test construction.

But, additionally, all items were scrutinized by the research coordinators from the 45 participating countries and, while no country had a veto over the inclusion of any given item, this review process was important as the tests were assembled. Many good items, especially those that touched on SHV or on links between science, technology and society were eliminated during this process. Some of these were dropped because of cultural sensitivities – for example, an item dealing with human reproduction was judged to be inappropriate by some Islamic countries. More often, however, the comment was made: "Our students would never be asked a question like that." Some countries were more particular than others about the items they wanted to see eliminated but I had no doubt that items incorporating societal values were among the most frequent casualties. The results of this process form part of the background to some of Peter Fensham's (2007) critical judgments about TIMSS, judgments with which I concur.

A few items in the Science Literacy component of the TIMSS tests addressed topics that included SHV but most were very conventional, calling for simple analysis of data about a scenario set in a social context. Only one question was of the variety where there was no one right answer – at least, no one answer was equally correct in all countries – and there was considerable resistance to its inclusion. It dealt with the social consequences of technological change and, not surprisingly, the results emerging from this item from across the participating countries proved fascinating to analyse (Bartley and Orpwood, 2005).

Developing Science Curriculum Policy in Alberta

My second illustration is from Canada, where the movement towards incorporating an STSE emphasis into science education – the second curriculum revolution noted earlier – was given significant boost by the publication of the Science Council of Canada's (1984) report on science in Canadian schools. The Canadian constitution designates education as the exclusive responsibility of the provinces and one of the first provinces to embrace this new direction was Alberta. In the late 1980s, the introduction of this emphasis into senior secondary school courses, with its inevitable incorporation of SHV, was attacked savagely by senior members of the science and engineering community with such phrases as "social science masquerading as science" and "dumbing down" of high school education (Byfield, 1989; Blades, 1994; Panwar & Hoddinott, 1995). After periods of "consultation" by a ministerial task force, the emphasis was softened significantly and the crisis averted. Fensham (1998) also reports Australian examples of where the STSE emphasis was "marginalized" as a result of criticism from influential members of the scientific community.

The power of the academic community cannot be underestimated in this regard. They control access to university science – determining which school-based credentials qualify a candidate for university admission. They also control the postsecondary scientific education of future science teachers – many of whom continue to hold such professors with high respect. Students aspiring to enter university, and teachers with responsibility for preparing them, disregard such pronouncements at their peril. The politics of academic approval are therefore likely to trump any efforts to incorporate an emphasis on STSE into the curriculum or assessment.

Summary: Two Dimensions of Validity

Figure 1 summarises the argument of the paper to this point. I am suggesting that there are two dimensions to the validity of assessments, the conceptual dimension, about which much has been written in the assessment literature, and the political dimension, which has been much less systematically studied.

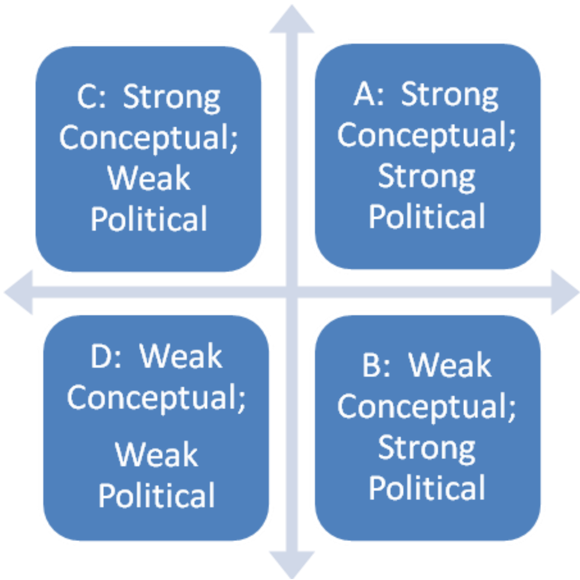

Figure 1. Conceptual and Political Dimensions of Validity

In an ideal world, the validity of assessments is both conceptually and politically strong (quadrant A). That is: We have identified the learnings we are trying to measure and the evidence for them, and, in addition, there is good support among the stakeholders of the assessment for both of these. Achieving a quadrant A assessment is the goal for all developers. Sadly, this goal is very hard to achieve as experience has shown.

Too easily, assessments can slide towards Quadrant B or C. Quadrant B represents those that are weak conceptually though strong politically: TIMSS is a good example, where the assessment may be a poor reflection of the aims of the curriculum in many countries but where it nonetheless commands strong political support among participating nations. Many national examination systems have failed to keep up with intended changes in direction in the curriculum and also fall in Quadrant B. In China, for example, new curricula have embraced an STSE emphasis and yet the examination system in some provinces has not kept pace with the intended change (Orpwood, 2007b). The result has been a significant drag on real curriculum change

Quadrant C represents the reverse problem – where an assessment matches the curriculum well but where only weak support among key stakeholders, notably members of the academic science community, has resulted in few students risking their future by taking courses whose assessments may have limited currency. The Alberta experience described above is an example. Quadrant D represents assessments that have neither strong conceptual nor political validity and is usually an empty quadrant.

AIMING FOR SUCCESS

Using the graphical device shown in Figure 1, we can consider what can easily happen with assessments that try to incorporate SHV. First, it is often hard – particularly in a formal assessment (as distinct from a teacher's informal classroom assessment) – to identify precisely those learnings that we want to measure and what would constitute good evidence for those learnings. Thus conceptual validity is difficult to achieve. Second, issues that touch on socio-cultural and human values are often controversial and thus their inclusion in an assessment can provoke criticism and resistance. These make political validity hard to achieve as well. Often the easiest response is one of retreat to the safe area of assessment of students' science knowledge.

Some curriculum and assessment initiatives have *not* retreated in this fashion and these give cause for optimism that the attainment of quadrant A for curricula and assessments, which integrate SHV into science and technology education is possible. The two examples described here illustrate two ways in which values have been integrated into science and technology education. They both have "official" status within their respective jurisdictions and therefore both have achieved at least a degree of political validity.

Science 30 in Alberta

The first example comes once again from the province of Alberta (Canada) though it is of more recent date than the story told earlier. Science 30 is a course taken by students in their final year of secondary school who do not intend to specialize in the more specific science disciplines at the postsecondary level. The curriculum handbook for parents makes its overall philosophy for science education clear:

> The aim of the senior high school science program is to help students attain the scientific awareness needed to be effective members of society (Alberta Education, 2009a).

This philosophy is further elaborated in the on-line program guide:

> … a science program must present science in a meaningful context – providing opportunities for students to explore the process of science, its applications and implications, and to examine related technological problems and issues. By doing so, students become aware of the role of science in responding to social and cultural change and in meeting needs for a sustainable environment, economy and society. (Alberta Education, 2007)

Further, the goals of the Science 20 and Science 30 courses include the following:

- Enable students to use science and technology to acquire new knowledge and solve problems so that they may improve the quality of their lives and the lives of others
- Prepare students to critically address science-related societal, economic, ethical and environmental issues.

It is interesting that, while at no point is the word "values" found in these documents, it is evident from the foregoing that the Science 30 course is intended that students grapple with highly value-laden socio-scientific issues.

Let us therefore turn to the assessment – at least the formal "diploma examination" set by Alberta Education – designed to assess students' attainment of these goals. The Science 30 examination is in two parts, a written paper and a machine-scored paper (Alberta Education, 2009b). The machine scored paper is divided into sections by topic and each section comprises multiple choice and numerical response questions in each topic area. The section on energy – of major importance and some controversy in Alberta as well as elsewhere – is fairly typical of the entire examination. The section is headed by the following statement:

> Space science may have an increasing role in shaping future societies, including the development of technologies to produce energy.

The section contains 14 questions on scientific topics related to energy, such as electromagnetic radiation, nuclear reactions, and energy conversions. Most of the questions are intended to elicit evidence of students' understanding of the science of energy itself and their ability to make appropriate calculations in this area. One multiple-choice question relates to environmental risk: it is headed by the statement: *"An environmental risk associated with burning coal is the production of acid rain"* and asks for evidence of students' knowledge about the effects of acid rain. Other sections of the examination, similarly *make reference* to issues of SHV but refrain from calling upon students to show evidence of their ability to deal with them.

The written paper, by contrast, calls for students to address the same range of topics but be able to develop conclusions and make arguments based on data provided in the paper and examine both sides of complex questions. For example, the first section provides data on vehicle emissions for cars and trucks using both petroleum diesel and biodiesel fuels. From this data, the students are asked to state one effect on either human health or the environment associated with a particular emission (this calls for some recall of what they had been taught but also the ability to make connections with the provided data). The paper goes on to ask the students to explain how the given data support the view that "biodiesel is an environmentally friendly fuel" *and* how the data contradict this view. In this way, the students are being assessed on their understanding of how science interacts with value-laden human, social, and political issues. Overall, therefore, the Alberta assessment lives up to its intended goals and demonstrates both conceptual and political validity (quadrant A in the chart above).

Twenty-First Century Science (UK)

I referred earlier to the 21st Century Science project, a British initiative of the University of York and the Nuffield Foundation. As was the case with the Alberta curriculum, the 21st Century Science web site speaks to its intention of fostering scientific literacy:

> The model offers all students the chance to develop the scientific literacy that they need to play a full part in a modern democratic society where science and technology play a key role in shaping our lives - as active and informed citizens.(21st Century Science, 2008) – Rationale

The overall program is quite complex with a variety of courses designed for students having differing career or postsecondary goals.

Information about the assessment takes the form of past examination papers which are available on the web site of OCR, the examination board associated with the project. Reviewing these examination papers suggests a very different approach than can be seen in the Alberta papers. The paper I reviewed was based on three short articles on socio-scientific topics, which the students had taken home to read and think about. Then the examination paper (which was also divided into three sections, each based on one article) had the students respond to a series of questions about each topic.

One topic for example was entitled "Is PVC safe for our children?" The preliminary article had concerned itself with the the uses of PVC, the use of plasticizers to change the properties of the PVC, scientific research on the effects of plasticizers, and the risks – particularly to children's health – associated with plasticizers. The questions followed a similar pattern and moved from early questions calling for evidence that the students had understood the article, and were familiar with scientific methods of investigation to later questions that addressed the more complex issues of risk and benefit. Here students were asked to think about the issues from more than one standpoint and to give evidence *for and against* a claim.

This assessment drew a clear line between matters on which there could be right (and wrong) answers and questions (such as the last one) where the values-laden issue was (politically and ethically) much less clear. The evidence being sought from the students was their ability to sort through complex issues and to consider more than one perspective. Both of these assessments, one from Canada and one from the UK also demonstrate that it is possible to assess the sorts of knowledge and abilities to be expected of an "active and informed citizen." Both clearly belong in quadrant A of the chart.

CONCLUDING COMMENTS

This paper has argued that in considering the assessment of science curricula that incorporate socio-cultural and human values (SHV), we must take into account both conceptual and political aspects of validity. This is very hard to do in practice and relatively few have been as successful as these two examples.

I have also tried to answer the question in my title: *Are SHV, science and technology, and assessment an impossible mix?* My response has to be a qualified "No"; not an impossible mix, but still quite a rare one and always one that is hard to achieve. This conclusion also suggests that two key lessons can be learned.

(1) If we wish to successfully implement a science curriculum rich in SHV, we cannot ignore assessment issues. To do so or to use traditional assessments almost guarantees that the SHV component of the curriculum will be reduced to a motivational frill and not the key emphasis;
(2) If we try create an assessment that is true to the spirit of an SHV-rich science curriculum, then we must take into account the political as well as the conceptual aspects of validity. Failure to do this risks that an otherwise good curriculum and assessment may be marginalized by the "powers that be" and ignored by teachers and students. Taking the politics of assessment into consideration and working hard to create a broadly acceptable assessment appears to be the only route to success.

While many educators are understandably nervous of politics and researchers of studying the politics of curriculum and assessment, we need more such studies if we are to learn lessons from their success and failure. Then we can become more adept at integrating SHV adequately into science and technology assessments.

STUDENTS' DISCUSSION IN SUSTAINABLE DEVELOPMENT
- BASED ON THEIR OWN ECOLOGICAL FOOTPRINT

ABSTRACT

Within Education for Sustainable Development (ESD) various skills and knowledge are discussed, both in policy documents and in research reports. Therefore the aim of this study is to investigate what skills and knowledge students actually use in discussions related to sustainable development. Groups of students were observed when they worked with a task about Ecological footprints, within the subject *Science studies*. The subject is mandatory in all programmes in the upper secondary school and is about science for citizenship. Group discussions were audio recorded and transcribed.

A content analysis was performed and thereafter a specific search for utterances which could be interpreted as critical thinking, conflicts of interests or ability to use cause and consequences.

Results show that the students have ideas about “environmentally friendly behaviour” and shows interest in equity issues. There was some science in the discussions, for example food-chains and population growth. The skills critical thinking, cause and consequence reasoning and ability to see conflicts of interests were not frequently used.

The students were surprised and unaware of their own and Sweden’s ecological footprints. The most common conflicts of interests were between their lifestyle and environmental impact.

Keywords: *Science education, Education for Sustainable Development (ESD), classroom observation, Ecological footprints, upper secondary school*

INTRODUCTION

Sustainable development and education for sustainable development are abstract and complex concepts that societies and schools around the world are expected to work with. The World Commission on Environment and Development report *Our Common Future* (1987) is often referenced to when sustainable development shall be defined. Their definition is *"development which meets the needs of the present, without compromising the ability of future generations to meet their own needs".*

There are policy documents and reports that discuss the role of education within sustainable development. Learning is seen as an important part in the quest towards sustainability (Scott & Gough, 2003). Education for sustainable development should be based on an integrated approach to environmental, societal and economic development. The individual learner should have the knowledge, values and skills to be an active, democratic and responsible citizen (Baltic 21E). This raises questions about what knowledge and what skills are needed to become an active, democratic and responsible citizen. UN Decade of Education for Sustainable Development 2005-2014 provides the following six characteristics for ESD: Interdisciplinary and holistic learning, value based, critical thinking instead of memorizing, methodological pluralism, participation decision and locally relevant information (UNESCO 2009).

Sweden is unique in that all students have to attend a science course in the upper secondary school irrespective of what programme they choose. The Swedish curriculum for the upper secondary school (National Agency for Education 2000) states that this subject *Science studies* is an interdisciplinary subject in which scientific questions can be viewed from different perspectives. The aim is to provide scientific knowledge required to take a stand on issues that are important to the individual and the society, such as sustainable development and energy issues. The subject is about science education for citizenship and future profession.

Our research interest is science education for citizenship in the upper secondary school in *Science studies.* Science for citizenship is partly about developing people's ability to promote their opinion in socio-scientific issues. To do this they need knowledge *in* science and *about* science – nature of science. Both in science education research and in research about education for sustainable development there are discussions about how students develop knowledge, values and skills to be an active, democratic and responsible citizen. We want to bring these two areas together and study what will be learned when science education takes its starting point in sustainable development.

BACKGROUND

Today there is a consensus that science should be a compulsory school subject but the curriculum is mainly written by scientists who perceive school science as part of further studies in science (Osborne & Dillon, 2008). For a long time science education in school has been characterized by an academic tradition which emphasizes solid ground, the right answers, science structure and science skills (Swedish Research Council, 2005).

In literature review of the concept scientific literacy/science literacy, Roberts (2007) describes one vision about science education that is based on situations with a partially scientific content. Socio-scientific issues are scientific related situations that students may face as citizens, in which other considerations than pure science needs to be done. These issues can promote democratic citizenship through science education. Socio-scientific issues are relevant and can bridge school science and students´ lived experiences (Sadler, Barab & Scott, 2007).

The traditional, science-oriented approach to environmental education has been criticized for leading to knowledge about the existence of environmental problems but not leading to action competence. It has not been capable of addressing the social and societal perspectives of these questions (Jensen & Schnack, 1997). Many of the political and moral problems confronting society today are posed by the advance of science and technology. Osborn and Dillon (2008) discuss that these dilemmas require a solution which involves a combination of assessment of risk and uncertainty, a consideration of the economic benefits and values, and some strengths and limits of science. To understand the role of science in such dilemmas students need to be educated to become critical consumers of scientific knowledge.

The Swedish National Agency for Education also finds that the three-dimensional definition of sustainable development by integrating economic, social and environmental factors has not yet been implemented in the Swedish education (SOU 2004:104).

According to the syllabus for *Science studies*, students shall learn science in contexts of socio-scientific issues such as sustainable development. It seems as though topics with social relevance are more motivating for the students. On the other hand, they are often complex, and therefore more difficult to understand (Aikenhead, 2006). Research has revealed that such issues challenge students' rational, social and emotional skills. However, several problematic factors are identified, such as that the students can easily be distracted when they are working with multifaceted issues where the outcome is often not clear (Zeidler, Sadler, Simmons & Howes, 2005). This means that there might be a conflict between the dilemma-based issues' potential for motivating students and for making them focus on the scientific content.

Critical thinking and ability to see complexity are important skills in ESD. Critical thinking is described as reflective and evaluative thinking which necessarily leads to substantiated judgements (Mogensen, 1997). He argues that in the democratic perspective it is important to become a critical thinker. To question critically, and act according to the answers founded, is contributing to the development of a more democratic and sustainable society.

Many different areas of knowledge are involved in ESD and the issues are often value based and have an ethical dimension. Such issues often include conflicts of interest between individuals or groups of people (Jensen & Schnack, 1997; Lundegård, 2007). To be able to identify conflicts of interest and to use the cause and consequence thinking can be seen as some criteria for complex reasoning (Ekborg, 2005).

Environmental and development issues are taught in different ways in schools. A study in Sweden identified three different selective traditions within environmental education. These are the *fact-based* tradition, the *normative* tradition and the *pluralistic* tradition (Östman, 2003). In the fact-based tradition, environmental issues are treated as problems that can be solved by more knowledge. In the normative tradition, the aim of the education is to support an environmentally friendly transformation of society. The pluralistic approach is characterized by a striving to promote different perspectives and values when dealing with problems concerning the future world (Öhman, 2008). About half of the teachers in Sweden are teaching in sustainable development in accordance with the normative tradition (Östman, 2003). There have also been critical discussions about education *for* sustainable development, that it will lead to indoctrination and that the students will not learn skills to think for themselves (Jickling, 1992).

AIM

The aim of this study is to investigate what skills and knowledge students actually use in discussions related to sustainable development. We used the example of Ecological footprints. Our special focus is on the science content.

The research questions are:
What do the students talk about in a discussion about Ecological footprints?
What kind of conflicts of interests do the students bring up in discussions about Ecological footprints?
Do the students use causes and consequences and apply critical thinking in their discussions?

RESEARCH DESIGN AND METHODOLOGY

This is an exploratory study in the sense that the research questions are open and there is a need to learn from the participants in the study (Creswell, 2005). The students were observed when they worked in groups with a task about Ecological footprints. The group discussions were audio recorded and transcribed verbatim. We have followed the Swedish Research Council's ethical rules (Codex n.d.).

Participants

The study has been performed in an upper secondary school in a town in northern Sweden. The students were in their first year and attended the course *Science studies*. Before this study started the students had studied ecology and energy and we came in when the content about sustainable development was to be introduced. The 24 students, 4 male and 20 female – attended two programmes: a social science programme and a programme to become hairdressers.

Education purpose and design

We followed the class during the first two lessons related to sustainable development. The purpose of the two lessons was to create interest and to make connections between students lived lives and sustainable development. It also gave the students the opportunity to see the complexity in these issues and be aware of the global dimensions. The Ecological footprint is a measure of the demand human activity puts on the biosphere. It measures the amount of biologically productive land and water area required to produce all the resources an individual, population, or activity consumes, and to absorb the waste they generate, given prevailing technology and resource management practices (so called global hectares) (Ewing et al., 2008). To understand the concept you need science and it becomes obvious that these issues are global.

During the first lesson students, in pairs, calculated their own Ecological footprint. The students used the WWF website (2009) to convert their consumption and waste-production within four categories, food, home, transport and waste into global hectares. During the second lesson the students discussed their results in small groups. There were six groups of four students each.

The design of the small group discussions were that the students were given the opportunity to have an open discussion about thoughts that the footprint calculation lesson created. When the spontaneous discussions ended they were given some questions and claims to discuss, like;

- Globally we use resources corresponding to 1,4 planets, how can that be possible?
- Some countries Ecological footprints per capita.
- Meat- and paper consumption for the richest 20% of the population on earth.

Data analysis

The analysis is based on the group discussions from the second lesson. A content analysis was performed (Bergström & Boreus, 2005). The content of the discussions was categorized into different categories. After several readings we found the following categories, the three dimensions of sustainable development –ecological, social and economical dimension. In the social dimension politics, equity issues, health and working conditions were included. We also found the categories environmentally friendly behaviour and personal experiences.
A specific search for utterances which could be interpreted as conflicts of interests, ability to use cause and consequence reasoning and critical thinking was also performed. When students put two interests against each other we have taken that as a conflict of interests. Both if students have shown awareness about the conflicts on a structural level for example between economy and environment and conflicts on an individual level were identified. Within the individual level we included both when students expressed that their lifestyle was

threatened and conflicts between different groups of individuals. When students have reflected, evaluated or asked questions about a statement we have taken that as indicators of critical thinking

RESULTS

Overall the discussions are moving from food, transports, energy use and waste- production when the students present their results. The students relate to “environmentally friendly behaviour” which they have ideas about. It was also the most common content of the discussions. When we look at the three different dimensions that often are used when we describe sustainable development; ecological, economical and social dimension we can see that all dimensions are discussed more or less in different groups. Personal experiences were also discussed (table 1).

Table 1. Content of the group discussions. Y means that it was in the discussion three times or more, ¤ twice or less, - means that it was not in the discussions.

Content / Group number	Ecology/ Science	Economy	Social			Environmentally friendly behaviour	Personal experience
			Equity	Politics	Other		
1	Y	Y ¤	-	Y ¤	Y ¤	Y	-
2	-	Y	Y	Y	Y ¤	Y	Y
3	Y	-	Y	Y ¤	-	Y	-
4	Y	Y ¤	Y	-	Y ¤	Y	Y
5	Y	-	Y ¤	-	-	Y	Y ¤
6	Y ¤	-	Y ¤	-	-	Y	Y ¤

In four groups the students were unaware of their own and/or Sweden’s big ecological footprints and were surprised when they found out. The students showed interest in equity issues in five out of six groups (social dimension).

The most common science content that was discussed was about food-chains, food-webs and population growth. Other comments were about physiology, natural selection and matter flows. The students used science as statements to tell what nature is like, e.g. that nature is trying to keep things in balance. They did not use science or scientific skills as a way to make progress in the discussions or create understanding about science issues. For example when they got information that we use resources corresponding to 1,4 globes, they did not use their knowledge about different natural resources to find out how or if that could be possible.

The most common content in the discussions was “environmentally friendly behaviour”. Below is an example of a discussion about this in one of the groups:

Sofia: - *It would be good if everybody recycle their waste.*
Gun: - *Buy ecological stuff.*

Helen: - *Stop going by car*
Sofia: - *Walk or take the bus*

To see the complexity in the discussions, we searched for the above mentioned conflicts of interest (table 2). The most common identified conflicts of interest were between their lifestyle and environmental impact (see excerpt below) and economy and environment. Conflicts of interest between different groups of people and between animals and humans were only mentioned twice each.

Erika: - *ehh, we could live on what we really need*
Tina: - *not like this...all the unnecessary stuff and so*
Jens: - *how boring life would be*

Another way to see complexity is the use of cause and consequence reasoning (table 2). Most common was how economy influences human behaviour and how human population growth will affect the environment. Other examples were about how society creates opportunities for people to live "environmentally friendly", for example makes it easy to go by bus or create opportunities to sort their garbage. Overall cause and consequence reasoning was not a skill used very often.

In the discussion with Sara, Tina and Anita (group 4) there are examples of critical thinking. This skill was used in three groups but not very often (table 2).

Sara: - *but look, if we live at 1, 4 (globes), we still live at one (globe)*
Tina: - *Yes, everything is still..*
Sara: - *Who has calculated this, I wonder.*
Tina: - *Yes*
Sara: - *We still have enough food*
Tina: - *Yes, all*
Sara: - *Don't we? There is still a lot of food.*
Anita: - *Maybe Elise's grandchildren can't have any food.*
Tina: - *Yes but what, these poor. They have to get it better. It would be better if it was more equal so that*
Everybody starts talking
Sara: - *We have to climb down and they have to get up*
Tina: - *Yes, exactly*
Sara: - *Yes but what, it is still the same result.*
Tina: - *Yes but*
Sara: - *They can't mean that we all shall live as*
Silence

Table 2. Skills used in the group discussions. Y means that it was in the discussion three times or more, ¤ two times or less, - means that it was not in the discussions.

Skill	critical thinking	cause and consequence	conflicts of interests				
			lifestyle - environment	economy - environment	humans - humans	humans - animal	other
1	-	Y	Y	-	-	Y ¤	-
2	Y ¤	Y	Y ¤	Y	Y ¤	-	Y ¤
3	Y ¤	Y ¤	-	-	-	-	-
4	Y	Y	Y ¤	Y ¤	-	-	-
5	-	-	-	-	-	Y ¤	-
6	-	Y ¤	Y ¤	-	-	-	-

DISCUSSION

The task with calculating their own Ecological footprint and then discussing the results created opportunities for the students to integrate the social, economic and ecological dimension in sustainable development. In the discussions, students focused on environmentally friendly behaviour. When they found out about the equity issues in this task, the interest increased and those issues were discussed. The ecological/science dimension was not discussed much and it was not in a reflective way. The question is whether the students learned any science. At least they never discussed and asked questions about the science content. This study indicates that when sustainable development issues are learned in school, the ethical dimension creates most interest. The conclusion that Aikenhead (2006) discussed that topics with social relevance are motivating for the students but also are complex and therefore more difficult to understand is also indicated in this study. In science education we have a challenge in inquiry based teaching about sustainable development, to create tasks where the students can integrate the different dimensions but also focus on and learn science.

The students demonstrated knowledge about environmentally friendly behaviour. The different behaviours were not questioned during the discussions. In the discussions there is a consensus about “a good behaviour”. The results of this study indicate that in this school situation the students thought that they should relate to “environmentally friendly behaviour” and did not use skills as critical thinking, cause and consequence reasoning and identified conflicts of interests that much. If it is the normative teaching tradition in environmental education that causes this is impossible to say. These issues are often discussed in a normative way in school (Östman, 2003) but also in media. It shows that it is important how we construct tasks and that the classroom discourse encourages critical thinking.

According to curriculum and policy documents we shall teach and learn for sustainable development. This study indicates that in these issues we have to plan very carefully so that the teaching encourage critical thinking and not only teach the students norms surrounding it. We also have to give the students opportunities to find out and learn about conflicts of interests on a structural and societal level and not only on the individual level.

Future direction

It is interesting how complex issues within sustainable development affect the learning. Do students manage to learn both about the complexity between the different dimensions and learn science in sustainable development issues? Is the ethical dimension so interesting so that it overshadows the other dimensions or does it enhance learning? How students use and learn skills as critical thinking to make progress in their learning is also important to know more about. This will be studied further.

ACCESSING CULTURAL HERITAGE THROUGH A HISTORY AND PHILOSOPHY IN SCIENCE TEACHING (HIPST) PROJECT ON TEMPERATURE

John Oversby

University of Reading, UK

ABSTRACT

Promotion of engagement with science learning at the adolescent stage is a major challenge for science educators. The European History and Philosophy in Science Teaching Project has focused on providing resources for supporting historical and philosophical approaches. This paper describes the theoretical underpinning for a project on measurement of temperature for 11 year old students in UK schools. The topic lends itself to a phenomenological approach suitable for novice learners in school, and avoids the more advanced thermodynamic treatment that would be beyond these students, while maintaining elements of rigour. Development of the module involved close collaboration between the researcher and two of the teachers, through discussion of the lessons, and subsequent feedback and reflection on the evidence collected. Data collected suggests that the teachers made substantial progress in their understanding of the place of History and Philosophy of Science in science teaching, partly through the innovative methods employed in the class of student newspapers and student play scripts. The students were hampered in their progress by problems in providing appropriate laboratory equipment and by poor literacy for some of them. Nevertheless, significant progress was made by a majority in understanding principles of measurement in the context of temperature. An associated wiki (a web-site that allows easy creation and editing of inter-linked pages using a simple web browser) was created and had some modest use by the project participants.

Keywords: *History, philosophy, temperature, engagement*

INTRODUCTION AND BACKGROUND

The 30 month, 8 country, EU History and Philosophy in Science Teaching (HIPST) project was established in February 2008. The UK part of the project has focused on three themes. The themes were: a) the role of creating measuring instruments in concept construction using the topic of temperature; b) creating an idealized concept from real and imperfect instances, using the topic of acidity; c) the special place of modeling in chemistry through paper tools, using the topics of chemical formulae and chemical equations. The theme described in this paper is Measurement in the context of temperature. Temperature was chosen because, in England, it is a traditional part of the National Curriculum at this age, and because it relates well to particle ideas of matter. Under Cultural Understanding, the same National Curriculum requires pupils to 'recognise that modern science has its roots in many different societies and cultures, and draws on a variety of valid approaches to scientific practice'. The science education community's values are embedded, often implicitly, in its intended curricula. For example, the Science National Curriculum in England for 11 – 14 year olds (QCDA, 2009) states that: 'Pupils learn how knowledge and understanding in science are rooted in evidence. They discover how scientific ideas contribute to technological change – affecting industry, business and medicine and improving quality of life. They trace the development of science worldwide and recognise its cultural significance.' Similar statements are made in the curricula of other countries. The American Association for Advancement of Science (Project 2061) (AAAS, 1993, 2009) notes: 'The images that many people have of science and how it works are often distorted. The myths and stereotypes that young people have about science are not dispelled when science teaching focuses narrowly on the laws, concepts, and theories of science. Hence, the study of science as a way of knowing needs to be made explicit in the curriculum,' with development of some of the history to exemplify what should be done. Evidence from the ROSE (nd) project suggests that learners value human aspects of science.

THE HIPST PROJECT

HIPST presents an effort by science education scholars to promote science education by the development of materials for teaching and learning science which are informed by the history and philosophy of science (HPS).' (Höttecke, 2008) The project members agreed that the place of History and Philosophy of science in schools was both extremely under-represented and presented in a dry fashion, contributing to disengagement with school science. Their understanding of the ROSE (n.d.) evidence was that school science, in western countries at least, was devoid of humanity. Research (e.g. Williams, 2002) indicated that history of science was presented in textbooks in the form of 'heroes and villains' with little indication of the human side of the scientists other than that they were born and died, and discovered something important in their lives. These discoveries were rarely set in the context of the international community of scientists working at the time, or of their discussions and access to particular pieces of equipment. There was little recognition that many worked on their own, sponsored by rich aristocrats or by industrial philanthropists, or were themselves wealthy. Others worked in institutional laboratories, in universities that were creating departments of research and teaching in the sciences, with a coterie of colleagues benefiting from their academic research leadership. Indeed, there is little evidence in textbooks that the scientists had working lives full of frustration and excitement, who met from time to time, sometimes in fledgling learned scientific societies. In short, the historical depiction in scientific textbooks can be described as sterile, and usually brief.

Rather more worryingly, the philosophical base in textbooks is almost non-existent, being relegated to short discussions of a fairly naïve view of the nature of science that claims there is one scientific method.

I have devoted some time to material in textbooks since these appear to be a major resource for teachers in learning about appropriate pedagogy. An absence of space devoted to HPS in textbooks would suggest a similar position in practical teaching.

The HIPST project members are convinced, in the first place, that inclusion of the History of Science in everyday teaching is necessary as part of the process of humanizing science. They are also aware that published scientific papers are reductions of the scientific process that omit dead-end thinking, alternative ideas that were conceived and then discarded after discussion and review, and challenges in apparatus construction and measurement. It seems that textbooks take this a step further and largely restrict their content to well-established content and ways of thinking. So, their second aim was to provide resources that would provide a more authentic view of how science progressed in the past, using historical narrative resources such as biographies and autobiographies, and contemporary accounts of the stories of ideas construction. This might include replicating historical scientific experiments. Their third aim was to use historical data, or data from replicate experiments, to recreate the scientific discoveries, and to notice the challenges that faced the original researchers. In this way, not least because the data collection and analysis problems have already been recorded in the historical literature, they can more easily support the learners in understanding how science works from the past. The HIPST project members were strongly aware of the challenge of making judgments of past scientific work from the perspective of our present knowledge. This is known as whiggishness. Their fourth aim was to avoid this trap in producing and trialling materials. The fifth aim was to develop teachers' views about the nature of science, perhaps through discussion of the trial materials, since teachers' personal subject knowledge is a great influence on teaching and learning in the classroom. The evidence available to the HIPST project suggested that historical examples can provide clearer learning about the nature of science than more contemporary examples. Finally, the sixth aim was to develop pupils' views about the nature of science through these examples.

The particular specialism of the UK part of HIPST was that it was mainly focused on chemistry, and on learners aged between 11 and 14 for two of the themes. At this stage, learning of the sciences tends to be largely phenomenological and descriptive, especially in chemistry. The focus of other HISPT projects in the other countries was mainly directed towards older learning, with many programmes in quantitative physics. HIPST in the UK offered an opportunity to tackle the challenge of engaging younger learners with HPS materials. Historical background material in sciences tends to be more obviously related to older learners, so a major question was whether there was a suitable topic for those in the 11 14 age range. This topic had to be related to the existing curriculum.

The topic of temperature is one such topic. The history of the concept of temperature is well documented (e.g. Chang, 2004) and there are many web sites devoted to this history. Unusually among measurements, temperature is independent of the three base units, mass, distance and time. Chang (2004) convinces us that devising methods of measuring temperature helped scientists in the past to clarify their understanding of the concept. This phenomenological approach makes it amenable as a topic for young learners, particularly as a route for introducing the philosophy of measurement. Issues such as standardization, calibration, sensitivity, and accuracy are central to temperature measurement. I faced the choice of where to stop the study. Fortunately, the absence of a direct link with the three base units makes the issue of absolute temperature measurement a distinct break from the phenomenological approach. Absolute temperature is only precisely defined in terms of an ideal gas, and that makes it inaccessible to these young learners.

This work is also concerned with the teachers as learners. The matter of personal subject knowledge for science teachers is complex. The teachers involved in this work declared their limited prior knowledge of specific historical knowledge, and their even more limited prior knowledge of specific philosophy of science. Therefore, this work was intended to improve both those aspects of the teachers' knowledge.

METHODS

Research questions

1. What are the purposes of including History and Philosophy of Science (HPS) in school curricula? What HPS is embedded in curricula?

2. What is presently known about the effect of HPS teaching in schools?

3. How do teachers respond to an explicit HPS teaching programme?

4. How do young learners respond to an explicit HPS teaching programme?

1 and 2: These were mainly desk studies supplemented by meetings with teachers.

3: Three teachers undertook to teach a module on temperature to explore the effect of measuring on validating, and developing the reliability and accuracy of scientific equipment. The teachers took part in discussions by email, face to face conversations that were recorded by hand, and one by constructing a reflection log

4: Teachers in two schools volunteered to trial materials with a total of 150 pupils aged 11-12 years old. Data collection included open-ended written questions, recording of learning in notebooks, field observations by the author, debriefing discussions by the author that include reports agreed with the teachers, pupil play scripts about a historical event. In each of the lessons, the teachers planned small interventions by the researcher (co-teaching) to demonstrate some aspects of teaching this innovative material. These requested interventions amounted to 5 or so minutes in each of the lessons. As the project developed, the researcher produced one or two page newspapers for the pupils, incorporating historical evidence, anonymised pupil conversations, and some optional puzzles for the pupils to carry out in their own time. The newspapers also incorporated specially produced short play scripts to explain historical events. The researcher also produced staff newspapers to summarise training sessions and to share with other science colleagues.

DESCRIPTION OF THE EXPERIMENTAL MODULE

The following table focuses on the outcomes after trialling and evaluation over two cycles. Underlined text indicates modifications after the trials.

Table 1. Description of module on temperature

Lesson outline	Learning objectives	Teacher guidance	Assessment opportunities
1. a) Weber's Three Bowls activity b) Introduction to liquid in glass thermometer as a practical method of determining temperature c) Exploring determination of upper fixed point. Thermometer placed at various points above and in boiling water. Accept liquid in glass thermometer and explore issue of where and how to measure the upper fixed point. Focus on need for measurement.	a) Critical evaluation of skin as thermometer. Folklore of everyday measuring temperature e.g. elbow in bath water for young children. Need for more reliable method. b) Explore issues of where to measure the upper fixed point, and the need to specify standard conditions. Specifying conditions in using measuring equipment is part of improving validity, reliability and accuracy. c) Understanding the meaning of thermometric property, in the context of a liquid in glass thermometer. d) At a higher level, to understand that the thermometric property may not measure temperature, but we accept that it is the best we can have.	a) Weber's experiment is traditional. Here the emphasis is on the need for carefully specified standards in providing for high quality equipment. Using the human body is simply unreliable in determining temperature. b) In the first trial, the 11 year old pupils were very clear that the boiling point of water was 100ºC, not least because that was what they had been told at Primary School. This activity will fail if all it does is to say, for example, place the thermometer at point x, because that was where it read 100ºC. It might be easier for pupils to appreciate if they were asked to put themselves in Celsius' place, and a bit of history from the teacher may be helpful here.	a) Diagram sketch with thought bubbles to give pupil thinking (e.g. feels hot/cold in the middle bowl!). Use of standard and reliability in account to show explanation of the underlined terms. Diagram sketch with annotated temperatures at different levels. Include a written discussion to show pupil thinking to indicate explanation of standardisation/ calibration, in measurement, and idea of specified conditions to ensure reliability focusing on underlined words. The scientific ideas here are measurement (see paper in wiki), reliability. These are fundamental to processes of collecting scientific data. Write a clear set of instructions to specify the exact conditions.
2. Exploration of the gas thermometer as the most valid and reliable practical thermometer. a) Pressure increases when a gas is warmed up. Explain in terms of particles moving faster and hitting the walls more often. With finger over the end, dip a syringe half full of air in a bowl of warm water and feel the pressure. b) Measuring the pressure. Use a giant water (coloured) manometer (arms at least 2 m long), and a boiling tube fitted with stopper and connecting tube. The	a) Understanding meanings of validity, reliability and accuracy through focusing on historical approaches to determination of a practical thermometer. Applying particle knowledge to effect of temperature on pressure of a gas. This is known as Gay-Lussac's Law: Gay-Lussac's other law, discovered in 1802, states that: *The pressure of a fixed mass and fixed volume of a gas is directly proportional to the gas's temperature.* From http://en.wikipedia.org/wiki/Gay-Lussac's_Law	The issue with liquid in glass thermometers is the uneven expansion of both the liquid and the glass with temperature (although how that was determined is another story!) In practice, for mercury thermometers, the uneven expansion of the glass compensates quite well for the uneven expansion of the mercury, quite fortuitous. It was the search for a uniformly variable thermometric material that led scientists to the constant volume gas thermometer. The constant volume gas thermometer turned out to be the most valid, reliable	a) An annotated sketch (bubbles) of a syringe in warm water with particles moving, to explain increase in pressure. An annotated particle picture of a manometer to show how it indicates pressure An annotated diagram to show how different levels relate to the ice point and steam point in a manometer. An annotated diagram with calibration marks to show how the scale is constructed. Explain the meaning of accuracy, reliability and validity (this last one will be very hard) in the context of the gas thermometer.

water in the manometer arms should be half way up to start. Cool the open boiling tube in ice water to let the temperature settle. Connect gently to manometer. The levels should be the same on both sides. This is the ice point calibration level. Now warm the boiling tube with hands and watch the levels change. Discuss in terms if faster moving particles increasing the pressure. Now place boiling tube in boiling water (steam point) and mark upper fixed point. Finally, place boiling tube in hands and estimate the temperature from the levels. Discuss how to calculate and the notion of a scale. c) Estimate the temperature to reach 12 m (one atmosphere). d) Discuss the idea of negative temperature in terms of water levels. e) Estimate the temperature (negative) to reach zero pressure (boiling pint tube higher) i.e. absolute zero.	b) Understanding the meaning of thermometric property, in the context of a gas thermometer, i.e. pressure. c) To know about the efforts scientists made to reduce errors (to improve both accuracy and reliability). This includes reducing the volume of air at an unknown temperature (short and narrow tube), and to measure the temperature of the air in this tube to allow for it. d) To be able to use the gas thermometer to detect different temperatures. e) To be able to calibrate the gas thermometer at the ice point and stem point (if possible) f) To be able to determine an intermediate temperature by interpolation. g) To be able to extrapolate to absolute zero.	and accurate practical thermometer available. In practice, the air should be dried, and mercury would be used for the manometer to avoid water vapour. Additionally, since we are interested in the temperature of the air in the container, the connecting tubes would be kept as short as possible, and as narrow as possible to minimise the volume of air at a different temperature. A correction for this external volume would be made, using a mercury-in-glass thermometer for its temperature as being good enough. It is, after all, only a small correction! The gas thermometer is likely to be a new piece of equipment for many teachers. I have provided some pictures of various types below *(in original text*). The thermometric property is the pressure of the gas.	b) Explain the meanings of interpolation and extrapolation.
3. Reflection corner. The purpose of this activity is to promote some reflections by the pupils into historical scientific progress concerning temperature. We are using pupil plays to share first ideas about the problems of standardising. These plays can be prepared in advance and then shared in small groups. The debate can be recorded by two pupil scribes, to provide a record of the discussion. The group could be self-monitoring, rather than having a chair.	a) To be able to give reasons for standardising in measurement, such as improving validity, reliability and accuracy. b) To be able to recount, in modern terms, historical efforts to standardise measuring temperature. c) To be able to reflect on the role of scientists in determining temperature.	Formative assessment of reflection is a challenge in this section. Firstly, there is experimental work to be done on using plays for assessment purposes. This is rather innovative! Secondly, there is the use of debate to put forward claims, to examine evidence and to come to conclusions. This is not new, and is part of argumentation, but it has not been based on written plays before.	a) Short play to recount problems of fixing the steam point. b) Debate to check pupil understanding of process of standardizing. c) Evidence to show understanding of validity, reliability and accuracy developments in science.

RESULTS

Research question 1: What are the purposes of including History and Philosophy of Science (HPS) in school curricula? What HPS is embedded in curricula?

Williams (2002) surveyed the history of science in textbooks in England in 1999, following the integration of history and philosophy of science into the mainstream school science curriculum. He notes that, history of science is often relegated to brief and sterile 'heroes and villains' descriptions.

Pedagogical innovations that have engaged most pupils have included producing play scripts of scientific stories, and newspapers written in simple language. Using pupil work as a source of material for newspapers has also been an important innovation. The pupil newspapers have also served as a valuable source of information for the teachers. Some new activities have been developed: lack of equipment in schools and skills of technicians was a barrier, and has led to specific training for the latter. The project has noted that underlying understanding of basic concepts, such as particle ideas, needs to be secure for the full potential to be achieved. Many pupils have produced extra work, and focused on working with the new pedagogy.

Höttecke (2009) in his ESERA paper acknowledged the importance of History and Philosophy of Science towards school teaching, and the dearth of research about HPS teaching in schools. He also reported the lack of curriculum resources for HPS teaching in schools.

Under Cultural Understanding, the National Curriculum in England requires pupils to 'recognise that modern science has its roots in many different societies and cultures, and draws on a variety of valid approaches to scientific practice' The same national Curriculum goes on to say that pupils in lower secondary schools should 'explore contemporary and historical scientific developments and how they have been communicated'. The National Curriculum does not prescribe how this should be carried out. HPS is implicit in the model of How Science Works, since historical data can provide valuable experience for learners to analyse and interpret. Historical data also provides alternative interpretations for learners to critique as part f learning how to evaluate data they collect themselves in investigations.

HIPST has accepted a range of purposes for HPS teaching in schools. These are documented on the HIPST web site and a brief reference to them is given here. The original paper contains details of the references.

'Contextualized Learning: Curriculum developers all over Europe have stressed the role of **context for science learning**. From a student perspective a context enriches science learning with meaning and shows how science is inextricable merged with society, economy, ecology and culture. Therefore, historical reflections of the role and character of science are not restricted to perspectives on the past, but contribute to an **understanding of the interaction of science and society** in general.

Advancement of problem solving skills: International comparative studies like PISA have shown that competences of **problem solving** are deficient in many European countries. History and philosophy of science highlight the process of science in a rich cultural context and open up ways to science teaching and learning which is jointly oriented to the process of science as well as to the process of learning. The history of science is full of opportunities to study the problem solving activity of real scientists in authentic situations.

Inquiry learning within historical settings: Inquiry learning fosters the learning of scientific concepts. Inquiry learning encourages students to develop their own **strategies of problem solving**. The history of science provides a wide range of resources for inquiry learning in this sense.

Reconstruction of historical experiments: If students work with reconstructions of historical experiments they will be engaged with authentic problems, build small scientific communities, which share their knowledge and skills or demarcate themselves from those of other student-communities.

Promotion of a better comprehension of scientific concepts: This argument recognizes that **scientific concepts** can be formulated more intelligibly in their historical context of discovery than in a schematic and systematised way of modern interpretations.

Supporting conceptual growth: Research indicates that the study of **historical concepts can help students to develop their own concepts towards a scientific comprehension**.

Showing science as European cultural heritage: Students become aware of the **different national contributions to science**.

Learning about the nature of science: In a Delphi study (Osborne *et al*., 2003) have shown experts of science education, science, history, philosophy, and sociology of science to generally agree that **learning about the nature of science** belongs to the central objectives of science education.

Explicit reflection on the nature of science: Research has shown that even inquiry-oriented teaching does not necessarily lead to a better comprehension of the nature of science. Several studies recommend **explicit reflection on the nature of science** which is an integral part of teaching the history and philosophy of science in our view.

Developing citizenship in a science and knowledge society: The nature-of-science-argument promotes the view that **active citizenship in democratic decision-making processes** requires knowledge about what science means as political decision-making increasingly depends on scientific expertise.

History as a tool for teaching about the nature of science: Several studies indicate that epistemological beliefs about knowledge and knowledge acquisition affect attitudes and processes of learning. Research and case studies of teaching practice have shown the **effectiveness of history-oriented teaching** in order to learn about the nature of science.

Science as a human endeavour: Science appears less abstract and gets the **character of a human endeavour**. This argument touches the problem of public recognition of science as systematic and inhuman.

Supporting authentic images of science and scientists: The inclusion of historical case studies in science teaching provides realistic **images of science** as process and **images of scientists** themselves.

Promoting girls' attitudes towards science: Research indicates that especially **female students benefit** from the changing character of science as an open inquiry and from the appearance of scientific knowledge as progressive and changeable.'

Research question 2: What is presently known about the effect of HPS teaching in schools?

This has been answered in the response to research question 1.

Research question 3: How do teachers respond to an explicit HPS teaching programme?

The draft activities were produced by a working group composed of the HE researcher and a group of 6 teachers over a period of 6 months. The working group met four times and communicated by email in the intervening time. The draft activities were then subject to trials, over a three week period in two schools with three teachers. As each teacher trialled the materials in lessons, the material was modified and the modified materials, with the justification, passed to the next teacher. In this way, a three cycle development programme took place.

One teacher took part in a structured interview after the teaching trial that was recorded in the form of brief notes. A second teacher wrote a similar report based on the same questions. One teacher was a specialist in chemistry and the other in physics. They were in different schools in the same local authority. Both teachers mentioned their initial interest in the project as part of their professional development. Neither teacher had studied philosophy of science prior to the project. Both teachers had a very modest knowledge of some historical material. Each trial was initiated by three training sessions, one to one with each teacher, each lasting one hour. During these training sessions the purposes and details of the activities were discussed, and often led to further modification of the lesson plans. Each session was subject to a face to face debriefing of between 30 and 60 minutes immediately following the lesson, with notes made and discussed by the researcher with the teacher. Further discussion took place by email and by telephone. An associated multi-layered wiki (a web-site that allows easy creation and editing of inter-linked pages using a simple web browser) was created and had some modest use by the project participants. The wiki is at www.ukhipstinstruments.wikispaces.com.

The first teacher reported some modest misunderstanding in the purpose of the activities despite the training sessions. On reflection, this may have been caused by the teacher and researcher providing insufficient time for discussion of that aspect in the training. Perhaps it was assumed it was obvious after only a short discussion time. Both teachers mentioned the successful outcome of the Three Bowls activity, which they had done before. The activity in determining the steam point in boiling water was mentioned as one that was carried out reasonably, but they felt was not as successful in learning as they would have liked, partly because they had not focused on the issue of measuring temperature, as just reported. Both teachers mentioned the gas thermometers with manometers. This lesson had proved to be problematic in terms of equipment. There were only one or two Bourdon pressure gauges in each school. The teachers had expected there to be a few more from their own knowledge but were surprised by how few there were when they asked the technicians. They believed there would be enough for one for each of four groups. The project group also chose to use water manometers for determining pressure (mercury manometers are forbidden on safety grounds, and this was known in advance). The water manometers had to be 2 m long in order to accommodate the changes in pressure in going from 0ºC to 100ºC. Construction of such manometers was new to the laboratory technicians and the final solution in each case was, probably, unsatisfactory, especially in the light of their limited materials to work with. Both teachers reported some difficulties in making sense of the philosophical purposes of the activities, and, therefore, in promoting the learning of the pupils in that respect, even though this had been thoroughly discussed in advance. The teachers appreciated the newspapers written for the pupils as learning tools for themselves. They both indicated very strongly a willingness to go for another trial the following year.

Research question 4: How do young learners respond to an explicit HPS teaching programme?

As expected, the young learners were tolerant towards the lessons as judged by their behaviour and questions. Their class notes and discussions indicated strong engagement with the activities, not least in attempting to measure the boiling temperature of water when they were not quite sure about the historical problems in doing this. In the second trial, many of the pupils were seen reading some of the newspapers, although the teacher commented that the language may have been challenging for many. They were impressed by the story of Gmelin's 1830 expedition across Siberia at the behest of Catherine the Great. Some of them took part in an optional activity to produce a play script to show their understanding. The play scripts produced by some of them showed that they understood that the issue was the problem of the mercury freezing in determining the lowest temperature reached using a mercury thermometer. They were aware that solid and liquid mercury could shrink at different rates. There was some extra effort put in by some pupils in producing play scripts, as well as in conducting surveys at home about the meaning of temperature. This is an indication that the pedagogy used in this project strongly engaged these pupils, not least because the teachers reported that the pupils rarely undertook extra work of any kind.

CONCLUSIONS AND IMPLICATIONS

The materials produced for the first theme have been trialled and reviewed. The results so far have established the strength of a collaborative two cycle approach, involving a researcher from Higher Education, and practicing teachers in schools, producing relevant and robust resources for subject knowledge and the Nature of Science. The project has been successful in these respects:

1. The resources provided are innovative in a number of ways:

a) the use of web sites with optional information and opportunity for blogs, discussion and teachers to create their own pages and upload their own files is innovative;

b) the use of newspapers for revealing history of science, in pupil-level language, is unusual for both pupils and teachers;

c) recreating historical experiments is unusual in these teachers' experience

d) the use of play scripts for recording and assessing learning is unusual.

The project represents work in progress. Nevertheless, there are some clear implication from the project to date:

1. More resources for teaching HPS are needed and have been provided by the project.
2. Curriculum materials that mesh with the curriculum are more likely to be readily accepted.

3. Teachers need more time in preparation and in evaluation if curriculum change is to be securely embedded in their practice.
4. Some innovative pedagogies such as producing play scripts, and newspapers, can support increased engagement by pupils, and by teachers who also use them as a source of personal knowledge.
5. Developing curriculum resources for such a novel area demands considerable time for discussion with the teachers, and better access to appropriate equipment.

ABSTRACT

The theory of biological evolution is essential in order to understand the diversity of living organisms, although it is still controversial in certain social groups. We reported a piece of research carried out in order to comprehend the acceptance or rejection of biological evolution by Brazilian students of two different groups from Tangará da Serra, in the Amazonian region, the groups were: High School freshperson students and Undergraduate students seeking a Biology degree. The information was collected with questionnaires using Likert scales. Two hundred and ninety-four (294) questionnaires were filled out by high school freshperson students and one hundred and fifty-nine (159) questionnaires were filled out by undergraduate students seeking a Biology degree. Students' scientific knowledge and religious beliefs were significantly correlated. In both groups, it was observed that attitudes in opposition to evolutionary orientations were influenced by religion and it is more evident in females, who proved to be more committed to religious activities.

Keywords: *Teaching of biology, evolution, religion.*

INTRODUCTION

The tension between understanding and acceptance of the evolutionary theory has been widely discussed among researchers of science studies (Alters and Alters, 2001; Hokayem and Boujaoude, 2008). Some point towards student immaturity to understand this theory; others speculate that the professors have not approached this theme in an adequate manner to motivate student learning; and a third group shows that, in some cases, students simply reject evolution due to religious explanations constructed in their family context and which account for the origins and development of living organisms (Alters, 2005; Sinatra et.al., 2003; Cobern, 1994). Therefore, in this work, we attempted to comprehend the acceptance and rejection of evolutionary theories by students from Tangará da Serra city in Mato Grosso, Brazil, from consulting two groups: 1) high school freshperson students; 2) undergraduate students seeking a Biology degree.

MATERIAL AND METHODS

The information was collected with questionnaires using Likert scales. A scale can be defined as a collection of items used to determine the distribution of a given characteristic in a population. It is a group of values that represent qualities, for example, behaviors, objects and interests (Ary; Jacobs and Razavieh, 1972). The scale is also called an additive scale since the sum of a group of items discusses a latent matter. Ary, Jacobs and Razavieh (1972), comment that the additive method comprises the presentation of a number of positive and negative phrases about an attitude object. Each one of the phrases admits to five responses, whereby the individuals indicate how much they "strongly believe", "believe", "are undecided", "disbelieve", or "strongly disbelieve" in the affirmation. It is important to mention that an original Likert scale permits a neutral option and comprises alternatives in odd numbers. A scale that does not present this number of categories is also called a "Likert-like scale". Some researchers have elaborated scales consisting of only four options so as to ensure that the responder takes a stand in the matter. For Hill and Hill (2004), there is no rule concerning the number of options; however, the second form of inquiring is normally linked to the search for more intimate and delicate responses.

In the research carried out in the scope of elementary education, the questions elaborated were adapted from the ROSE questionnaire – Relevance of Science Education. This instrument was developed in the University of Oslo (Norway) by the Department of Teacher Education and School Development (Faculty of Education) and aims to verify the importance of science and technology learning and the various factors that influence the motivation to learn science and technology related contents from the perspective of 15 year students of different countries. This questionnaire was elaborated using closed questions and fixed alternatives in a Likert-like scale of four options. In Brazil, the translation/adequation of the ROSE questionnaire respected the structure and order of questions and five questions were added on the themes: biological evolution and religion. According to Schreiner and Sjoberg (2004), this format is simpler compared to others when constructing phrases as well as responding to them. However, it presents a greater assurance in comparative studies. These questionnaires were applied to 294 recently registered high school students in a large school in Tangará da Serra - MT, being that these students came from 37 elementary schools in the region. These students presented a mean age of 15 years (32.2% students below 15 years; 49.0% aged 15 years; and 18.8% above 15 years) and a majority of them were females (58.4%). In relation to religion, a majority manifested themselves as participants of the catholic church (66.9%); in second place were the evangelics with 23.2%; 8.32% denied any religion and 1.42% were grouped in the category of other religious beliefs.

One hundred and fifty-nine (159) questionnaires were applied to higher education students of Biological Sciences of a state university also in Tangará da Serra, using Likert-like scales with five alternatives. In this case, neutral responses were permitted. In the questionnaires these responses were represented by the option "Neither agree nor disagree" and appears as *indifferent* (I) in the results. Schreiner and Sjoberg (2004) explained that the neutral category has been excluded from the analyses since it normally generates ambiguous responses. Mostly, the responders do not consider the neutral category to be an intermediate between the extremes: they could therefore choose this option due to lack of knowledge in the subject, failure to understand the matter, lack of motivation or a refusal to respond. Some works have also shown that there is a greater tendency to choose this option compared to the others. For one to show neutrality about a topic can be easier than siding.

In the case of the university students, the neutral response was permitted as long as they presented maturity and knowledge to understand the meaning of neutrality. During application of the questionnaires, they were oriented not to respond to questions they did not understand, so as to avoid ambiguities. The majority of the responders were females (74.8%), aged between 19 and 21 years. The majority of students manifested themselves as Catholics (51%); 19.7% stated they believed in God, but were not part of any religion; 16.6% identified themselves as protestants; 5.7% responded that they were atheist or agnostic and 3.2% referred other religions. The analyses were carried out after processing using statistical software from the description of frequencies, spearman correlation tests and nonparametric analyses of variance.

RESULTS AND DISCUSSION

In general, 80.2% of the undergraduate student interviewees understand that evolution is important in their daily life and 70.8% agree that removal of evolution teachings from the school curriculum would be a disadvantage. Although 74% believe that the evolutionary theories present important steps in the right direction, only 46.7% have the same opinion when the discussion focuses on human beings, 40.9% of the students showed that they do recognize conflict between learning evolution and their cultures. On the contrary, 35% believe that such theories are opposed to their cultural values (table 1).

Table 1: Attitudes of some Brazilian university students concerning Biological Evolution

"On evolutionary theories studied in school or in the university [...]"	TD*	D	I	A	TA
The evolutionary theory can contain some imprecisions and open questions, but signifies a great step in the right direction	1.9%	7.8%	16.2%	58.4%	15.6%
The evolutionary theory is a combination of worthless assumptions for my life	32.1%	48.1%	10.9%	3.2%	5.8%
The evolutionary theory is contrary to cultural values that are important for me	11.7%	29.2%	24.0%	21.4%	13.6%
The exclusion of teaching Biological Evolution from the syllabus could be a step backward	8.9%	10.8%	18.5%	38.9%	22.9%
I believe the explanations offered by the evolutionary theories on the expense of the origin of human beings	10.5%	15.1%	27.6%	38.8%	7.9%

***TD – Totally Disagree; D – Disagree; I – Indifferent; A – Agree; TA – Totally Agree;**

The questionnaire was given to undergraduate students who were asked their extent of commitment to religious activities (individual, family and community); their responses varied from *not at all* to *very strongly* committed (figure 1). It is possible to realize that a majority of the university students have a strong or very strong sense of well-being just by participating in religious activities. They mainly develop individual or family religious activities and about half of the students believe that their theological knowledge is significant.

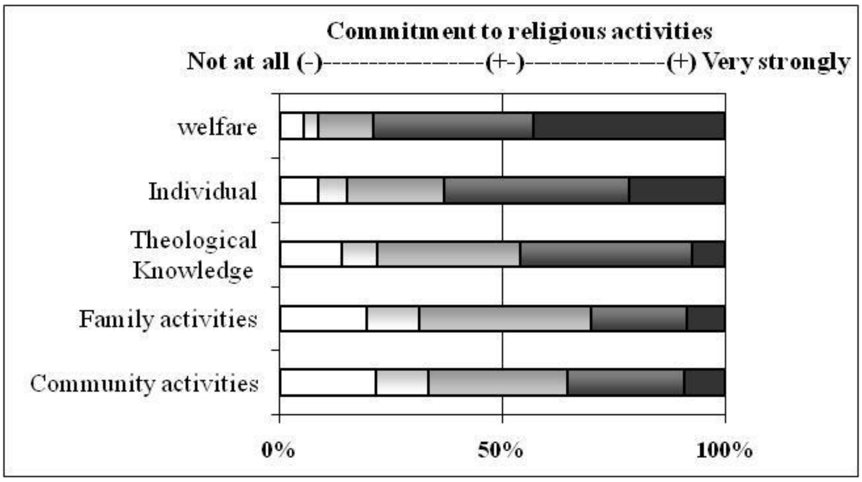

Figure 1. Frequency distribution according to intensity and type of participation of university students in religious activities. Cronbach's Alpha = 0,877

From these answers, it was evident that those who were more committed to religious activities manifested the greatest rejection to evolutionary theories (Spearman's ρ -0.460, sig. 0.01). Among these students were the Evangelics (Kruskal-walis, p=0.004). The females manifested themselves to be more committed to religion when compared to males, considering that they tended to respond *strongly* or *very strongly* committed (Mann-Whitney U, p=0.000).

Similar information was found in the analysis of the high school freshperson students. The difference in participation frequencies in religious activities calls for attention, the females (46.4%) manifested themselves to be more frequent participants in religious activities than the males (29.7%) (Mann-Whitney, p=0.001). Apart from this, the proximity to religion is also mentioned in the question that measured the Tangará da Serra students' attitudes as there was a 72.4% correlation in the item *I am a religious person,* and *one with faith*; and a 74.9% correlation in the component *I understand* and *I believe in religious doctrines and teachings*. Regarding the high school students' attitudes towards biological evolution topics, evolution evidences based on fossil registrations (61.2%), as well as common ancestry (66%) and natural selection (66.5%) are accepted with high concordance levels. Although the concordance levels are low, students tend to accept the components concerning the origin and evolution of the earth (49.7%). After summing the results, we observe rejection sentiments of items referent to the origin and the evolution of human life since 55.3% of the interviewees disagreed with items in this topic.

Table 2: Attitudes of some Brazilian university students concerning Biological Evolution

Item	TD*	D	A	TA	NR
The fossils are an evidence of species that lived in the past and that are currently extinct.	12.2	20.1	27.2	34	6.5
The present animal and plant species originated from species in the past.	12.6	13.6	33.7	32.3	7.8

The Evangelic students also tended to strongly reject evolution, more than the others (Kruskal-Wallis, p=0.005). It was observed that students adopted different attitudes regarding scientific knowledge depending on the association they had established with the religious dogmas. Apart from this, the adolescent females of this group were more intense church goers than the males (chart 1).

Chart 1: Multiple comparison between the mean of religious groups in Tangará da Serra – MT

Evolution	29.63 (±5.59)	26.89 (±7.00)	31.29 (±6.24)	0.002

N=294 α Cronbach= 0.754

In the case of university students, when the variables related to evolutionary tendencies were tested in relation to progression of students in the course, significant results were not obtained. We mention that the syllabus and the pedagogical structures of this course are being re-structured, but it was not possible to obtain more recent data on the matter. It is important to point out that syllabuses in other courses in Brazil present similar characteristics as presented by Goedert (2004).

Goedert (2004) aimed to analyze elements of initial training and teaching practice that contribute to teaching of Biological Evolution. A case study was developed using application of questionnaires, together with seven Biological Science professors of the Federal University of Santa Catarina, who graduated between 1989 and 2000. These professors, based in Florianópolis and São José, presented a five-year mean of experience in Elementary Education and were aged 28 to 35 years.

These professors manifested difficulty in working with evolution perspective in classrooms, especially due to problems associated with initial training. Among the problems leading to these difficulties, they pointed out that what they had learnt about evolution was not sufficient for their post-graduate needs. They also pointed out the disarticulation of evolution perspective from other specific subjects in Biology, as well as the university degree (Goedert, 2004).

Tidon and Lewontin (2004) developed similar considerations to those developed by Goedert (2004) when they pointed out that there was inaccessibility to knowledge on evolution for researchers as well as professors. This shows that the problem is not specific to the university investigated in this research. However, according to the study developed by Tidon and Lewontin (2004), this problem can also reflect on pedagogical activities implemented by these future professors and consequently on their students.

Greene (1981) considered that Western thinking comprised an interaction between religious, philosophical and scientific ideas. He also analyzed the mutual influence between Evolution and Christian thinking, natural theology and social sciences. According to him, the impact generated by evolution ideas in areas like philosophy and religion was much stronger than that in the scientific field.

An example of Greene's observations (1981), scientific and religious knowledge, constructed by investigated students showed this intense relation. In this research, it was observed that the students' points of view concerning evolution were influenced by their religions as well as the degree of commitment to religious activities.

Students who referred a greater proximity with different types of religious activities (individual, family or community) tend to be more distant in terms of evolution orientations, especially the Evangelics. Females were more committed to the religious universe than the males. They also presented the least proximity with the evolution perspective. According to data gathered together with high school students, it is possible to infer that these behaviors have been constituted based on influence of the religious education by the students' families.

Results obtained from the High School students showed that these students accept the evolution evidences based on fossil registration as well as common ancestry and natural selection. However, there was significant rejection of theories concerning the origin and evolution of the earth and human beings. Apart from this, the female adolescents in Tangará da Serra were more frequent church goers than the males. According to Blackwell, Powell and Dukes (2003), it is possible to accept an evolutionary theory with or without a discussion of events in the evolution of *Homo sapiens sapiens*. The authors also asserted that acceptance of the evolutionary theory or its constituent would represent a significant step toward understanding this theory.

Rejection of evolution has been classified in scientific works as a creationist attitude. Although creationism is considered to be a political movement, its bases are embedded in religious values. This political dimension is mainly centered in the United States of America where a number of nongovernmental organizations support anti-evolution actions.

In Brazil, the creationist attitudes are still incipient and currently do not characterize a political movement, like it is in the United States of America. For this reason, in this research, we speak of creationist tendencies, but not of creationist groups since we aim to highlight the influences of some religious attitudes on acceptance and rejection of evolution, without allusion to politically organized creationist groups. However, different motivations to reject the biological theory are found in the attitudes of students of different schooling levels. Alters and Alters (2001) discuss that they can be religious or nonreligious, as well as a combination of both. The results found with elementary education students and high school students point towards the existence of an association between rejection of some topics referent to the evolutionary theory and religious beliefs.

Alters and Alters (2001) described four subgroups within creationist groups: Literalists, Progressives, Theists and the Intelligent Design. According to these authors, many *Progressives*, compared to the Literalists, are more flexible in their beliefs. They understand that biblical texts can be interpreted according to contexts in which they were written. To this group, the Earth was created by supernatural forces, as explained in the biblical texts; however, the creation days described in Genesis can signify time intervals that can reach millions or billions of years. They also consider that humans and other living organisms were created by God, and that Adam and Eve were the first human beings. The divine forces occasionally intervene on Earth, especially in the creation of new organisms (Alters and Alters, 2001).

Theists are characterized by refuting the idea that Evolution occurred without the intervention of supernatural forces. They can be divided into two groups. The first group defends that chance has minimum influence on evolution or it is not altogether existent. The evolutionary theory is conditioned to God’s decision, who guides the whole process. They also denominate themselves as Theistic Evolutionists (Alters and Alters, 2001). The second group understands that the Evolution process involves an authentic random element, but God planned this mechanism while purposely attempting to produce humans. This group is also denominated as Intelligent Design. To some defenders of Intelligent Design, the deviser is not necessarily a biblical divinity, but can be any other type of supernatural or foreign force (Alters and Alters, 2001).

Pagan (2009) presented complementary data about the same university students consulted in Tangará da Serra. He constructed a scale that contained affirmations of creationist orientation from the four perspectives. Analyses of the presented frequencies by items that composed them allows inference that for a majority of the students, creationist tendencies are linked to characteristics of the Progressive and Theistic groups, mainly because three fifths of the students agree on the existence and influence of God on the Universe, as well as on the biblical explanations on the origin of life. However, to this larger group, the Christian Sacred Book is not the maximum authority concerning daily topics.

Sepúlveda (2003) aimed to characterize the strategy used by a group of protestant students, in Biological Sciences Licensure of the State University of Feira de Santana (*Universidade Estadual de Feira de Santana – UEFS)* in Brazil, to associate scientific and religious knowledge. She applied semi-structured interviews to five protestant students of the sixth and last semester of the Biological Sciences Licensure course at *UEFS*. This researcher realized that some students distinguish scientific and religious discussions, using them in their respective contexts. However, they feel the need to learn the scientific perspectives so they can integrate them into their religious beliefs.

To one of the students interviewed by this researcher, scientific knowledge does not bring her satisfaction or comfort considering uncertainties due to the conjectural nature of scientific theories. This is something she finds in biblical literalism owing to the idea of absolute truth (Sepúlveda, 2003).

To Alters (2005), a discovery of why the students reject Evolution and how they feel about this topic can help professors to increase the teaching-learning relationship since rejection is mostly supported by complex cultural fundaments.

The data analyzed by Pagan (2009) identified that less creationist students have more instructed parents. This condition suggests the influence of Higher Education on the re-significance of religious family values, what identifies family as a significant influence on those who decide to consider the Teaching of Evolution. If family can be a strong corroborator for a creationist orientation, not knowledge of evolution itself, but a dynamics of the knowledge constructed during undergraduate studies can be an important factor to reconstruct such values in the home context.

In profiles of university students interviewed by Pagan (2009), the same students consulted in this work, two types of family settings were identified: students who live in a nuclear family setting and those who live alone, with their friends or husbands and wives. Some statistical tests showed that students who live by themselves have a greater proximity with the scientific universe and also with the evolution perspective. Interpretation of this information suggests that students living on their own are less influenced by religious family values since they are not routinely influenced and are more exposed to daily decision-making that increases their chances to develop autonomy.

This analysis seems to indicate that students who separate themselves from religious values can search for new ways of understanding their own human identity, their origins and future perspectives in a discussion that is more compatible with Evolution.

The religious beliefs tend to have an important role in the manner that an individual perceives the theory of biological evolution. In the case of science professors, it can influence the decision to teach or not to teach the theme in classrooms. Alters and Alters (2001) highlight that omission of biological evolution theory is common in North American science syllabuses in all schooling levels, although more frequent in elementary education. It is not different in Brazil since, according to Tidon and Lewontin (2004), biological evolution is normally taught in biology classes, at the end of the 3rd year of high school, fragmented in relation to other discussion themes and disconnected from themes discussed in previous schooling years. Time dedicated to study biological evolution in public schools is insignificant.

While they study the sentiments and worries of future Canadian professors regarding the teaching of biological evolution in elementary schools, Asghar, Wiles and Alters (2007) discuss that future professors accept the theory of biological evolution and intend to include the teaching of this theory in the elementary school syllabuses. However, there is a concern among the professors regarding the acceptance of this theory by students and their parents since the inclusion of evolutionary theory in science can confront the students' religious beliefs. Another concern of the future professors is the impression that their academic formation did not contribute to an adequate understanding of the theory and did not offer a theoretical basis on pedagogical strategies to deal with controversial themes in classrooms.

Opposition towards the theory of biological evolution, common in the conceptions of the future professors as well as those of the high school students, is related to cultural and social environments in which they are inserted. Since the religious beliefs seem to be striking even among the future professors, it is necessary to think how these professionals will intermediate their personal beliefs and teaching of the theory of biological evolution just as it is necessary to think how this science professors will cope with their students' reasons to reject the evolutionary theory, and the cultural context that supports the rejection.

CONCLUSIONS

Rejection of the evolutionary theory due to influence by religious matters is manifested by the interviewed students in elementary as well as higher education. They present a nucleus of religious opinions on the origin of the Earth and human beings, a system of beliefs that accompany the students to classrooms, contradicting scientific knowledge.

The scientific and religious knowledge constructed by the interviewed students were significantly related. It was observed that the contradictory attitudes to evolutionary orientations are influenced by religion and manifest themselves strongly in females, who demonstrated to be more committed to religious activities. In this context, the evolutionary theory seems to be influenced mainly by social and cultural characteristics of the environment in which these students live. In both schooling levels, high school freshperson and undergraduates, the students rejected contents of items which referred to the origin of human beings from evolutionary explanations.

In the two groups that were studied, it was observed that part of the scientific knowledge on the theory of biological evolution was accepted. A possible association between rejection of some aspects of the theory of biological evolution and affinities with religion suggest that the presence of different theories to explain the human existence can interfere with the student's attitude to a theory. In this sense, it seems important that students comprehend how to distinguish epistemological differences between knowledge explaining the origin of the universe and that explaining the origin of life.

Discussions on the nature of science can contribute to understanding processes of construction and manifestation of scientific thinking. However, according to some case studies presented in this work, it is possible to realize that there are contexts in university and elementary courses that still present evolutionary thinking as a body of disconnected concepts to biological thinking. The curriculum offered in the Brazilian Elementary Education favors scientific enunciations, only promoting memorization of facts, rules and scientific theories to the detriment of comprehension that science is a dynamic process, influenced by various factors, mainly, human activities.

A curriculum that favors elucidations about the nature of science is essential for the students to comprehend the distinctions between scientific, religious, cultural and philosophical knowledge, among other knowledge models that aim to explain the world. It is also essential to comprehend that any knowledge is valid in the context in which it is produced, without the need for ranking. They are forms of knowledge with different epistemologies.

These data should be compared in future researches of curriculums of training courses for Biology professors, considering that they do not have a large influence on High School students and future professors.

ABSTRACT

Engaging students in science so that it is meaningful requires science teachers to think 'outside the square'. This is critical given the impending shortage of engineers and physical scientists that is evident in many OECD countries with emerging issues already prevailing in Australia. However, if science teachers are to re-think their pedagogy and update their scientific understanding in a manner that supports student learning they require access to the necessary expertise. This paper outlines a program set up to support secondary science teachers in achieving this goal by allowing them to design school-based projects relevant to the specific needs of their students. By accessing and incorporating expertise outside the school students became more aware of the relevance of science to their lives and better informed about science-related careers. Similarly, science teachers were able to enhance their scientific understanding and skills while exploring a range of mechanisms for engaging their students in science. Most important was the realisation that if teachers are to be agents of change they must be able to access support and expertise *when relevant to their teaching* so that authentic professional learning occurs.

Keywords: *making science meaningful, teacher professional learning, industry engagement*

INTRODUCTION

Within Australia there is much evidence available about the drop in the number of students selecting science from Year 10 into Years 11 and 12 (DEST, 2006; Fullarton et al., 2003). Importantly, this phenomenon is not unique to Australia with many OECD countries facing similar difficulties in terms of student participation and engagement in the enabling sciences in the secondary years of schooling (i.e., physics, chemistry and mathematics) (Osborne & Collins, 2001; OECD Global Science Forum, 2006; Sj∅berg & Schreiner, 2005).

The impact of individual teachers on student engagement and achievement is well documented in the research literature (see Hattie, 2003 who considers a meta-analysis of some 500 studies). However, if cohorts of students are to be enthused and encouraged into the enabling sciences, faculties of teachers need to be able to work as a team in a cohesive and supportive manner. Recent studies in this area undertaken in New South Wales schools achieving high value-added outcomes for their students highlight a number of key features common to successful faculties (Ayres et al., 2004; Panizzon et al., 2007; Pegg et al., 2007). These include:

- Collaboration and commitment to the faculty group by individual teachers;
- High standards and expectations of students and teachers shared across the faculty and school;
- Interest, enthusiasm and passion for science and mathematics evident in the teachers;
- Quality pedagogy with a high degree of mentorship of young or inexperienced staff;
- Sharing of resources and collaborative assessment practices with all teachers involved in the process;
- Service by staff within the school for 8-10 years;
- Commitment to maximising learning outcomes for all students; and
- Support from senior executive in the schools.

Focusing on pedagogy particularly, one of the most significant areas of concern to emerge from research studies is that school science is perceived by many students to be irrelevant and ‘boring’ (Goodrum et al., 2001; Osborne & Collins, 2001; Tytler, 2007). A mechanism for addressing this perception of students is by moving towards a ‘contextual’ approach to the teaching of science and mathematics with a greater focus around the relevance of these subjects to society (Fensham, 2000; Rennie & Goodrum, 2007). Such an approach requires changes to the content of the curriculum and the pedagogical approaches used by teachers in the science classroom by developing links with industry, higher education institutions and expertise within the local community. Importantly, if science teachers are to embrace these changes they too need access to professional learning that supports, challenges and builds their subject discipline and pedagogical knowledge in an ongoing and dynamic manner (Loughran *in press;* Watson & Manning, 2008).

This paper presents the findings from a project set up to support teachers engage students in science through the establishment of links with scientists and engineers in their local community. While the aim of project was on student engagement, as demonstrated from the literature above, this is not possible without teacher engagement and commitment. Here we provide an overview of the context of the project, the process used in working with teachers in schools, and the research design underpinning the project. Findings focus primarily around the impact on science teachers although some student data is presented to demonstrate that change in their engagement with science was clearly evident.

SCHOOL TO WORK: SCIENCE INNOVATION PROGRAM

The main purpose of this program was to support teachers in making science more meaningful for students in Years 10, 11 and 12 in South Australia. To achieve this end, each participating school developed a project around a specific context (e.g., Defence or Mining) with a view to increasing levels of student engagement and awareness while enhancing aspirations to continue along science-related pathways. For example, in one school the focus for science was to increase student awareness of the alternative career pathways around engineering and science using a Defence context. Alternatively, in a school catering for a lower socio-economic clientele, science teachers set out to raise student self-efficacy and confidence as a means of enhancing student engagement in school science and mathematics.

To support projects each school was allocated approximately $14 000 for the year. While there was a degree of flexibility for teachers to design and implement a project appropriate to the needs of their particular students, an underlying premise was the establishment of links with scientific expertise in industry, universities and other institutions. Taking the example of the school using the Defence context above, one of the mechanisms used initially for getting students to engage with expertise in industry was to run a 'speed dating with engineers' event. Having briefly met and chatted to a number of experts, students selected a project for exploration working with this expert.

As such, this structure allowed science teachers to select a context relevant to their cohort of students and to negotiate the expertise necessary as required for the duration of the project given that funding was available. In addition to supporting the needs of students, a professional learning community for the science teachers was created across the schools facilitating the sharing of ideas, resources and scientific expertise.

Process for working with teachers

Each school in the project was expected to (i) involve a core group of science teachers (including coordinators); (ii) ensure regular meetings of the staff involved to facilitate communication and sharing of ideas; (iii) use a major proportion of the money for Temporary Relief Teachers (TRTs) so that teachers involved could allocate quality time to the project; (iv) allocate the remainder of the money to financially supporting the involvement of scientific expertise when required; and (v) demonstrate that the senior executive (e.g., principal and/ deputy principals) supported and endorsed the project.

The core document for each school was an Action Plan that detailed the particular strategies to be developed, the expertise and industry links to be established against a timeline, and budget. The project team critiqued these plans with suggestions made where appropriate.

Throughout the year each school was visited on a number of occasions by the project team with a Project Officer permanently available via phone and electronically. In this manner teachers were supported while being able to access the expertise they required as the need arose *within their teaching context*. To ensure that the projects in each school maintained focus, two sharing days were held with each team of teachers required to report back to the whole group about the progress to date. These days were held in July and December 2008.

RESEARCH METHODS

Fourteen secondary schools representing government, catholic and independent systems participated in the program. These schools were selected using a number of criteria by a panel including members of the project team and senior educational officials.

The research design was interventionist with baseline data collected using a number of sources prior to commencement and at the completion of each project. Initially, students in each school completed an online survey consisting of 95 Likert scale items taken from the attitudinal survey used for PISA 2006 (OECD, 2005). These covered a number of constructs including: experience of school science, enjoyment of science, self-efficacy in science, self-concept in science, general and personal value of science, views on science, sources of scientific information, interest in learning science, awareness of environmental issues, motivation to learn science, and teaching and learning science. The survey took 25-30 minutes to complete.

Interviews were undertaken with the principal and science team involved in the project in each school. These data provided a baseline to monitor any changes in student attitude and engagement along with impacts on science teachers.

With initial data collected, projects were implemented over a 7-month period. Upon completion, students undertook the same survey while interviews were again conducted with the science staff in each school. Finally, each school produced a case study report, which documented the processes used for project implementation along with the successes and associated issues that emerged. These reports were collected for documentary analysis.

Student survey data were analysed using descriptive statistics to enable comparisons with the Australian data available for PISA 2006. Once the pre and post-survey responses were analysed, the differences between the two sets were calculated as a means of determining any changes in the pattern of attitudes.

MAJOR FINDINGS AND DISCUSSION

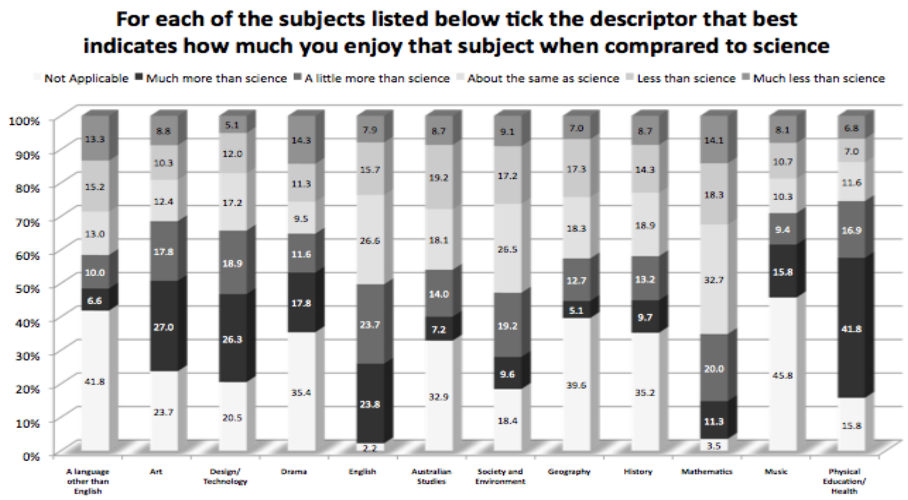
Overall, involvement in the projects led to greater cohesion among science teachers in each of the schools and an increased level of collaboration that was evident by a shift in teacher pedagogy. For students there was an increase in student engagement, particularly regarding their aspirations to continue on science-related pathways from school to work. This shift was evident from the attitudinal changes that emerged from the surveys.

Changes in student attitudes

In terms of student attitudinal changes between the pre and post-project responses, major shifts were noted across the majority of schools. While a number of constructs were explored in relation to the project, data for two constructs are presented here.

Experience of school science

As a group in the pre-survey responses (Fig. 1a) students expressed ambivalence towards science with no greater like or dislike of science when compared to other subjects. The only exceptions to this trend demonstrating greater student enjoyment were physical education, design and technology, art and English. However, over the course of the project, students' preferences shifted towards science and away from other subjects with greater proportions of students selecting the 'agree' and 'strongly agree' options for science in the post-survey responses (Fig. 1b). Figure 2 illustrates the change in student opinion regarding their enjoyment of science as a result of the intervention within each school.



b

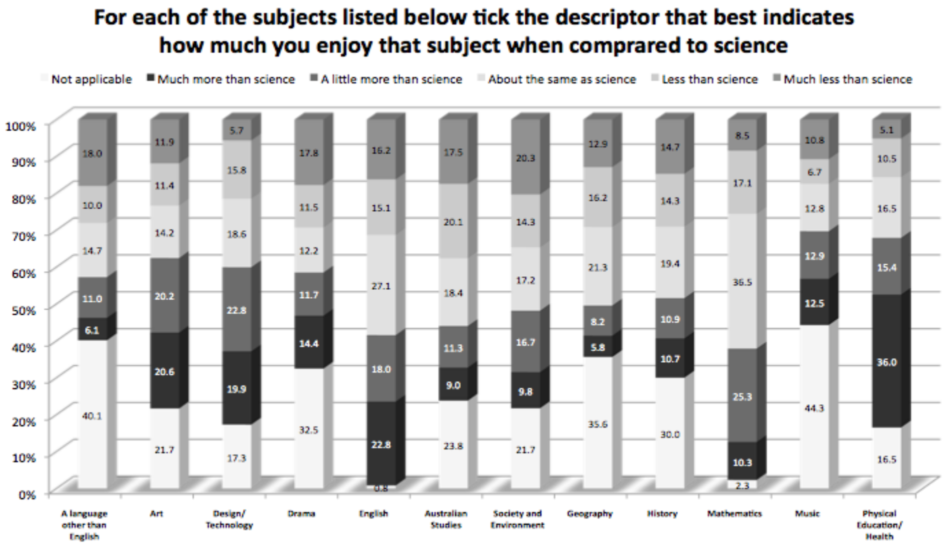


Figure 1. Pre (a) and post-survey (b) responses for students' enjoyment of science

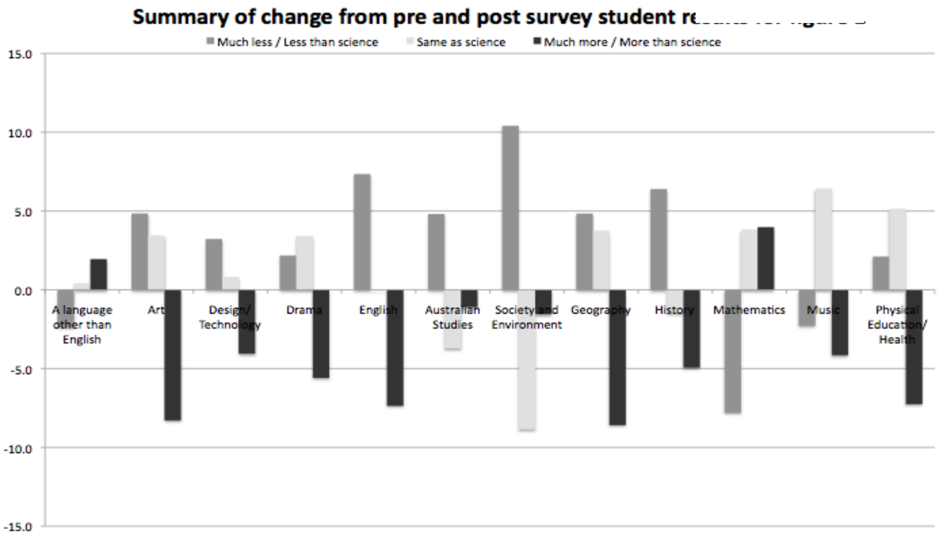

Figure 2. Student enjoyment of science: Differences between pre and post-survey results

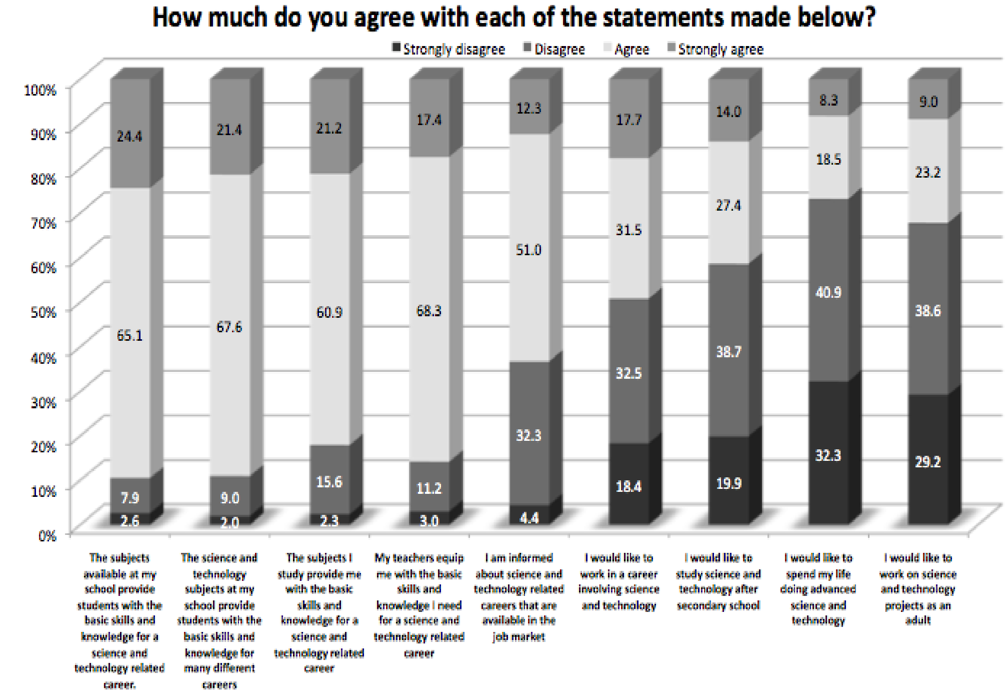
It is clear from these findings that students' preferences for science compared to other subjects increased with the notable exception being mathematics. Surprisingly, this subject experienced a notable increase in popularity compared to science. A possible explanation for this observation was that the science focus of many of the projects tended to highlight the closely linked role of mathematics, which may have provided students with a more meaningful contextual application for mathematics as a subject.

Motivation to learn science

At the beginning of the project (Fig. 3a, first four items), more than 80% of students generally 'agreed' or 'strongly agreed' that school was equipping them with the science-related skills they needed for their futures whether in science, technology, engineering, mathematics (STEM) or related careers. However, after the project (Fig. 3b, first four items) the greater proportion of students were questioning the degree to which their school science experiences were equipping them for their future. This is demonstrated clearly in Figure 4 by the negative results for the first four items, which indicate a decrease in the number of students selecting the 'agree' and 'strongly agree' options on the post-survey.

An interesting finding to emerge for these data is that despite overwhelmingly agreeing that the school was giving them the skills for participation in STEM-related careers, before the project, the proportion of students who aspired to pursue a career in the STEM-related areas was low (though slightly higher than the state and national averages for Australia for PISA 2006 (Thomson & De Bortoli, 2008) (Fig. 3a, last five items). However, after the project (Fig. 3b, last five items) there was a considerable increase in the proportion of students aspiring to follow pathways to STEM-related careers (see Fig. 4). So much so that the proportion of students who "would like to study science and technology after secondary school" and those who would like to "spend [their lives] doing advanced science and technology" rose to more than double the PISA national and state averages for Australia (Thomson & De Bortoli, 2008).

a



b

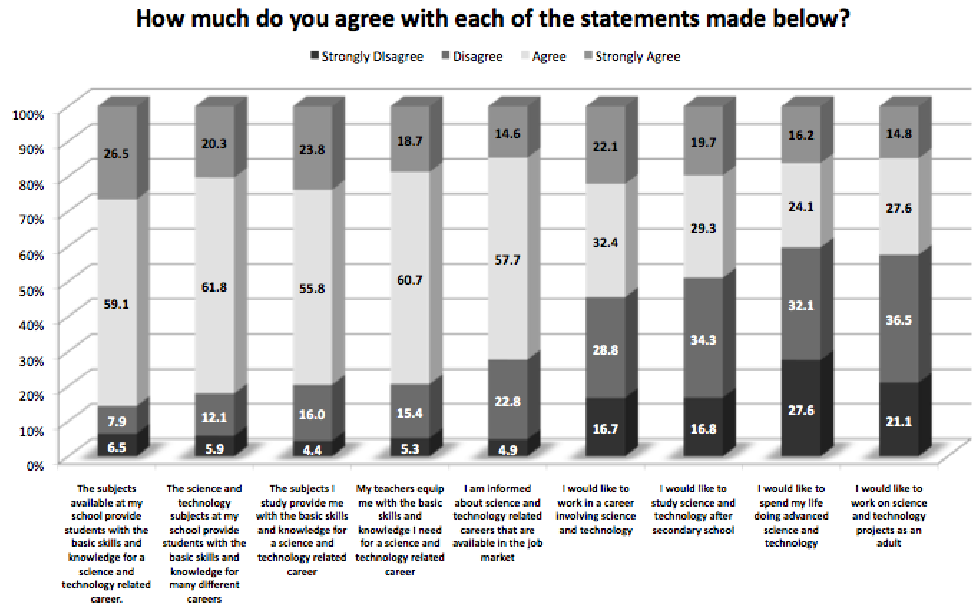


Figure 3. Pre (a) and post-survey (b) responses for students' motivation to learn science

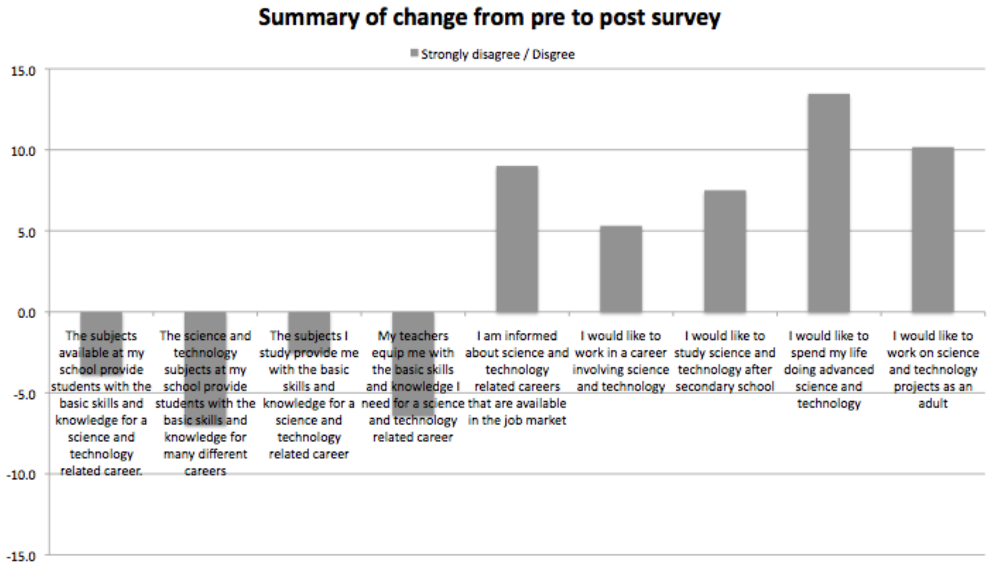

Figure 4. Student motivation to learn science: Differences between pre and post-survey results

In addition to these survey results, other aspects around student engagement noted by science teachers in their school case study reports included:

- increases in student satisfaction (often recognised by teachers outside of the science faculty);
- increases in student uptake of physics and chemistry at a senior secondary level (i.e., Years 11 and 12) in the majority of the schools;
- decreases in student behavioural problems; and
- increases in student attendance records in a number of schools.

Changes in science teachers

The central theme that emerged for teachers was a perceived improvement in the nature and quality of their relationships within the school. This occurred within the science faculty and with staff-student relationships.

> *It was really interesting that both the staff and students responded well to what was happening in science. As teachers we seemed to establish a stronger rapport and others noticed a change in the way in which they related to the students. We even had teachers from other faculties comment on how engaged the students seem to be with their science* (Science teacher).

It is this central and fundamental factor that has been demonstrated in previous research (see Panizzon et al., 2007) as it forms a cornerstone for the nature and quality of the learning experiences for students in science. Yet, establishing and maintaining these relationships are time consuming and require the opportunity for ongoing communication. In terms of staff-staff relationships, evidence emerged of consolidation 'as a team' with a high degree of collaboration and unification rather than a series of individuals working on a particular project. The allocation of time to physically meet, share ideas, work together, and discuss particular aspects provided informal professional learning within the school that helped establish a precedent for working collaboratively into the future.

> *Sustainability is possible because people have been able to collaborate and are prepared to work together … We've set a tone if you like of how to work together and that's going to be something that we will build upon and sustain by using our faculty meetings more effectively* (Science coordinator).

A number of the science teachers referred to the importance of having a single focus around the project as a means of helping create the necessary synergy. Being able to concentrate efforts and build upon the skills and expertise of the teachers involved in the projects collectively helped ensure greater impact for students, teachers in individual schools, and the broader school community.

In the majority of cases, it was increased levels of reflective practice that was critical in helping teachers monitor student engagement, involvement and achievement in relation to the scientific experiences. While a number of teachers spoke about their own personal reflections, it was the opportunity to extend this to the broader network that became particularly insightful.

> *It was the continuous discussions, continuous monitoring of students' achievements in relation to what we were doing that really helped me. I became more engaged, more involved as there were less communication barriers and a more friendly feel. Having access to a network of teachers in the same boat as me was so incredibly supportive* (Science teacher).

Overall there was increased engagement and enthusiasm from the teachers involved in the projects within their own schools. At least 90% of science teachers commented in their final interviews that they felt “re-energised and re-invigorated”. For one teacher there had been a significant reduction in stress levels because of the increased collaboration, access to external expertise, a network of science teachers, and the change in the attitudes of students in the classroom.

> *This project left the team more enthused and ideas for further units have already been floated. Our engagement in non-traditional ways of teaching has helped expand our pedagogy* (Science coordinator).

> *The staff is a lot happier because before we had a lot of behaviour issues but there are now quite a few less student behaviour management problems* (Science coordinator).

In relation to accessing expertise in industry, university and the community, teachers considered this to be critical in allowing them to upgrade their own scientific knowledge and their understanding of career options in the enabling sciences (chemistry, physics and mathematics). This highlights the value of thinking about these links at two different levels. The first might be directed towards teachers and the opportunity for them to engage with scientists and experts as a means of improving their personal understanding within the science discipline area. The second with a focus on student engagement with ‘real world science’ and the kinds of experiences that help broaden their awareness in terms of future careers options.

Pedagogy also became a target in the majority of schools as science teachers trialed new strategies to engage their students. For example, teachers commented on their move away from ‘chalk and talk’ and the use of textbooks to an increase in the diversity of activities they included in the science classrooms. As a result, engagement in the project and the opportunity to collaborate with peers in the same school and across schools helped to ‘raise the bar’ in terms of pedagogy.

> *I think it has been really positive because there’s been a greater variety of learning activities happening. Students have come into class and it is just not predictable. There is less chalk and talk here and the group work has become more productive. It has certainly raised the bar but we know there is still more to do* (Science teacher).

Discussions with scientists and engineers reiterated the importance of open investigations and the need for science teachers to move away from the traditional recipe-driven, predictable experiments that prevail in most school science classrooms (even though most curricula in Australia refer to inquiry and investigative approaches in science). Additionally, they recognised the need to embed the development of higher-order thinking skills in the science programs to meet the needs of all students but most especially their scientifically capable students. Again, without incorporating this focus into their units of work and science programs the extension of these students was likely to be overlooked from year-to-year. An important observation noted by the research team was that science teachers in general found it difficult to identify scientific activities and experiences likely to provide students with the opportunity of engaging with and developing these higher-order skills.

These latter points regarding access to expertise emerged as being critical for science teachers. Clearly, just as we recognise student diversity so too teachers are located along a continuum of professional learning. Accepting this perspective means that if teachers are to move further along this continuum they need to be able to access discipline expertise and pedagogical knowledge when relevant to their own teaching context. Considered in this way, professional learning is meaningful for teachers as the new ideas can be incorporated into the classroom instantaneously. The following quote exemplifies this point:

> After emailing …, Trudy came out and that was really fantastic for all of us. We were all there together and she showed us Wiki spaces and that was easy. This allowed me to go away and set up my groups with my students and it was all fantastic. Having access to that expertise when you need it is really important - rather than have the training and development and then you forget it before you apply it to the classroom (Science coordinator).

In other words, teachers too require *just in time learning*, which is not provided with traditional professional development approaches used by educational systems globally.

It is important at this point to recognise the difficulty of discerning what changes in teacher and student engagement related to the nature of the actual project undertaken in each school and the impact that simply being part of a research project had on science teachers and then subsequently their students (i.e., the Hawthorne Effect). From our perspective, it was not about micro-managing the individual school projects as we conceded that teachers probably had the best idea about their own situation but needed support in implementation. Rather our focus was around the networking and the quality of professional learning the teachers were able to access and it is often this aspect that is severely overlooked in traditional professional development programs. However, the project is continuing over the next two years with a number of the same schools involved over this period. This will allow longitudinal data to be collected that should provide more substantive evidence about the degree to which the results shared here relate to the projects and teacher engagement with professional learning compared to a Hawthorne Effect.

CONCLUSION

The *School to Work Science Program* provided extensive details about the successes experienced by teams of science teachers as they developed and implemented a range of different scientific opportunities for their student cohorts. Teaching via contexts and accessing scientific expertise available in the community clearly helped to make science meaningful to students. However, critical to the success of this program is that teachers were able to access this expertise, information and support when relevant to their teaching so as to enhance their own professional learning. It was this component that became the major focus of the program rather than the nature of the school-based projects.

ABSTRACT

The study investigated fourth- and sixth-grade students' cognitive abilities and problem-solving strategies. Eighty students were individually interviewed as they were experimenting with an improvised device. The device consisted of a wooden box with eighth electric lamps in a line and five switches, in another line, which could move up and down. Each interviewee was asked to "think aloud," prior and after any experiment with the device. The lamps and the switches were connected in a "hidden" circuit inside the box, in a way that only one or none of the lamps could light on. The interviewees kept a record of their observations. The results showed that students were inclined to mainly collect evidence from the experimental space. Students also failed to employ the control-of-variables strategy, but they were able to employ a not fully developed combinatorial reasoning. In addition, they had difficulties to effectively organise their results and did not take full advantage of their recorded data. They did not exhibit the ability to co-ordinate their hypotheses with the collected evidence. The results of the study can guide further research for identifying patterns of students' cognitive development and design teaching scenarios conducive to accelerating their cognitive growth.

Keywords: *Scientific reasoning, problem-solving, control of variables, combinatorial reasoning*

INTRODUCTION

The development of scientific reasoning has been the goal of many reform efforts in science education during the last decades. Scientific reasoning broadly defined includes many procedural and conceptual activities, such as, theory generation, experiment design, hypothesis testing, control of variables, data interpretation, coordination of theory and evidence, evaluation of evidence, use of apparatus, performing statistical calculations and many others (Keys, 1994; Zachos, Hick, Doane & Sargent, 2000). Due to this complexity, earlier studies had limited their scopes by giving attention either on the procedural or on the conceptual aspects of scientific reasoning. Klahr and Dunbar (1988, Klahr, 2000) developed an integrated model that incorporated domain-general strategies with domain-specific knowledge. This model conceived scientific reasoning as problem solving that is characterized as a guided search and information gathering task. The model is known as SDDS model (Scientific Discovery as Dual Search). According to this model scientific discovery is accomplished by a dual search process. The search takes place in two related problem spaces, namely, the hypothesis space and the experimental space. Searching the hypothesis space involves the process of generating new hypothesis based on some knowledge about the domain either as prior knowledge or as knowledge through experimentation. Searching the experimental space involves the performance of experiments that will yield interpretable results. Search in the two spaces is mediated by a third process, the evidence evaluation process. Evaluation assesses the fit between theory and evidence, and guides further research in both the hypothesis and the experimental spaces. Although original descriptions of SDDS model highlighted the "dual search," more recent descriptions acknowledge the coordination and integration of all three components (Klahr, 2000; Klahr & Li, 2005). The focus on the evaluation evidence phase has been influenced by the work of Kuhn (1989; Kuhn & Pearsall, 2000), who insisted that the heart of scientific thinking lies in the skills of differentiating and coordinating theory (or hypotheses) with evidence.

In the years since the appearance of the Klahr and Dunbar's model of scientific reasoning (1988), there has been a move toward research in which participants take part in all three phases of scientific activity (Kaselman, 2003; Schauble, 1996;). These approaches are called self-directed experimentation research (Zimmerman, 2000; 2007). In self-directed experimentation studies, individuals learn about a multivariable causal system through activities initiated and controlled by the participants. There are some features that are common to a subset of these studies. The first refers to the time that participants have been involved with the research. In some cases participants got involved with the investigation for one experimental session, while others involved repeated exposure to the investigation environment (Kuhn, 1995; Schauble, 1996). This repeated exposure is known as microgenetic method of study (Siegler & Chen, 1998). Another common feature was the use of a type of external memory system. Participants were provided with a data notebook or records card to keep track of plans and results or access to a computer file of previous trials (Trafton & Trickett, 2001; Gleason and Schauble, 2000). Given the importance of metacognition on such tasks (Kuhn and Pearsall, 2000), it is important to determine at what point students and adolescents recognise their own memory limitations as they navigate through a complex task.

The results of these studies showed common developmental differences between students and adults. Students' performance was characterised by a number of tendencies, such as, to generate uninformative experiments, to make judgments based on inconclusive or insufficient evidence, to focus on causal factors and ignore non causal factors, to have difficulties disconfirming prior beliefs, and to be unsystematic in recording data. The results also revealed differences in experimentation strategies and divided participants as engineers or scientists according to the goal of their experimentation (Schauble, Raghavan, & Glaser, 1991; Schauble, 1996). Thus, students working as scientists attempt to determine which factors make the differences and which do not, and they work more systematically and try to establish the effect of each variable and make an effort to include inclusion and exclusion inferences. On the contrary, students working as engineers attempt just to achieve a desired result, they select highly contrastive combinations, and they concentrate on factors believed to be causal while overlooking factors believed or seemed to be non-causal.

The present study was based on the Klahr and Dunbar model (1988, 2000) and on previous research (Papageorgiou & Valanides, 2002; 2003; 2006; Valanides & Papageorgiou, 2001) and took into account self-directed experimentation research. The study attempted to investigate fourth- and sixth-grade students' problem-solving strategies and related cognitive abilities. More specifically, this research investigated students' ability to form and test hypotheses, to control variables, to coordinate theory and evidence and to apply combinatorial reasoning.

METHODOLOGY

Initially, ten elementary schools were randomly selected from a geographical district of Cyprus and, from each school, a fourth-grade and a sixth-grade class were also randomly selected. The total number of 498 students (250 sixth graders and 248 fourth graders) was administered a six-item questionnaire consisting of three problems relating to control of variables and three other problems relating to combinatorial reasoning. Students performance on the questionnaire had a range of scores from 0-18, since for each answer to a problem a score 0 (totally incorrect answer) to 3 (totally correct) was assigned. Based on students' performance on the questionnaire, two different groups of students were separated. The first group included students who had a score between 4 and 7 (the low achieving students), and the second group included those students who had a score from 14-17 (the high achieving students). These cut-off scores were decided based on the total distribution of students' scores on the questionnaire. Thus, four strata of students were formed, namely, high achieving students (fourth and sixth graders), and low achieving students (fourth and sixth graders). Finally, 20 students from each stratum were randomly selected.

Individual interviews were conducted with these 80 students as they were investigating an improvised device. The device consisted of a wooden box with eight small electric lamps in a line and five switches, in another line below the lamps, which could move up and down. The lamps and the switches were connected in a "hidden" circuit inside the box, in a way that only one or none of the lamps could light on, while a "tester," or a general switch, located below the five switches, was used to test whether one or more lamps were lit on. The lamps and the switches were connected in such a way, so that only one lamp could light on with different combinations of the switches. Switch number 3 constituted the general switch of the device and switch number 5 was not connected to the electric circuit of the device at all.

When students came to the interview sessions, they were presented with a simpler device consisting of one lamp and a similar "tester." The interviewer, in a game-like fashion, explained the function of this device and the role of the switch and the tester. Then, the main device was presented and students were asked to form "initial hypotheses" about its functioning. Subsequently, they were asked to carry out experiments and test their hypotheses. The students were instructed to "think aloud," prior and after any experiment using the device. The interviewees were instructed to proceed in a step-by-step fashion and keep a record of their observations. The record of their observations was used as a type of external memory system. Each interview was tape-recorded, and transcribed for data analysis.

The data were analyzed qualitatively and quantitatively. For the quantitative analysis each interview was carefully analyzed using the constant comparative analysis approach. With this analysis each dependent variable was analyzed in different qualitatively different levels indicating a progression in performance. The lowest level of performance was assigned a score of 0 and each progressively better level of performance was assigned progressively a score of 1, 2 etc. Thus students' performance on each dependent variable was quantified, while the sum of the six dependent variables (identifying the general switch, identifying the dummy switch, lighting the lamps, combinatorial reasoning, ability to control of variables, ability to co-ordinate theory and evidence) that were considered constituted the Investigation Ability of each student.

RESULTS

Qualitative Analysis

When students came to the interview sessions they proposed their hypotheses prior to experimenting with the device ("initial hypotheses.") Table 1 presents a sample of students' initial hypotheses.

Table 3. Students' Initial Hypotheses (H_n)

Hypothesis (H_n)
H_1: Different lamps will light up when different switches are used in combination, and all lamps can light up.
H_2: Lamps will light up, one at a time, using a different switch. Only five lamps can light on.
H_3: One or more lamps can light up when only one switch is used. Multiple lamps can be simultaneously lit up.

Students proposed a variety of initial hypotheses, mainly based on their prior knowledge and observations. Only four students were able to form at least a hypothesis using their combinatorial reasoning and considering the device as system of integrated parts (H1). After a series of experiments, almost all the students modified their initial hypotheses. Nine fourth graders and 17 sixth graders identified the general switch, but only 5 of them gave it the right name. Among them, 14 students applied co-ordination of their hypotheses and collected evidence to solve the problem of the general switch and the other 12 students examined only the collected evidence and their records to solve the problem.

On the other hand, more students (18 fourth graders and 23 sixth graders) identified the "dummy" switch and 15 gave it the right name. The rest of them proposed, for example, that the "dummy" switch was more important, because "it could make the lamps light up twice." Interestingly, all the students, who solved the problem of the dummy switch, searched only the experimental space and did not search the hypothesis space. Additionally, all students managed to discover which combinations of switches could light up every lamp.

Besides, the students did not exhibit the ability to co-ordinate their hypotheses with the collected evidence. They considered that only "positive" experiments, that is, experiments where a lamp could light up, were useful for their investigation. Only 26 out of 80 students formed a hypothesis with the possibility of a negative experiment. Most of the students were inclined to mainly search the experimental space rather than the hypothesis space. Only 5 students took into consideration contradictory data and modified accordingly their hypothesis. The majority of students (68 out of the 80 students) exhibited confirmation bias, that is, they tended to test their proposed hypotheses using only experiments that could confirm their stated hypotheses, but did not use any experiments that could disconfirm them.

Students' combinatorial reasoning was examined based on the number of identical experiments and the number of the redundant experiments they performed, and their ability to move the switches up and down systematically. Obviously, some students were unable to discern patterns in their recorded observations and repeated some identical experiments (same combinations of switches). Only 13 students did not perform any identical experiment, and 21 students performed more than 3 identical experiments. The remaining 46 students performed from 1 to 3 identical experiments. They also performed redundant experiments, because of their inability to control variables or their limited combinatorial reasoning. Only 25 students were able to employ a more developed combinatorial reasoning, moving the switches up and down in a systematic way. For example, the student 6L214 (6 refers to the class, L refers to Low Achieving based on performance on the initial six-item questionnaire, and 214 is the number of the student in the initial sample of the study) performed the following experiments: 11000, 10100, 10010, 10001, 01100, 01010, 01001,00110, 00101, 00011. The five numbers represent the five switches of the device. Number 0 refers to up position and number 1 refers to down position. It is obvious, from this sequence of experiments, that the child used a developed combinatorial reasoning, because he tried to performed experiments where only two switches were at the down position and he managed to perform all the possible experiments where all the relevant combinations were used.

Students' ability to control variables was also examined. A student was considered that employed the control-of-variables strategy when in two successive experiments moved only one switch. Almost all students faced difficulties in controlling the variables, since only one student managed to apply this strategy in more than 75% of his experiments and almost all the students (68 out of 80) controlled variables in less than 50% of the performed experiments.

Based on the results, five distinct experimentation strategies were used during the investigation with the main experimental device. The five strategies are presented starting from the most simple and undeveloped strategy to the most complex and most developed strategy.

- *Strategy 1 Random search of the experimental space only.* Students who followed this strategy used a trial and error strategy by performing random experiments that did not follow from any previous hypothesis. These students were not able to solve any part of the problem.
- *Strategy 2: Systematic search of the experimental space only.* Students who used the strategy 2 performed experiments that did not refer to a specific hypothesis. On the other hand, they performed experiments while they were using systematically different combinations of switches
- *Strategy 3: Random search of the hypothesis space without the ability to solve the problem.* Students who applied strategy exhibited the ability to formulate several hypotheses by searching the hypotheses space, but were not able to verify their hypotheses based on their experimental results. Consequently, they were unable to co-ordinate hypotheses and experiments in order to solve the problem.
- *Strategy 4: Ability to solve the problem based on the experimental space and not on the co-ordination of evidence and theory.* The students who applied this strategy were able to identify general or/and dummy switch, but they did that based only on the experimental results and without coordinating evidence and hypotheses. So, they managed to solve the problem when they were prompted to carefully examine their recorded data.
- *Strategy 5: Searching the hypothesis and the experimental space. Co-ordinating theory with evidence.* Students who applied this strategy were able to solve the problem by co-ordinating their hypotheses with the experimental results. They formulated hypotheses and they modified them based on contradictory data.

Table 2 presents the number of students who followed each strategy, based on their initial abilities and their age.

Table 2. Investigation Strategies

Strategies	Frequencies				Total
	4th Grade		6th Grade		
	Low Abilities	High Abilities	Low Abilities	High Abilities	
1	8	0	5	0	13
2	3	3	10	0	16
3	7	2	3	2	14
4	2	10	2	9	23
5	0	5	0	9	14

Quantitative Analysis

Using the constant comparative analysis method, separate rubrics for evaluating the six different variables that were considered as components of students' investigation ability had been developed. The levels of each rubric were not predetermined, but emerged inductively from the analysis of the interviews. Each progressively higher level in any rubric differed from the preceding level, because it contained elements of improved effort or answer. The lowest level of each rubric indicated that students did not develop the ability that was represented by the specific variable, or that they had the lowest possible performance on that variable, and a score of 0 was assigned to this level of the rubric. Students' performance on any higher level was progressively assigned a score of 1, 2, 3 etc, respectively, since each higher level indicated a qualitatively better performance. Thus, each of the six variables was quantified by assigning progressively increasing scores for each higher level of the six different scoring rubrics relating to each of the six variables

Table 3 presents the results of the multivariance analysis MANOVA 2 (Abilities) X 2 (Grade) with depended variables the six variables that were considered as components of students' Investigation Ability.

Table 3

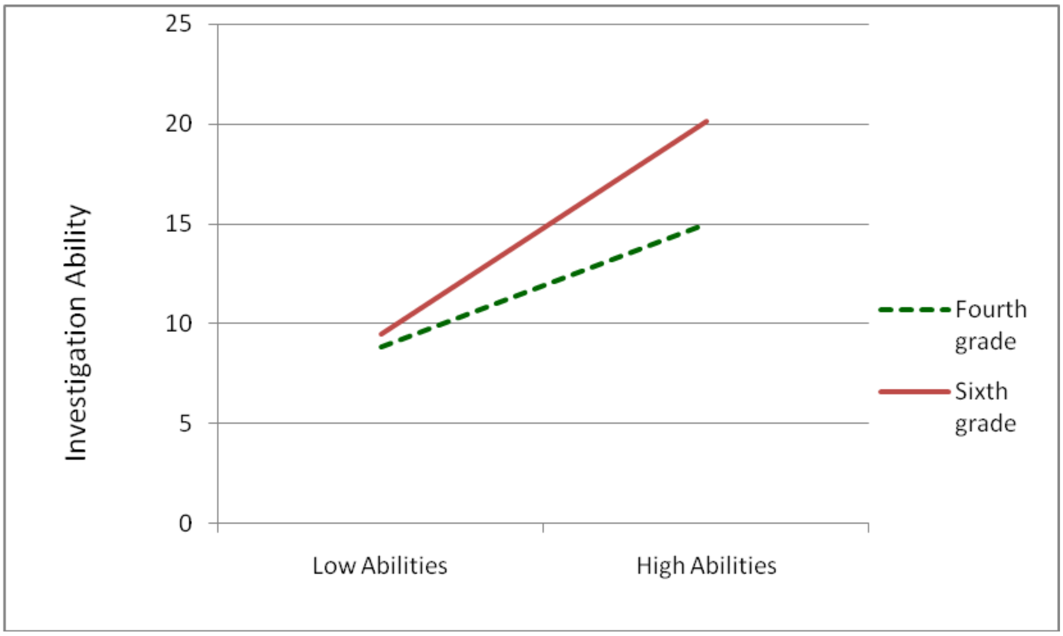
In depended variable	Depended Variable	F	P value
ABILITIES	General Switch	9.609	0.003*
	Dummy Switch	1.898	0.172
	Lighting of Lamps	0.409	0.525
	Control of Variables	0.336	0.564
	Combinatorial Reasoning	0.727	0.396
	Co-ordinate th. And evid.	9.828	0.002*
	Investigation Ability	9.096	0.003*
GRADE	General Switch	46.051	0.001*
	Dummy Switch	56.803	0.001*
	Lighting of Lamps	1.634	0.205
	Control of Variables	0.084	0.773
	Combinatorial Reasoning	39.111	0.001*
	Co-ordinate th. And evid.	33.433	0.001*
	Investigation Ability	79.018	0.001*
ABILITIES X GRADE	General Switch	0.795	0.011*
	Dummy Switch	0.001	0.376
	Lighting of Lamps	0.001	1.000
	Control of Variables	0.020	1.000
	Combinatorial Reasoning	11.652	0.887
	Co-ordinate th. and evid.	5.669	0.001*
	Investigation Ability	0.795	0.020*

Note: * shows the statistically important results.

The results of MANOVA Analysis showed that there were statistically significant differences between high and low ability students for the variables "General Switch" [F (1, 80)= 46.051, $p.$=0.001], "Dummy switch" [F (1, 80)=56.803, $p.$=0.001], "Combinatorial reasoning" [F (1, 80)=39.111, $p.$=0.001], "Co-ordinate theory and evidence" [F (1, 80)=33.433, $p.$=0.001] and "Investigation Ability" [F (1, 80)=79.018, $p.$=0.001], where high ability students performed better than low ability students. Statistically significant differences between fourth and sixth graders were also identified for the variables "General switch" [F (1,80)=9.609. p=0.003], "Co-ordinate theory and evidence" [F (1, 80) =9.828. $p.$=0.002] and "Investigation Ability" [F (1, 80) =9.096. $p.$=0.003], where sixth graders performed better than fourth graders.

Table 3 also shows that the interaction effect between abilities and grade was statistically significant for the variables “General switch,” “Co-ordinate theory and evidence” and “Investigation Ability,” where sixth graders with high abilities performed better than fourth graders with high abilities (General switch: t=-3,49 and $p.$=0.001, Co-ordinate theory and evidence t=-4.43 and $p.$=0.001 and Investigation ability t=-4.013 and $p.$=0.001). On the other hand, the differences between sixth graders with low abilities and fourth graders with low abilities were not statistically significant. The nature of the interaction effect between abilities and grades in terms of students’ Investigation Ability is clearly understood from Figure 1. As indicated in Figure 1, the difference between fourth- and sixth-grade students’ Investigation Ability becomes larger for high ability, although this difference is less for low ability students.

Figure 1. The Interaction Effect between Students’ Grade Level and Their Abilities in Terms of their Investigation Ability



CONCLUSIONS AND IMPLICATIONS

The results of the study showed that among the students who were characterized as high ability students based on their performance on the initial six-item questionnaire there were more sixth-grade students than fourth-grade students, who had successfully identified the general and the “dummy” switch, while only few low ability students from both grades were able to do so. Even the students who had successfully identified the functioning of the main device, they could not be considered as “good solvers,” because they performed identical experiments, did not effectively apply the “control-of-variables” ability, and did not take full advantage of their external memory system (recorded data). The students in general did not exhibit advanced ability to coordinate their hypotheses (theory) with evidence, they were usually performing random experiments in the experimental space, and only few of them conducted experiments for testing previously stated hypotheses.

More specifically, the majority of the students failed to employ the control-of-variables strategy, but they were, to a certain extent, able to employ an immature and not fully developed combinatorial reasoning. When a student has well developed his/her combinational reasoning, then he/she will be able to combine the switches and to determine the total number of different experiments that can be performed with the specific device, or they will be able to exactly define the experimental space. Similarly, after identifying the general switch or the “dummy” switch, they will be also able to correctly conceptualize that the experimental space is accordingly reduced. In such a case, students will avoid conducting unnecessary experiments.

The statistical analysis of the quantified data indicated that the students who participated in the present study did not adequately develop their Investigation Ability (IA). IA was a compound variable consisting of several component variables. The component variables “Co-ordination of theory and evidence” and “Control of Variables” were less developed, while students appeared to have developed to a certain their combinatorial reasoning. Moreover, there were significant differences between high and low achievers, as they were characterized based on their performance on the initial six-item questionnaire. There were also significant differences between fourth- and sixth-grade students, although they were matched in terms of their performance on the initial questionnaire. These differences clearly indicate that other factors beyond the abilities of controlling variables and combinatorial reasoning contribute to students’ investigation ability. The significant interaction effect between grade and abilities in terms of students’ investigation ability indicates that the existing gap between high and low achievers becomes bigger as students become older. This effect seems to indicate that the existing educational system is tailored only to the needs of students that are at a higher stage of cognitive development, and does not address the needs of the diverse student population.

The study clearly suggests that the existing curricula and the dominant teaching practices are far from achieving the declared objectives of science teaching at the primary school. Similar research designs can be very useful in identifying patterns of students’ cognitive development and design of teaching scenarios conducive to accelerating their cognitive growth. Future research should focus on inquiry-based activities that seem promising in our attempts to improve teaching and learning in the primary school classrooms and beyond.

DEVELOPMENT AND APPLICATION OF LEARNING MATERIALS FOR SCIENTIFIC CREATIVITY AND ANALYSIS OF STUDENTS' RESPONSES ABOUT IT[18]

Jongwon Park

Chonnam National University, Gwangju, 500-757, Korea

jwpark94@chonnam.ac.kr

ABSTRACT

Nowadays, secondary school curriculum and educators have emphasized the creativity in school learning. Especially, there are growing evidences suggesting that creativity is domain specific. Few years ago, I developed a model of scientific creativity consisting of three axes; creative thinking, scientific knowledge, and scientific inquiry skills. Now, using this model, concrete learning materials for scientific creativity have been developed and applied to students in the 'center for the gifted in science' established in my university. As a result, it was observed that many students responded positively about the developed learning materials, especially, they answered that it was helpful for their creative thinking, and therefore, they wanted to lean this kind of materials in the future activity. In these learning materials, specific guides were included to encourage students' creativity activities. From the analysis of students' activities, it was also found that these guides could improve their divergent thinking which was a kind of creative thinking.

Keywords: *scientific creativity, teaching model, teaching strategy, students' responses*

INTRODUCTION

Creativity is domain-specific. That is, creativity in science may have different aspects compared to creativity in art or in literature. Gardner's theory of multiple intelligences (1983) also implicates that a creative scientist requires high level of logical-mathematical and naturalist intelligence while a creative politician requires strong linguistic and interpersonal intelligences (Solomon et al., 1999). This article starts from the model of scientific creativity (MSC) with the following three premises (Park, 2004):

(1) MSC should cover various thinking skills needed to perform or carry out scientific activities, such as divergent thinking, convergent thinking, and associational thinking.
(2) Creativity is content-dependent, so MSC should include scientific knowledge contents.
(3) Scientific creativity deserves to be manifested in the process of scientific inquiry, so MSC should reflect the model of scientific inquiry, and include scientific inquiry skills.

According to MSC, if someone invents a new experimental technique while designing an experiment (scientific inquiry skill) related to Faraday's law (scientific knowledge content) by thinking divergently (creative thinking), it is said that his/her new experimental technique is invented by virtue of scientific creativity. Or, if someone finds novel regularities by convergent thinking (thinking) in the process of analyzing experimental data (scientific inquiry skill)

[18] This is written based on Park(2004)'s article titled "A suggestion of cognitive model of scientific creativity" published in Journal of Korean Association of Science Education, 24(2), 375-86.

related to Ohm's law (scientific knowledge contents), his/her finding of new regularities can be viewed as being the product of scientific creativity.

From now on, I will describe the main characteristics of three creative thinking (divergent, convergent, and associational thinking), and discuss how creative thinking should be linked with scientific knowledge and scientific inquiry.

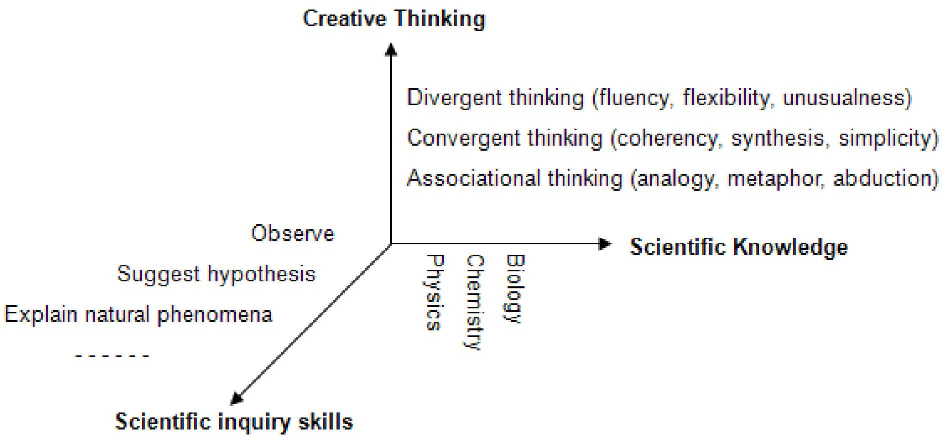

Figure 1. The model of Scientific Creativity (MSC)

DESCRIPTION OF THE MODEL OF SCIENTIFIC CREATIVITY

Divergent Thinking

Divergent thinking can be characterized by fluency and flexibility which are well defined as the ability to produce numerous and diverse ideas (Guilford, 1968; Runco, 1991). For example, if we ask someone to suggest ideas about the alternative use of a compact disc instead of listening music, the number of ideas generated corresponds to fluency and the number of categories of ideas corresponds to flexibility.

Here, I assumed that unusualness can be the third feature of divergent thinking. Unusual thinking is defined as seeing, thinking, and acting differently from previous and traditional views, ideas, and custom. The reason unusual thinking is involved as the third feature of divergent thinking is because there have been many instances in the history of science in which unusual thinking leaded to a paradigm shift in science or a new scientific discovery.

For example, when Kepler changed conventional belief that the orbits of planets were circular into the idea of elliptical orbits, when Dirac named the particle with negative energy being neglected by most scientists at that time an "antiparticle", when Einstein rejected the presence of "ether" which was assumed by almost all scientists as a medium of electromagnetic wave, the common characteristic of their thoughts was unusualness.

Therefore, Root-Bernstein (1999) notes that creative scientists enjoy playing mental games, such as 'what if', by doubting basic premises or by changing conventional definition. For instance, questions such as, "If the energy is not conserved?", "If we redefine the electric current as 'i=dq/dt' to 'i=dt/dq' ?", or "If the speed of light is decreased to 10km/s?" may be used to encourage unusual thinking among students.

Convergent Thinking

> "Now it is clear that creative work often requires critical and convergent thinking as well as divergent thinking." (Runco, 1999, pp. 449-450).

While divergent thinking corresponds to widening and spreading out thoughts, convergent thinking corresponds to collecting and structuring various thoughts. Here, I characterize convergent thinking as having following three features: coherence, synthesis, and simplicity.

Recognition of the presence of incoherence can play a significant heuristic role because it may lead to the discovery of new ideas and revision of previous models by virtue of an effort to eliminate incoherence (Nersessian, 2002). Thagard (1997) also insists that when coherence fails, the potentially more cognitive processes are triggered and, as a result, this incoherence can lead to new discovery. For instance, Einstein's special relativity was initiated from the following thought experiment conducted at 16 years of age: what would be the consequences of running alongside a light wave? If a light wave is seen as being static (according to Galileo' relativity theory), then is it also a wave? (electric and magnetic field of a light wave should vary with time according to Maxwell's theory). Park and Jang (2005) also observed that one of major three motives of physicists' research was recognition of conflict (Table 1).

Table 1. Research motives of actual physicists

M1: Incompleteness	
	M11: Inaccuracy of experiments
	M12: Unidentified/undeveloped areas
	M13: Unproven parts of the theory
M2: Discovery and Development	
	M21: Discovery of new data/phenomena
	M22: Suggestion of a new theory
	M23: Development of new materials
	M24: Development of new experimental techniques/equipment
M3: Conflict	
	M31: Mismatches between theory and experiment (unexplained phenomena)
	M32: Internal conflicts inside the theory

The level of synthesis depends on the number of concepts or ideas in constructing a structured system. In the history of science, we can see that scientific knowledge have developed with increasing the level of synthesis. For instance, electricity and magnetism were not connected with each other at first, however, after Ampere discovered a magnetic field around an electric wire flowing electric current, the two were interlinked. And by combining Ampere's law, Faraday's law, and Gauss's law into Maxwell's electromagnetic theory, electricity and magnetism were completely unified. Based on the fact that the speed of electromagnetic wave derived from Maxwell's theory was the same as the speed of light, electromagnetic wave was regarded as being the same as light. And by Einstein's photoelectric effect, wave was combined with particle.

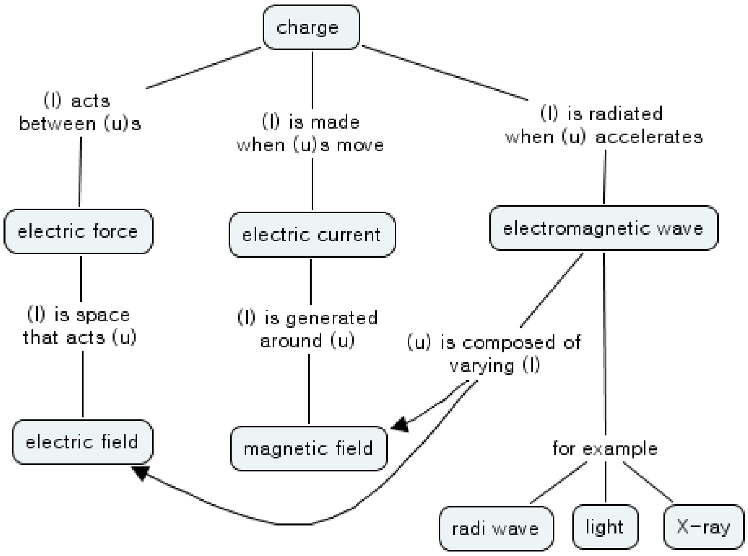

Figure 2. Concept map about electricity and magnetism.
Here, (u) means upper concept, and (l) means lower concept

To encourage synthetic thinking for students, Concept Maps™ (Novak & Gowin, 1984) emphasizing the meaningful relationship between concepts by connecting them using linking words can be useful (see Figure 2).

Although many ideas or concepts are collected together, the total structure needs to be simple. Therefore, many scientists have mentioned simplicity as a category for a good theory or solution as follows:

> "… he (Einstein) got the idea of connecting gravitation with the curvature of space. He was able to develop a mathematical scheme incorporating this idea. … The result of such a procedure is a theory of great simplicity and elegance in its basic ideas." (Dirac, 1979, p.92)

Associational Thinking

New ideas cannot be derived from nothing. They are invented by connecting it with extant ideas or borrowing other well-known ideas to understand new phenomena. Associational thinking plays an important role in discovering new ideas from other ideas. There are two types of associational thinking: Similarity-based thinking and Non-similarity-based thinking.

Analogy, metaphor, and abduction are involved in similarity-based thinking (Park, 2006). Mumford and Porter (1999) stress that analogical reasoning is one of the key components of creative thought, and define it as a map of similarity between two or more phenomena. Holyoak and Thagard (1999) note that among the four distinguishable uses of scientific analogy - discovery, development, evaluation, and exposition - the most exciting use of it is when a new hypothesis is discovered. They suggest several typical examples of analogy, such as Darwin's animal and plant competition-human population growth, Maxwell's electromagnetic force-continuum mechanics, and Kekule's benzene-snake dream. While they studied the role of analogy on theory construction based on the historical cases, Dunbar (1997) observed the real work of scientists in molecular biology laboratories for a long period, and found that creative scientists used various analogies very frequently and creatively when formulating a new hypothesis.

Metaphors have also been emphasized as a fundamental tool in creative thinking. For instance, Miller (1996) describes how metaphors are used as a means to invent new knowledge in terms of established knowledge for great scientists such as Einstein, Fermi, Heisenberg, Maxwell, Salam, Weinberg, and Yukagwa

Peirce (1955) argues that even though the process of creating a new hypothesis involves a psychological factor, it can also be viewed as a rational process. He says, "All the ideas of science come to it by the way of abduction. Abduction consists in studying facts and devising a theory to explain them" (Peirce, 1998, p. 205). Hanson (1961) also insists that guessing new idea comes not from induction or deduction, but from abduction which "involves sensing ways in which the current situation is somehow similar (analogous) to other known situations and using this similarity as a source of hypotheses in the present situation" (quoted in Lawson, 1995, p.7).

Park (2006) observed, based on the analysis of students' processes of explaining new phenomena which conflicted with their prior prediction, that students used similarity-based reasoning between the new phenomena to be explained and background knowledge which they already knew. Figure 3 indicates steps of generating new ideas using similarity-based reasoning.

> New Phenomena (NP) has properties α, β, and γ.
> Background Knowledge (BK) also has similar properties α', β', and γ'.
> Then, the NP and BK share similar properties with each other.
> And the BK has another property δ'.
> Therefore, it is worth inferring that NP will also have property δ,
> even though δ has not yet been confirmed.

Figure 3. The model of similarity-based reasoning

To encourage similarity-based reasoning with physics contents, the following questions can be useful: "Find similar properties between Faraday's Law and Hooks' Law as many as possible." The, for this question, students can answer that (1) both try to go back to their original state, or (2) two laws are about electromagnetic phenomena because restoring force in Hook's law is generated by electric attraction between molecules.

Not types of all associational thinking are based on similarity. Connecting or combining two ideas, even though they are not shown as sharing any similar properties with each other, can also lead to new ideas or novel products. For example, combining a wine glass with a liquid crystal thermometer can make a new wine glass indicating the proper temperature at which to drink wine, and "radio glasses" can be made by inserting a mini radio into a pair of ordinary eyeglasses with earphones connected to the glasses. In fact this, type of thinking is useful strategy for invention of new items in commercial situation.

Others: originality, value, and elaboration

If someone invents new powerful weapons, his/her activity cannot be regarded as a scientific creativity activity because it is not valuable for mankind.

> "… we shall define creative scientists as those whose work is considered high in both originality and value by other scientists in the same field." (Mansfield & Busse, 1981, p.3)

Elaboration is also another condition for good scientific creativity activities. Many scientific ideas were not discovered as a completed form but evolved and developed through successive articulation and refinement from the initial format of an idea. For instance, the initial atom model suggested by Bohr in 1913 had various shortcomings that could not be solved at that time. But the initial model was articulated and refined by regarding the nucleus as being composed of proton and neutron, by assuming that the nucleus moved around the center of mass, by modifying the circular orbit of the electrons into elliptical orbit in 1915, and by considering the relativistic effect of mass of the moving electron. The reason why electrons did not radiate electromagnetic wave during movement in the specific orbits around the nucleus could be solved later when De Broige's concept of "matter wave" was invented in 1925.

Role of scientific knowledge and scientific inquiry in Scientific Creativity

> "However, thinking alone will not lead to creative excellence, since creativity does not occur in a vacuum but in a particular field." (Cropley & Urban, 2000, p. 485-498).

Scientific creativity can be actualized by linking the previously mentioned three types of thinking with concrete scientific knowledge contents. In fact, Weisberg (1986) stated that creative persons had more professional knowledge compared to less-creative persons, and Wolpert (1992) pointed out that scientific intuition leading to new discovery related not to common-sense experience but to the highly specified knowledge (Wolpert, 1992, p. 64). These notes relate to Hempel's explanation about generating new scientific hypotheses. "Scientific (new) hypotheses are not *derived* from observed facts, but *invented* in order to account for them. … The inventive effort required in scientific research will benefit from a through familiarity with current knowledge in the field." (Hempel, 1965, p.15)

However, it is worth noting that background knowledge may obstruct the generation of new ideas. That is, background knowledge can narrow thinking and restrict it to the conventional (Cropley, 1999). This is also similar to the influence of existing well-established paradigm on the evaluation of empirical data or views conflicting with it. Kuhn (1977) found that scientists often fail to reject existing paradigms when faced with anomalies or counter-instances. This is because background knowledge usually has a lot of supporting evidences and so it is not easy to be doubted. Therefore, even though background knowledge is important to create new ideas, every inventor needs to go back to the state of novice minds.

> "In the absence of appropriate personal properties such as 'openness to the spark of inspiration,' flexibility, or courage to try the new, great expertise can inhibit the production of novelty. In order to achieve effective surprise, experts need to be capable of seeing the contents of their field in a fresh light. Creative experts often show a freshness and openness that is more typical of beginners; this has been referred to as the 'novice effect.'" (Cropley, 1999, p. 516)

In order to understand when creative thinking is necessary in the process of the scientific inquiry, we need to know the detailed processes of actual scientists' research procedure. Figure 4 indicates the actual physicists' scientific inquiry processes from from motives of research to the results of it (Park, Jang, and Kim, 2009).

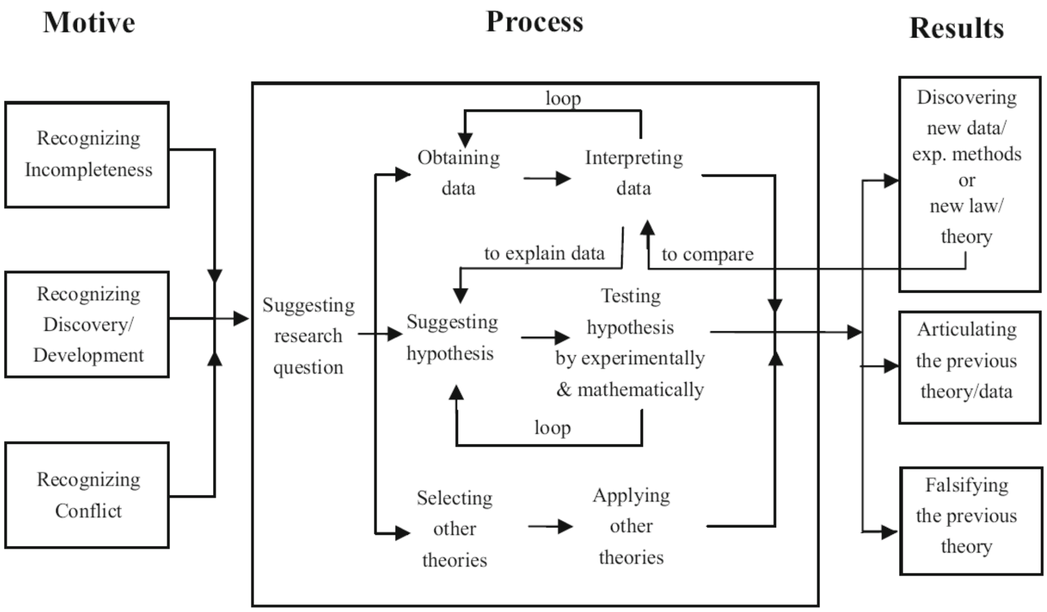

Figure 4. Scientific Inquiry Process

Here, important point is that scientific creativity should be actualized at a certain point of the process of scientific inquiry. For instance, when *obtaining and interpreting data,* scientific creativity can lead to the discovery of new features or hidden novel regularities. Or when *designing experiments to test scientific hypotheses*, scientist may invent new method required to obtain important data through scientific creativity.

STEPS FOR LEARNING SCIENTIFIC CREATIVITY

To teach scientific creativity, Park, Park, & Lee (unbublished) suggested learning model consisting of three steps: Activity spontaneously, Guides for creative thinking, Activity Again (see Figure 5).

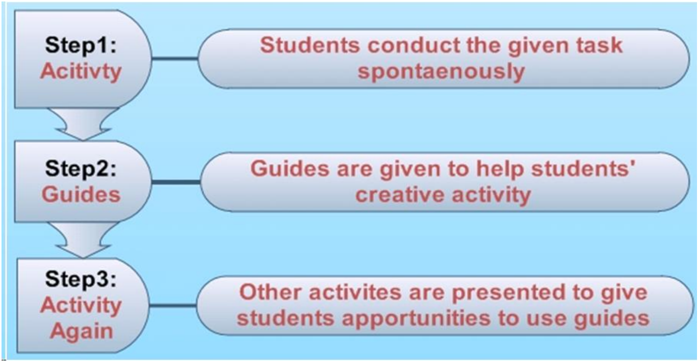

Figure 5. AGA^2 model for scientific creativity activity

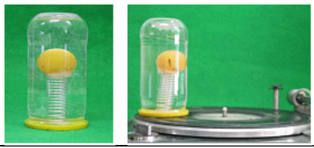
In the first step (Activity spontaneously), students are provided task to be solved, such as ‘revise the presented ordinary electroscope for more diverse usage’, ‘suggest various new scientific hypotheses to explain the observed phenomena’, or ‘suggest new and interesting situations which may show unusual phenomena’ as shown in Figure 6.

In the first step, students solve the tasks by themselves, that is, there is no any hints, guides, or aids for helping students’ solving activity. Therefore, some students can show high level of creativity by solving the tasks successfully, however, many others may solve the tasks in the level of common senses or in conventional ways, and also, some students may conflict difficulties in solving the tasks.

Ping-pong ball is connected by spring and inserted into transparent bottle with water. If it is placed on the rotating table, then you can see that the ball moves into inward direction which is different from usual situation.



1. Likewise, find out any other interesting situations which can show unusual results.
2. Explain the results why such unusual results are happened.

Figure 6. Activity in the first step of AGA^2 model

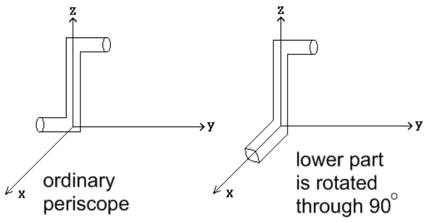
Therefore, in the second step, we provided actual guides which could encourage students' creative activity. In Figure 7, four basic guides are provided to help students suggest new unusual situations. Of course, these guides are not general rules for all types of scientific creativity but may be different according to the tasks. However, basic ideas of guides are closely related to creativity thinking in MSC. For instance, three guides provided in Figure 7 are basically to encourage 'unusualness' which is one component of divergent thinking. That is, in these guides, to encourage students to think unusually, they are guided to change ordinary structure or the assumed conditions, and to think reversely.

To find out unusual situations and to explain it, following guides can help you.

Guide 1: You can change basic structure. For instance, you can rotate the lower part of periscope as figure:

(1) Describe and explain what you observe using 'strange periscope'.

(2) Find out any other unusual phenomena by changing basic structure of ordinary periscope.



Guide 2: Now, you can also change the assumed conditions involved in the usual situation. For instance, when calculating the falling speed, we usually assumed that there is no air resistance. Then, you can think about the falling object in the air.

(1) Predict what will happen when air resistance acts on falling objects.

(2) Find out any other unusual phenomena by changing the assumed conditions in the falling object.

Guide 3: Finally, reverse thinking can also help you find unusual phenomena. For instance, usually convex lens made by glass is placed in the air. Then you can think convex lens made by air inside the glass.

(1) Describe and explain what you observe using 'air convex lens'.

(2) Find out any other unusual phenomena by thinking reversely in ordinary convex lens.

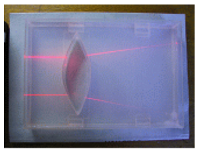


Figure 7. Activity in the second step of AGA^2 model

The final step is to apply the guides exercised in the second step to other new situations. In Figure 8, students are encouraged to apply the guides in finding out unusual phenomena using usual electroscope.

Now, find out any unusual situations in the usual electroscope by applying above 3 guidelines.

Figure 8. Activity in the third step of AGA^2 model

STUDENTS' RESPONSES ABOUT THE WORKSHEETS FOR SCIENTIFIC CREATIVITY

Recently, Park, Park, and Lee (unpublished) developed about 30 learning materials for scientific creativity based on AGA^2 model. These materials were classified into three categories: thinking creatively in scientific context, conducting scientific inquiry creatively, and understanding/applying scientific knowledge in creative ways. In the ‘Center for the gifted in Science’ in my university, I have applied the learning materials to the gifted students for several years and analyzed their responses to obtain the information about whether they enjoyed the scientific creativity activities, there were any difficulties in conducting the activities, the provided guides in the second step were affective for their creative activities, and so on.

Now, many data have accumulated and other research colleagues with me analyzed the data in different ways, but all analysis is not completed yet. Therefore, here, I would like to show some examples of results briefly. It is worth mentioning that some results examples are under more detailed analysis.

(1) Learning material shown in Figure 6 ~ 8 was used for nine students (7~8 grade, 13~14 years old) in ‘Center for the Gifted in Science’ (Park and Jee, unpublished). The second step and the third step activities were presented after completing the first step activity. It took about three hours to complete all three steps. From the analysis of students’ responses using the 5 Likert scale (5 point means highly agree, 3 means neutral response, 1 means highly disagree) questionnaire after the activity, students answered that even though the activities were not easy to them (average response was 2.4), it was interesting to them (4.0), it was helpful for them to understand scientific knowledge (3.6), and it could improve their creative thinking (4.0). As a result, they answered that they wanted to conduct this kind of activity in the future course (4.3).

(2) In the study by Park (unpublished), fourteen students of 7 and 8 grades were asked to generate various new scientific inquiry problems valuable to be investigated (Figure 9 is the first step of learning activities for generating scientific inquiry problems).

Two ring magnets are put into the plastic rod as shown in the photo. Because of repulsive force between two magnets, upper magnet is floating into the air.

After observing the phenomena, suggest various problems (questions) valuable to be inquired, as many and precisely as possible.

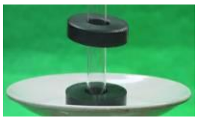

Figure 9. Problem situation used in activity

In this study, I analyzed how many and various inquiry problems were generated before the guides in the second step and after the guides.

As a result, in the first step, total number of inquiry problems (IPs) spontaneously suggested by students was 86 (average 6.1 per one person). However, in the second step in which guides for creative thinking were provided, the students suggested more 78 IPs (average 5.3 per one person) additionally. This means that the number of IPs suggested by the students increased by 91% (=78÷86 × 100). Comparing the total number of IPs with the initial number of IPs before the guides in the second step, the incensement is statically significant (t=7.4, p<.01). This means that guides in the second step could help students’ fluency (the number of ideas) which was feature of divergent thinking.

And we compared IP types before and after the guides for each student to check whether the number of IP types will be increased by guides. As a result, I found that total number of IP types was average 2.5 in the first step, but, it increased to 3.6 in the second step. That is, the number of IP types increased by 44% (=(3.6-2.5)÷2.5 × 100), and the difference of number of IP types between the first step and the second step was statistically significant (t=3.4, p<.01). This means that guides in the second step could help students' flexibility (various ideas) which was also feature of divergent thinking.

CONLCUSION

In this article, based on the assumption that scientific creativity may have different features compared to creativity in other areas such as literature or art and so on, the model of scientific creativity (MSC) is suggested. Of course, to understand the scientific creativity more completely, the role of personal characteristics such as openness, autonomy, or self-confidence and so on, the role of social, environmental, or educational supports, and/or the role of intrinsic/extrinsic motivation should be discussed more widely. Therefore, in the future research, other various and important aspects can be added to the MSC suggested in this article.

And also, theoretical model should be verified and applicable in various contexts. To do this, concrete many scientific creativity activities also were developed and applied to the gifted students in science. Here, I showed some examples of results about students' responses of the developed activities. In the near future, I hope that more detailed results about the effects of the developed activities on improving students' scientific creativity will be presented.

ABSTRACT

The aim of this paper is to present a science teaching strategy integrated in a wider project to develop, in Portugal, a kindergarten science curriculum with a Science-Technology-Society focus. Besides establishing the adequate science contents, process skills and scientific attitudes, it will develop a set of articulated practical activities (teaching, learning and assessment strategies) as well as the respective didactic resources (teacher's guide & materials).

At the present stage of the project ten different practical activities, regarding several science concepts, were designed. They were all validated in real-context by Kindergarten teachers who attended an in-service training program designed with the purpose of developing the necessary subject matter and pedagogical knowledge to support these educational practices.

Detailed presentation of one of these science teaching strategies (aims, guide, resources and assessment), will be made, as well as of its validation process and conclusions.

"Granny's toys and mine" is a context-based teaching strategy intended to engage kindergarten children (3-6 years old) in exploring concepts regarding the presence of science and technology in our daily lives, namely in toys. While placing a variety of toys in two different points of a given time line according to underlying criteria, children also construct upon prior knowledge to recognize the consequences of the evolution of science and technology.

Data from the validation process indicates that throughout the activity children demonstrated a functional understanding of some scientific inquiry processes as well as of related science concepts.

INTRODUCTION

The research community today shares the understanding that scientific and technological literacy should have an early start, as soon as in kindergarten, in a child-centered approach and in a socio-constructivist environment. This approach allows children to progress from a descriptive level of the natural phenomena they observe in their daily lives to an explanation level, and from personal and 'small' ideas to shared and 'big' ideas (Harlen & Qualter, 2004).

The reasons for early science education have been presented by a vast number of researchers (Harlen, 2006; Heshach, 2006; Keogh & Naylor, 1999; Charpak, 1996) arguing that it does undoubtedly contribute to scientific literacy. Moreover, science education can even be regarded as a right for everyone (Fumagalli, 1998), included in the right for education.

As far as scientific literacy is concerned, the STS (Science-Technology-Society) strands of the science curriculum have been regarded as the best way for school science to face the challenges of 21st century society (Acevedo-Diaz et al., 2003; Aikenhead, 2002; Membiela, 2001). Science and technology should be taught embedded in social contexts which are relevant to students, displacing its focus from concepts. School science should allow children to construct an authentic image about science and technology, about the way scientists work and about the role that science and technology play in the evolution of Humanity. Students should be prepared to critically interact with an increasingly demanding world, where social and ethical values should be considered when deciding and acting (both individually and collectively) on its problems and demands.

STS is therefore assumed as a strand that promotes students motivation both on science and on school science (Caamaño e Martins, 2005) developing positive attitudes towards science and science teaching.

At kindergarten level the emphasis should be placed on context based teaching, assuming it as a teaching setting where children can start simple interactions with scientific and technological issues, while engaged in sound, but nonetheless ludic teaching strategies.

Kindergarten children have shown to be very competent in science when quality education in this field is provided, as detailed by authors such as Saracho & Spodek (2008), Van Hook & Husiak-Clark (2008), Havu-Nuutinen (2005) and Hadzigeorgiou and others (2009). Learning activities should sustain and promote children's curiosity and enjoyment so that they develop a lasting interest in science.

Enquiring children who are led to explore the world in a scientific way are most likely to be science literate citizens who see science and technology in a positive way, understanding and making the most of its strengths and limitations. This will contribute to their understanding of the role played by science and technology in modern society, and how to use them critically to make society evolve in a sustainable way, based on human, cultural and social values.

Emphasizing the scientific and technological strain of modern society, the research community agrees on the need of science and technology literate citizens. The educational system must therefore give an adequate response to this global challenge, investing at the teacher, the curriculum and the resources levels (Eurydice, 2006).

Kindergarten curriculum must necessarily include a strong, consistent scientific dimension within a child-centered approach, such as Osborne & Dillon (2008) defend in their report to the Nuffield Foundation. It should promote the development of children's scientific ideas in a constructivist learning environment that fosters scientific and technological literacy, emphasizing science in the curriculum.

The current project was developed on a design-based research approach (Wang & Hannafin, 2005), as it identified authentic shortcomings of the educational system and associated them with subsequent actions to improve the status quo.

PROJECT RELEVANCE AND DESCRITPTION

Science curriculum in kindergarten is determined by the complementary influence of the three main axis of education in general: the *Kindergarten Teacher* (and his underlying education process), the *curriculum* and the *resources* available to implement such a curriculum. It is therefore understood that solid subject content and pedagogical knowledge are required of the kindergarten teacher (KT) to support the construction of the science curriculum he/she intends to develop with his/her class, fully supported by a range of teaching strategies.

National Portuguese Curricular Guidelines for KTs date back to a decade ago and since then an increased awareness of the role of early science teaching has taken place.

It is the overall purpose of the wider project to present a science curriculum based on the assumption that, in kindergarten, children must take an active part in learning situations that support both the investigative (skills and attitudes) and knowledge-based aspects (concepts) of science education.

To support such a curriculum, ten practical activities were developed, leading to the exploration of several concepts relating to *Materials and objects*, *Light, Force & motion* and *Living things*. They are all varied in their typology, in the didactic resources they require, their duration and intend to develop a wide range of specific and transversal competences while laying the foundations for a growing understanding of basic scientific concepts. Enquiry is regarded as a form of content and as a way to teach (Yager, 2009), focusing on children's understanding and requiring their scientific knowledge and enquiry processes.

KT is the mediator between the children and the resources, conditioning the learning and development outcomes. A specific teacher training program was developed with the purpose of empowering them with the ability to maximize the expected results.

Assessment to be made of the adequacy of the activity is to take into account data gathered from the developed teacher training program, in order to fully relate and understand all the implications. It is also to consider the input given by these KTs, which will contribute to better their potentiality as a means to innovate kindergarten science teaching.

The whole implementation process is to be repeated, in an interactive, iterative and flexible research process, with KTs who will not attend a specific teacher training program. This will allow for establishing their potential in sustaining the development of children's scientific competences, regardless of KTs specific training.

RESEARCH METHODOLOGY

In this paper a practical activity relating to the topic of materials, objects and technology, entitled "*Granny's toys and mine*" is detailed, along with the implementation process which led to its validation.

Activity description

"*Granny's toys and mine*" is a sorting activity, in which children are challenged to group different toys according to their views on the epoch they were built. Children are expected to build on prior scientific understanding, evolving to more precise ideas about the core concepts involved and the intertwined nature of both science and technology.

Competences development
This activity aims at the development of a wide range of scientific competences, as described by the examples presented.

- *Content knowledge*: (i) The diversity of materials available of natural and non-natural origin, (ii) the presence of growingly complex equipment and (iii) science and technology together allow for a growing diversity of materials and more sophisticated technology in toys.
- *Skills*: like observing, comparing, identifying differences and similarities, describing events and observations, inferring, interpreting information, questioning, thinking critically, notice change, communicate, evaluate and select information, construct argumentation, make decisions and work autonomously.
- *Attitudes:* like curiosity, showing interest in understanding the world, questioning daily events, considering ideas and opinions from others, willingness to consider evidence and to change ideas, perseverance and working cooperatively.

Teachers guide
Each teaching strategy comprises a teacher's guide, which presents and describes their objectives, the related concepts and the teaching, learning and assessment strategies. All are flexible, as far as their framework is concerned, allowing the KT to adjust aspects of its methodology to its own group of children, and presenting the following components:

Concepts – Allowing the KT to know which are used to explain the phenomenon;
Key-words – Those related to what they will observe and explore (*materials, natural materials, old, new, recent, modern, evolution, technology, science, mechanism* …);
Learning outcomes - Those expected to be accomplished at the end of the activity.
Didactic resources - Presenting what is needed to implement the activity;
Context-strategy - Describing the resources and respective activity. This intends to, on one hand, ascertain about the children's ideas on the subject and discuss them, and, on the other hand, set off their curiosity, contributing to a more motivated participation;
Framework - Presented as a flexible frame to explore the concepts with the children;
Questions – Allowing the KT to understand how he/she can stimulate children's thought and help them progress in their ideas;
Systematization – A phase at the end of the activity, intended to clearly organize the learning outcomes, and establish relations with other daily events.
Assessment strategy - Describing the resources and respective activity, along with the evidence the KT should look for in order to ascertain about children's mobilization and development of scientific attitudes and science process skills, as well of their understanding of the related scientific concepts.
Further activities – Some are presented, allowing the KT to consider related teaching strategies, as extension activities.
Communication – Is considered important while leading children to communicate to others (colleagues, classes, parents…) what they did and what they have learned;
Research – Is also recommended as a means to gather more information on the subject.

Teaching resources
The teacher's guide is accompanied by a pack of **didactic resources** which includes all the resources the KT needs in order to develop the activity with the children.

As a **context-strategy** (**Figure 1**), the pack includes a short movie made from different clips easily accessed through the internet. These depict scenes from the daily lives in the early 20th century (cooking, washing, transport, communication, etc) edited from old movies and even present-day cartoons. These scenes are easily associated with the children's grandparents, who most probably led lives like the ones portrayed in the movie.

For the development of the **practical activity**, the resource pack includes a set of 27 different toys (**Figure 2**), such as dolls, cars, balls, puppets, yo-yos and others. These can be placed into two separate groups, considering the underlying criteria: *material nature* and *attached technology*. After freely exploring the set of toys, children will classify them accordingly, debating their choices and rectifying them when required.

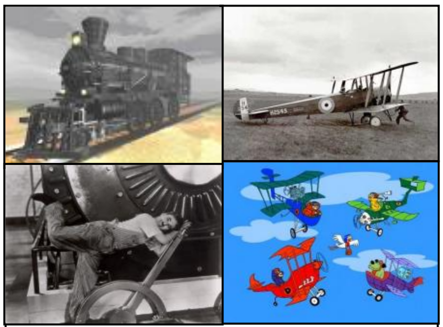

Figure 1 – Images from the context activity.

Figure 2 – The resource pack.

The toys that could have belonged to children's grandparents (**Figure 3**) are mostly Portuguese traditional toys, made of natural materials such as wood, raffia, leather, clay, and fabrics (like cotton, wool and silk) and also of metals (like lead, tin and iron). The more recent ones (**Figure 4**) can include materials of non-natural origin, such as plastic, rubber, silicone and synthetic fibres (like nylon, polyester).

Figure 3 – The set of "old" toys.

Figure 4 – The set of "new" toys.

The toys can also be sorted out by epoch according to their attached technology: the older ones' main purpose was to be set in motion by the child's application of a mechanical force (pushes and pulls resulting in slides, rolls, bounces…) whereas the most recent ones may also resort to magnetism, batteries or solar energy to cause movements, sounds, lights, etc. Implicit in all this is the fact that the most recent toys allow for a more complex interactivity with the child.

As an **assessment strategy** at the end of the activity, children are asked to match a two-by-two pieces puzzle (**Figure 5**), corresponding to sets of images showing the same object or structure built in two different periods of time (telephones, televisions, bridges, pens, lamps…). To do so, they are led to establish relationships between what was discussed up until this point and the images in the puzzles, transferring whatever knowledge they were able to construct.

Figure 5 – Puzzle for learning assessment.

Teacher training program

The developed teacher training program was entitled *STS education in kindergarten – Importance of experimental work*, and its aims were to allow KTs to (i) Understand the relevance and need of science education in the early years; (ii) (Re)construct subject content and pedagogical knowledge; (iii) Know international guidelines for science education – namely STS education; and (iv) Promote the development of adequate teaching strategies in kindergartens.

The practical activity detailed in this paper was validated by a KT who attended this 50 hour workload in-service training program, intended to promote the implementation of the 10 activities developed in this project. The 25 contact hours included theoretical (9 hours) and practical (12 hours) sessions, and a final four-hour group session intended to promote group interaction, leading to the discussion, analysis and reflection of the whole process and its outcomes.

Implementation session

"*Granny's toys and mine*" was implemented in a kindergarten located in the city centre of Mirandela, in the Bragança district (Northern Portugal). Although the KT chose to conduct the initial part of the activity with the whole group (25 children), the practical activity was later developed with a smaller group of 5 3-4 year-old children, taking approximately a total of two hours.

The KT preceded the suggested context strategy in the teacher's guide by another derived from her class previous experiences. A child's grandmother (granny Dulce) was asked to visit the class and talk about her childhood, bringing also some of her old toys and sharing memories of her childhood play. Those toys were later kept in the classroom, and children could explore them, with proper care. It was in granny Dulce's company that the class watched the video included in the activity resource pack (the **context-activity**), later discussing what they saw and comparing it to their present lifestyle. Once again, the grandmother was an important element to facilitate children's relation with a past time and lifestyle, as she impersonated it.

Throughout this talk, the KT promoted the discussion of children's ideas. She focused on the materials used to make the objects shown on the video and on the different kinds of toys represented, always trying to direct children toward the evidence of their answers.

In the practical activity (**Figure 6**) children were challenged to form two different groups of toys: those which could have belonged to their grandparents and those which could have not.

After allowing for a period of children's spontaneous manipulation of the toys, the KT engaged them in more focused observations, questioning them if a given toy could have belonged to granny Dulce. Children would observe it and think about what they saw on the video, about what granny Dulce told them about her childhood and about the facts referred to on the previous discussion of their ideas.

Throughout the activity children were asked to justify their choices, thus providing opportunities for the development of a variety of science process skills and attitudes.

Their answers, and the reasons presented to justify them, were discussed among the children, through heedful guidance on the KT's part that would contribute to conceptual scaffolding. She intended her questions to lead children to focus their attention on the toys' details which could help situate them in one of the epochs. This intended to allow them to gain and construct some meaning about the core concepts involved and to build knowledge from children-generated ideas.

After all the toys were placed on their respective sets, the KT promoted the discussion of children's ideas regarding what they did, leading to the **systematization** of the activity learning outcomes.

The KT then presented children with the puzzle pieces referring to the **assessment activity** (**Figure 7**), asking them to try and match the correct pairs. As they did this, they were asked to compare them, to try and explain the differences found between them and to explain why they thought those two pieces were related to each other. While promoting talk, as an active assessment activity (Weavers, 2008), this lead children to reveal their understanding about the concepts involved and their learning progress.

Figure 6 – Children manipulating a wooden bird and a magnetic drawing board.

Figure 7 – Children matching puzzle pieces showing two telephones.

Data analysis and results

The implementation sessions were audio-recorded and photographed, which, along with handwritten data, allowed for a posterior accurate transcription of the occurred events. Analysis of the didactic strategy was based on the evidence children gave, through their behaviour, performance and words, of mobilising the specific set of capacities, attitudes and values. Knowledge was ascertained considering their responses throughout the activity, and moreover during the assessment strategy, focusing on the matches they made and the justifications given for making them.

Throughout the activity, and relating to the existent resources, children gave evidence of mobilizing a set of skills, attitudes and values, while constructing new and more complex knowledge, as they later revealed on the assessment activity. Analysis of the whole process was focused on evidence children gave as to the mobilization of **science process skills**, **scientific attitudes** and **content knowledge**.

Regarding **science process skills**, when they were asked to *establish comparisons* among the different toys, children were required to *make focused observations*, trying to *identify differences and similarities* among them. They often did so not only by comparing the set of toys with their own, quickly determining which could be considered as the more recent one, but also recalling what granny Dulce showed them and talked about. Children also established relations with scenes depicted in the movie they watched, having recalled such examples to justify their choices upon placing a given toy in its respective set. They would often say "*Because I had such a tricycle when I was smaller*", "*Because my grandfather has a pen like that at home*", "*Because its like the one granny Dulce showed us*" or "*Because the car is like the one Charlot drove on the movie we saw, and its nothing like my father's car*".

Children mobilised their *communication* skills all through the activity, mainly by *describing what they saw and did*, but also by *sharing and discussing their ideas* on the subject. They have shown to be able to *construct argumentation*, albeit at an elementary level, when they recalled the aspects in the given toys which led them to choose the set they thought it belonged to. This was supported by the KT, who promoted children's talk, also as a means to develop their *reasoning skills*. This guidance and conceptualization main purpose was to allow children to evolve from mere description, and to engage them in higher stages of reasoning, while challenging unsuitable concepts and contributing towards the construction of more precise ones. Children also *used specific vocabulary* (key-words) to justify their choices (ex: "*That's too technological to be my grandparent's motorcycle*"; "*Scientists hadn't invented automatic escalators like those before*"), leading us to conclude that they were connecting it to their everyday lives and gradually building a range of functional vocabulary to stand for future situations. This is important to consider in a Vygotskyan perspective, which values the teacher's and children's communicative attitude throughout the activity as a means to enforce the child's conceptual understanding. While sharing and discussing their ideas and understandings children are engaged in a purposeful communication process, leading to the promotion of authentic language usage.

Children's actions and explanations throughout the practical and the assessment activities give evidence of being able to *interpret information* (focusing on either the toys details or on their 'reading' of the images of the puzzle pieces), *evaluate it* and *construct on it* to build more solid knowledge about the concepts involved.

The children's attention to the toys' details and the time they seemed to take in considering other's ideas, also suggests that while *making decisions*, they were also showing some sort of *critical thinking*. They often considered both the facts and their colleagues' ideas to make up their own mind as to where to place a given toy. Their effort to tackle their natural impulse to distribute the toys on their own was, nonetheless, visible.

Children also demonstrated to be able to *work autonomously*, both during the practical activity as well as the assessment one.

They have given evidence of *inferring*, mostly on the assessment strategy, having justified some of the relations among the objects illustrated in the puzzle pieces using knowledge accessed during the practical activity. When asked why he paired a wooden wheel (wagon) with a rubber one (car tyre), the child argued: "*We've already said that in the old days they could only use wood to build things*". Notwithstanding, throughout the whole practical activity children were observed to support their choices with knowledge drawn form granny Dulce's visit, the movie and information discussed throughout the activity.

Analysis of the implementation session of this activity was also focused on evidence regarding the mobilization and development of **scientific attitudes** on the children's part. These should be considered important not only in the context of school science at kindergarten level but also as a way to interpret and to interact with the world around them, as a science literate citizen.

KT's main focus should be to build on children's curiosity in order for them to construct new and more precise knowledge about the word. Throughout the activity, they revealed *curiosity* about aspects of the different objects at their disposal, and also about the situations depicted in the introductory movie. Their questions ("*Why does that train make so much smoke?*"), their remarks ("*That plane does not look like 'our' planes!*") and the attention they paid from beginning to end, allows us also to conclude about their *interest in understanding the world*, namely on the concepts involved in the practical activity.

Although rather young, some children showed to *consider others ideas and opinions*. This happened mostly due to the KT's care in promoting a debated discussion of both facts and ideas, insisting on asking children if they thought a certain idea was correct, and if so, why. They appeared to be able to analyze a given idea, and to give arguments for or against it, revealing *willingness to consider evidence and to change ideas*. This can be inferred when children were confronted with facts that didn't sustain their decisions ("*Yes, that truck operates on batteries, so it couldn't have belonged to my grandparents!*").

In both activities, (practical and assessment) children gave evidence of *perseverance*, as they showed continued effort and determination to accomplish the purpose of the activity, handling their doubts and insecurities. When faced with a toy which they did not know where to place, their reaction was to ask for someone's opinion (the KT or a colleague), in order to help them decide, not giving signs of resignation or frustration. This also leads us to conclude that these children were able to *work cooperatively*, as in no occasion we witnessed any altercations among them. They waited while others chose an object, considered where to place it and explained their choice. They listened to one another and respected the others' opinions when they differed from theirs, contesting them when they disagreed ("*Can't you see your grandmothers drawing board couldn't have been a magnetic one?*").

Other evidence to be considered in the analysis of the implementation session regarded the children's construction of **knowledge**, assessing the ideas they showed throughout the activity, and the choices they made.

Children demonstrated to have constructed some general idea about the *diversity of materials available to man, both of natural and non-natural origin*. Although they did not express themselves using these precise terms, we can assume they were able to construct some knowledge about these concepts, inferring from the choices they made throughout the activity and, mostly, the arguments they gave to justify them. Children would often give justifications like "*This is made of wood, so it could be granny's toy", or "This is plastic, so it could not*", leading us to believe that they established a simple criterion to separate them: the material they were made of. Children clearly focused their attention in this characteristic of the toys to choose the set they found to be the correct one: those that could have belonged to our grandparents (toys made of materials from natural origin and metals) and that could not (toys made of materials of non-natural origin).

Evidence regarding the children's understanding concerning the *presence of growingly complex equipment* in those toys was also observed, albeit they did not resort to this criterion to support their choices as often and as clearly as they did with the one presented in the previous paragraph. Nonetheless, they focused on mechanisms such as solar cells, magnets and batteries to exclude a given toy from the set of "granny's toys" ("*Do you really think your grandmother could have had a toy with buttons which make all those lights and sounds?*").

Again the KT had an important role in allowing children to be familiarised with some science vocabulary in order to describe and explain the concepts involved. Mainly because of the

KT's input did they use words like "science", "technology", "modern" and "scientist" when characterising some of the toys they considered to be recent ones. Although the underlying meaning that those words may have for the children remains to be fully determined, we can however assume that some meaning was constructed.

Therefore, considering the content that *science and technology together allow for a growing diversity of materials and more sophisticated technology in toys*, we can only infer that children were able to form some kind of understanding about the processes and nature of science. Realising that science and technology are embedded in our daily lives, in this case, in most of today's toys, children concurrently build on the understanding that science and technology serve a useful purpose in our livelihood. Furthermore, to have formed some elementary idea about the dynamics of science and technology evolution towards more complicated objects will have contributed for the development of children's positive attitudes toward science and technology.

CONCLUSION

As a starting point, we assume that, on one hand, good quality teachers, with up-to-date knowledge and skills are the foundation of any formal science education system and, on the other hand that innovative curricula and ways of organizing the teaching of science are required to improve the science and technology literacy levels of the next generations. The wider project in which the development of this activity is included aims at contributing towards the required changes in current science teaching at the kindergarten level, in the Portuguese context. Science curriculum is therefore considered as a continuum (Braund; 2008).

We were able to gather evidence that, on one hand, the developed teacher training program contributed for KTs to construct knowledge to support the developed activities, and, on the other hand, that these activities can be considered as a means to achieve innovative practices in science teaching.

The assessment of the practical activities was based on the analysis made by both researchers and KTs who implemented them in a design-based research perspective, generating knowledge that can be transferred to real-context and can inform practitioners and other designers.

As the one presented in detail in this paper, all activities were considered adequate teaching strategies and didactic resources for the development of the kindergarten science curriculum. The concepts where considered appropriate and relevant, leading children to mobilize a set of skills and attitudes that are, in a Vygotskian perspective, well within their zone of proximal development.

The aforementioned process provides empirical evidence that the implementation of a set of specifically developed science learning strategies, such as the one presented, shows that it is possible to promote a wide range of scientific competences (knowledge, skills, values and attitudes) that should occur in any kindergarten context. This concurs with recent research showing young children's ability to do science as being underestimated, and presenting kindergarten as an eligible context for science teaching.

Moreover, it shows that when engaged in teaching strategies which are embedded in contexts familiar to them, kindergarten children are able to construct ideas not only about the presence of science and technology in our daily objects, but also about the evolution of science and technology.

External relevant people, like granny Dulce, may prove to be an engaging approach to bring children to relate with society, as a mediator of their kindergarten experiences with the inherencies of the modern world.

This strategy showed positive results in providing children with some nexus to the adults' complex world, relative to the underlying articulate relations to be found between the socio-cultural and human aspects of life and science and technology.

Evidence gathered throughout the implementation sessions leads us to consider new teaching strategies that would allow children to deepen their understanding about the evolution of science and technology. They have shown to be able to place a given object in two distinct places of a time line (their grandparent's time and the present day). This suggests as a pertinent extension activity one where children would be asked to place several images of a given object (cell phone, television, vacuum-cleaner…) in distinct places of a time-line. The images would illustrate the object as it was built in different periods of time, representing the visual features that portray its evolution. Likewise, it would be important to elaborate on children's knowledge about this subject, developing a teaching strategy that would allow them to understand that there are objects today which simply did not exist, for example, in their grandparents' days.

Teacher training programs have limited impact when it comes to reaching the whole teacher community. It is therefore assumed as important, in the context of the present study, to assess the teaching strategies impact with KTs who will not attend such a program. We are basing on the assumption that these activities should be able to sustain the development of children's scientific competences, regardless of KTs access to specific in-service training programs.

Children should be engaged and empowered, as to develop into lifelong learners in science, hence the need to provide children with multiple opportunities for joyful explorations and discoveries in science.

ABSTRACT

Researchers on education for environmental education, EE, and education for sustainable development, ESD, have discussed the affect of student's life – experience on the students ability to develop action competence. In this study we want to investigate in what way an action research oriented environmental education contributes do develop a pluralistic view of sustainable development. The research object was the students' ongoing reflections and interviews. The data was collected logbooks, transcripted focus group interviews and transcripts from a teacher interview. In the beginning of the project many of the students reflections emanates resignation and dejection. But after a few weeks the action research process and the sensibility to the students reflections guided them into empowerment and also helped them to start thinking of strategies and actions for the future.

INTRODUCTİON

In 1992 my school was invited to attend a project called ENSI, Environment and School Initiatives. There were six schools from Sweden who participated in ENSI. The project was initiated in 1986 in OECD's Centre for Educational Research and Innovation (CERI). Our school attended the second period of ENSI, which ended 1994 at a conference in Braunschweig in Germany. There were 20 countries participating the second period of ENSI. Harriet Axelsson, the Swedish coordinator documented the action of the Swedish schools in her thesis (1997). Our schools' teachers taught about environmental questions before ENSI started, but our education had just been a transformation about facts around the situation in our country. We realized that if the students were to learn awareness of the environment we had to change our approach to education. Our involvement in the action research methodology started with a learning process about photosynthesis. The project started with one open question:" What is life?" Then the students' went on by designing experiments with plants to find out and understand what they need to live. A short summary is that the students learnt a lot about working practically with plants, and when they two years later were tested by the national evaluation their knowledge of Photosynthesis were solid. This is one of the reasons why I once again choose to investigate, in cooperation with a science teacher, how Action Research can contribute to develop a democratic education in science and sustainable development? *The second author is my supervisor* because this article is part of my thesis at Stockholm university.

BACKGROUND

Researchers on education for environmental education, EE, and education for sustainable development, ESD, (Chawla, 1994; Shuman, 1999; Almers, 2009) have discussed the affect of life – experience on people's ability to develop action competence. Chawla and Shuman pointed on early experience in childhood. Almers (2009) research- question was: "How do young people experience that they have developed aspects of action competence for sustainable development?" Her definition of action competence is; A willingness and capability to act for changes in individual life-style, as well as for structural changes of society, in a way that includes responsibility for present and future generations." (p. 278)

Almers points to 4 different motives for young people to be committed for the environment.

1. Emotional reactions initiating a wish to change and willingness to act
2. Longing for meaningfulness
3. A desire to feel comfortable with what you can contribute
4. Longing for spirit of community (fellow-ship).

These young people have been inspired to interest on environmental issues by parents, informal education in idealistic organizations and by other grown up people. Only one of the interviewees mentioned that a teacher had impacted on him. If we look at Almers' result, we see differences from Chawla's and Shuman's research on how experience of nature and environment in childhood had an impact. Kaplan's (2000) tell us that the most important factors in environmental engagement were: To feel competence to act in questions about sustainable development, to be motivated to act, and to feel that it makes a difference to be able to make changes in life. Kaplan suggests a way of teaching, where you shape structures for people to understand reasons of environmental problems, possibilities to make research around them, and to participate in groups, discussing how to solve those problems. Also Almer's research confirmed Kaplan's results and the importance of students' sense of ownership.

In my research I want to address the question, if there are possibilities to arrange an educational situation at school where students acquire action competence. My research relates to Öhman's pluralistic view of ESD, (2008).

In the Swedish curriculum (Lpo 94) we can read:

"Democracy forms the base for national school system and it is not enough to have knowledge about fundamental democratic values. They must be brought out by using democratic ways of working and preparing the students for active participation in a civil society".

Öhman (2008) claims that, if our purpose with education is to attain the proposals in the Swedish steering documents, then the only way to address the education is the pluralistic. What is the way he is advocating? The pluralistic tradition strives to emphasize different perspectives, views and values, which are treating different questions and problems about our world's future. To reach that aim we need to bring the environmental questions into the classroom, so that the students will have the opportunity to discuss them in reality. Then they can decide for themselves in which direction they want to take different messages further. Such discussions are an important part of the pluralistic education. This is the only way to give the students enough competence to make their own decisions on environment issues after their formal education.

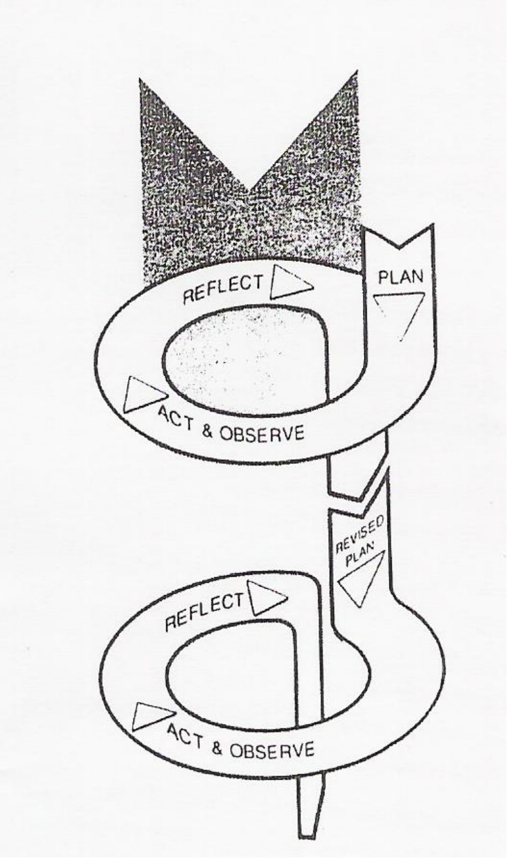
Action Research (AR)

Action research, AR, is being used in corporation and enterprising when the aim is to reach a change. Action research is described by Posch and Elliot (1994) in three levels.

Students are action researchers when they reflect over their learning.

T*eachers* are action researchers when they observe, reflect and change the education, develop professionalism.

The r*esearcher* is action- researching, when she/he is reflecting on what is happening in relation to the research question. In the school situation the teacher, researcher and the students plan action together, carry it out, observe what happens on the different levels and reflect on their result. The reflections perhaps identify new problems and then you have to start again from square one. The learning circle tries to explain the process.



Kolb&Fry (1975).

The Ensie- project (Posch 1991) was focused on the students' development of what they called dynamic qualities, competencies, such as initiative, independence, commitment to act and readiness to accept responsibility. The ENSI- project was based on the hypothesis that *environmental awareness and the promotion of these dynamic qualities are reciprocally related to each other,* Posch (1991 p.13).

AIM

The aim of this research is to investigate in what way Posch's elaboration on action oriented environmental education can be combined with a pluralistic view of Education for sustainable development, ESD.

Research questions
The main research question in this project is*:*
How can Action Research contribute to develop a democratic and action oriented education in sustainable development?

More concretely this study has focused on the question:
In what way can the students' reflections be used to develop an education sequence in sustainable development?

METHOD

Participants: the researcher, a science teacher and the students in year 9 at a secondary school situated in a suburb outside Stockholm city. The research object was the students' reflections in logbooks and interviews. These are paid attention all the way through the study. The researcher and the teacher will learn about learning during the whole project, they act as both subject and object in the study. The research data was: 1. collected reflections from the students' logbooks. 2. Transcripted focus group interviews from a student group on three different occasions. 3. Transcripts from a teacher interview at the end of the project.

After the students' reflections in logbooks and interviews, I transcript everything and after that the teacher and I discussed, how we should take care of the reflections in planning the next step in ESD.

We checked if the student group needed help finding more data about the subject they were studying or if they had some other problems in their groups. Then we helped them to solve their problems. At this stage we collected all written material and interviews. We did not only select some of them, because we wanted everyone of the students to go forward with their studies. In this article I only show some of the things the students made reflections on and later on in my thesis I will show more reflections, and how the teacher and I took care of them in our plans.

A.R. in the school practice?

The teacher got all the information, both oral and written about AR from me. I also informed her that my central research interest is around the students' reflections and not the teacher's action in the classroom. She was informed about the performing, that we were doing everything together on an equal level. We started together by planning the introduction for the students.

At the beginning we wanted to give the students a holistic view of the issues. Therefore we started the first lesson with an introduction on the environmental situation, both on a local and a global view.

The second lesson the teacher and the students had a discussion about in what ways peoples lifestyles have an impact on the environment; for example food, clothes and transports. After that the students got a question: *"What in your life-style and the impact of* *this on the environment do you want to investigate more?*" From this question they then created interest groups.

The first session was followed by a day at a museum and an exhibition called Global Change. The first question in their log- books was then: "*What was your experience of the exhibition and what were your immediate thoughts?"* The second question was: "*What do you think is the biggest challenge for human beings in the future?"*

Here are some reflections from the students:

" *There were so much information which was really interesting, but I was shocked. It was so terrible, what they showed in the film. More people ought to think about the future and just not ignore serious problems, just because they are not affected by them. (Girl 1.)*

"It was interesting to learn about all the things which impact our climate. It makes you realize how bad the situation really is. I thought it was terrible how we have destroyed the earth and made it an unsafe place to live in. More and more catastrophes are going to occur and more animals are dying out." (Girl 2)

" *It was not good that USA had not signed the Kyoto agreement. The life-style is going to change and you should be prepared for that even if you don't like changes. You have to do it anyway." (Boy 3)*

"*It was interesting and instructive, but it was also very frightening, because you really saw the difference now compared to 2000 years ago. I began to think about how the life will be for my grandchildren and great grandchildren - if they have to be floating on plastic boats because the ices are melting or if they dare not to go out because the ozone layer is disturbed and they are afraid of getting skin cancer*." (Girl 9)

" *We must do something with the environment. We must start driving environment friendly cars and stop the import of unnecessary articles from China, even if they are cheap because the transports are so long with carbon dioxide letting out." (Boy 4)*

As showed above many of the students reflections emanate resignation and dejection. This brought us to the decision to bring the problems up to another level, where the students did not have to feel so much individual responsibility. The teacher led a discussion about society's responsibility in economics and politics and about Individual organizations, which people can attend, to make impact on politicians.

After this the students in a more empowering way started to think in ways of actions, which make difference on the environment. Most of the students also connected the green - house effect to carbon dioxide and transports.

One question in the focus group interview was "Which is the most challenging question for the future?" Here is a short part of the discussion:

Ale: "*Economy is a barrier because it's difficult to start environment projects. They are so expensive in the beginning but later on they can be profitable."*
Fanny: "*Emissions, Take the step to travel by train or bus instead of cars. US can take the step, and then other countries might follow"*
Ale: "*It puts pressure on other countries"*
Fanny: "*People in western countries are worse and we have the most money but if we are doing the right thing and helping the developing nations –It will make a big difference"*
Peter*: "It would be worth going by bus or train, if they lower the prices. More people will use the local transport instead of cars."*

In this part of the project many of the students had begun to reach for solutions instead of only focus on barriers and hinders. Most of the students tried to find the solutions on transport questions and mentioned economy as a great barrier. They seemed to understand the green-house effect in relation to carbon dioxide emissions.

The final group works

After this short presentation of some of the episodes in the process I will just give a short presentation of what kind of recommendations the students have to help people create a better environment.

Two boys and one girl showed alternatives to cars, better public transport and those who had to go by car can choose ethanol - or electric motor cars. If you are walking or going by bike shorter distances, you also save the environment and you feel better, get healthier. The students finished by discussing the future, that the whole world must support the decrease of carbon dioxide. They presented an idea about producing bio-fuel from vegetable oils and vegetables from restaurants. They ended their power-point presentation with a beautiful bike with the text: "Help save the world - Go by bike!"

Two girls discussed *ecologic food.* They served ecologic lemonade for all the students to show them that it tasted as well as other types of lemonades. They had visited an ecological shop and also an ecological farm. They discussed prices on ecological foods and said that if more people were eating that food, the prices would go down. They finished off by showing *nice menus* with ecological food and the last picture showed a happy pig outside instead of being inside all their life. They ended with saying: "This pig is happy".

Two girls and a boy had studied the clothes impact on the environment. They talked about eco-clothes, poison and overconsumption. They had calculated how far the clothes had been transported around the world, before they get to the consumer and how much carbon dioxide outlet the trip had caused. They also talked about the textile industries in India causing 25 000 peoples' deaths each year because of all the poison in the clothes. Most of the clothes come to Sweden from China. In what way could we help to change the situation in the factories for those people? It's a moral, political and economic question. Would you like to buy more expensive clothes or is it okay that they are produced by children in dangerous factories, if they are cheap. We should shop for clothes with quality instead of quantity was their last message.

Three boys made a film, which all the students and the teacher and I found very funny, even if they had a serious message that people would afford to buy ecological food if they don't throw away so much food like they are doing today. They also answered questions from people phoning them and asking what kind of food products they recommended.

The last question in the focus group interview was "How can we together change the world to become a better place for future generations?"
Here is a short part of this discussion:

Ale: *By everything - everybody can do small things. You can impact both in practical and political ways.*
Fanny. *By trend-setters*
Ale: *Not only trends, you have to act in ethic ways.*
Interviewer: What about Al Gore? Has he got a lot people engaged? Even if he flew around Sweden and J (a girl in their class) thought it was wrong.
The group (in unison*): Yes. He was good*.
Albert: *You should not only talk!*
Fanny: *My parents say that, I am a NATO person -No Action Talking Only.*
Peter: *The politicians must be unified all over the world. Then the economics is no problem if everybody supports the same thing.*
Mark: We must act now and produce environmentally minded things like vehicles, industries and better fuels .The whole world must work together. It's too late in 30 years time, the glaciers will have melted.

Interviewer: Is the nature as important as the human beings?
Ale: *If there is no nature, you will miss it – The breeze in the trees, the wind and water*.
Peter: *All the other countries must get help – We need healthy nature both here and on the other side of the world.*
Albert: *When is the new Kyoto agreement coming?*
Interviewer: In Copenhagen there will be a large environment meeting in December this year- We will see what happens there.
Mark: *China and U.S. are most important!*
Ann: *Rich countries must help more. Everybody on earth must respect plants, animals and humans. The whole world must work together.*
Mark: *Nobody should ignore these important environmental questions. The whole world must help each other.*
Fanny: *All countries should take care of their own waste products and not transport it to other countries. They are not going forwards in that way. The rich countries should take responsibility and they have the most impact. Therefore they have the most influence.*

Another question all the students got in the end was: Can you now after this education follow the media debates around ESD and even make your own decisions in your first political election?

Ann said:" I wouldn't have been able to before this project, but now I am able to do it" The others in the group said:" Yes we are able to do it now. Another student said: *"Everybody should have the opportunity to learn about these things."*

SUMMARY

The concrete question was: *"In what way can the students' reflections be used to develop an education sequence in sustainable education?"* In the first reflection occasion the teacher and I had to meet the girls, who were worried about the future. The second time, we only checked up, if the groups needed help in some ways and we helped those who asked for help. On the third occasion we just wanted to check what they had learnt about the environmental situation in the world. We, the teacher and I, can say that it worked fine to follow the reflections and help all of them who needed help, because if they are working individually, they often don't want to ask for help in the classroom. I have experienced that the teacher get more reflections over the students' learning if they were given time to write down them. I also learnt a lot by listening both to the teacher and to the students and to be quiet and wait for the teacher's and the students' thoughts.

The research question was:" *How can Action Research contribute to develop a democratic and action oriented education in sustainable development?* "
In this research project the students were taking initiatives, planning and acting, as they developed their dynamic qualities (Posch ,page2). After that they were discussing in the logbooks and interviews about the challenges on the environment both local and global.
What about the question Almers asked (page 2) "*What possibilities have the schools got to arrange education in sustainable development to encourage students to act in environmental questions?"*

In this project I have showed that it is possible to do that, but I am not saying that you have to do it the way the teacher and I have done. What I can say is that a democratic way like the pluralistic way, where the process is student driven (page 2) is to recommend if you want to develop students' self-esteem.

How could the teacher and I see that the students had learnt about ESD?
In interviews and logbooks we saw how they talked about different environment issues, for example greenhouse-effect and how to limit it, and they thought about transports (p.4 and 5) and that showed that they understood some of the underlying reasons to that environmental problem. They also talked about the same thing in their reports (see p.5) and about saving

electricity at home. This was were we saw, that they were understanding the relation between fossil energy and carbon dioxide. In their final group reports we also found in the recommendations to class-mates, that they have got a deeper understanding of some environmental issues. We noted that they understood the global effect of carbon dioxide outlet when they talked about the Western Countries to help other countries towards a better environment (p.5,6). There are a lot of more things to analyze in my research about teaching and learning and about the action research and teacher sensitivity and I am thankful for the ideas I got from the reviewers, and I will have much use of them further on when I am writing my thesis. This article was mostly about the Education for Sustainable Development, but I will look later on at other parts of my research, so I agree that there are limitations in my study.

Referring to the *teacher's last comments*:

About students' progress:
"The work has been meaningful for all the students, as for the first time at school, have got a deep-sea diving in their own interest areas on environment questions. They have got a genuine insight and deepening in many environmental questions by their own work and the other groups' works. I was most impressed by the students' engagement on the topics they had chosen. They have been disciplined and worked all the time. Some students were ready before the others and they helped the other students' with power- point presentations."

About action research:
*"*When I think about this project I only have good thoughts about it. I have worked alongside the researcher and shared thoughts and ideas. I have felt confident, when the researcher has been in the background and supported me in questions, which I have not been so sure about. The students have felt that both of us were there for their sake, helping them when they needed it. I have learnt a lot too about ESD and also about that way of working".

In what way did the students reflect on their life-styles?
Some girls had started looking at where their clothes were from. Both the boys and girls discussed ecological food and about how to save electricity. The students seemed to be engaged in environment questions, and my hope is that they will go on learning more about environmental issues in future. They will do it, if Dewey (1916/2007) was right, when he said "if they get inspired now, they want to learn more in the future."

ABSTRACT

Due to their specific nature, science and technology are two fields that require a high level of technological equipment. The Faculty of Natural Sciences and Mathematics, which educates teachers of natural sciences and technical subjects, must therefore closely follow technological developments dictating a fast pace. It must further provide student teachers appropriate digital competencies that are inevitable when working with the young population. This article presents a research conducted among fourth-year student teachers of natural sciences and technology. The research was conducted in order to see how students evaluate the conditions of using the computer at the faculty, their opinions on the necessity of using the computer in class and digital competencies obtained during their studies. The results show that students are not satisfied with the computer equipment that is available at the faculty, while they at the same time have high expectations about digital competencies, as they believe that using the computer in class is very important.

Keywords: *science and technology, teacher education, digital competences.*

INTRODUCTION

The teaching methods and styles in the educational process changed through history and have always aimed at higher quality. In the last 15 years, computer use increased reflecting itself of course also in the field of education. In the field of education, the computer provides a broad range of applicability. In addition to its educational function, it also enables communication on various levels and thus the use of the term information and communication technology (ICT).

In June 2007, the Ministry of Higher Education, Science and Technology adopted the Strategy for the Development of the Information Society in Slovenia through 2010 (Si2010, 2007). The strategy aims to facilitate effective use of ICT to boost the country's competitiveness and productivity and provide a balanced social and regional development and improve the quality of life of the society as a whole and of each individual. The strategy also covers the sphere of education and research which are the main activity of universities. By including ICT, universities primarily raise the quality of their offer in the education market. The increased trend of implementing new technologies in educational institutions however increases also the inefficient and unprofessional use of these technologies. Great care needs to be taken in the implementation of modern technologies, as their excessive application can have the opposite effect. In preparation and implementation of e-material, guidelines such as professionalism, the educational and didactic design and technological implementation need to be considered (Dinevski & Lokar, 2006).

At the University of Maribor, the implementation of e-learning is in a very active phase but the actual utilisation of e-learning depends on each individual faculty. Faculties providing programmes for student teachers must pay special attention to the implementation of ICT in their study process. Education of teachers is namely the starting point in the knowledge transfer vertical (see Diagram 1).

Faculties providing programmes for student teachers are those that transfer knowledge and competencies to teachers.

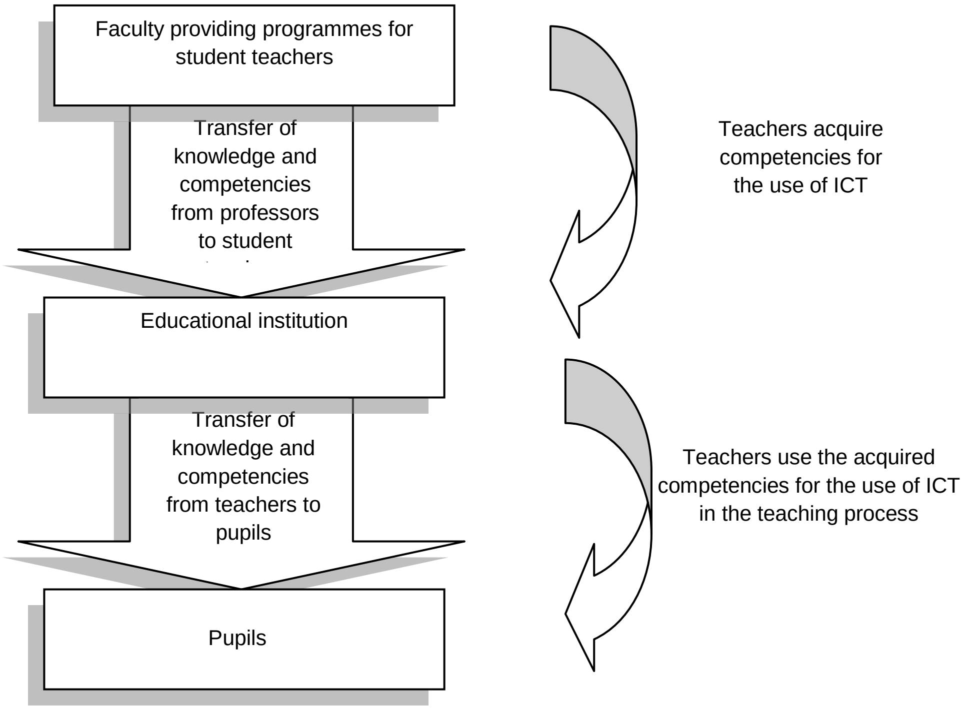

Diagram 1: Knowledge transfer vertical

Mastery of new technologies, especially information and communication technologies is a competency that has been added to the list of competencies in the last decade. Teachers, who have concluded their studies ten or more years ago, therefore did not acquire the required competencies during their study. For these teachers, corresponding training has been organised that has however not been provided separately according to individual subject areas. Another factor that is strongly related to the use of ICT in education is the field of teaching. Due to the specific differences of individual subject areas, the use of ICT strongly differs among teachers of different subjects. Our research has further shown that teachers of natural sciences, mathematics and technology and design are more receptive to novelties. Today's students are the so-called computer generation that grew up with computers and the rapid development of ICT. We therefore assume that the use of ICT in education should not represent a major problem. Nevertheless, prior to implementing ICT in the educational process, their eventual desires or even advice need to be heard. The paper presents the research conducted among student teachers of the fourth year of the Faculty of Natural Sciences and Mathematics. The results of the study present their opinions on the conditions of using the computer at the faculty and opinions on the necessity of using the computer in class and on the digital competencies obtained during their studies.

THE COMPETENCIES IN TEACHER EDUCATION

Lots of authors (Hermans, Tondeur, Vanbraak, & Valcke, 2008; Loveless, 2003; Ploj Virtič & Pšunder, 2009) have studied the use of ICT in education. They have predominantly shown that the decisive factor for a successful implementation of ICT into education is the teacher. This is a logical consequence of the fact that it is the teacher who directly performs the teaching process and at the same time the one who uses ICT.

Bitner and Bitner (Bitner & Bitner, 2002) researched efficiency of teachers in using ICT and have found that it is the skill and attitude of the teacher that determines the effectiveness of technology integration into the curriculum.

Ertmer (Ertmer, 2005) stressed the teacher or his beliefs about the transformative nature of new technologies as being the most important factor for the use of ICT.

The issue of students' ICT uptake in the classroom is of crucial importance, for it has been argued that use of ICT in teaching during school practice will lead to competent and confident in-service use, while lack of it will mean that future teachers will make little use of ICT.

Galanouli and McNair (Galanouli & McNair, 2001) researched student teachers' use of ICT on teaching practice and concluded that it is necessary for effective future use of ICT in the classroom. They report that there are a number of factors affecting the use of ICT by student-teachers in their school placements. One of those is appropriate digital competencies.

METHODOLOGY OF RESEARCH

The study reported in this article was conducted as a part of a post doctoral project "**Analysis of the Higher Education Technical Didactics and Creating the Application Framework for Transferring Technical Knowledge**", which seeks to evaluate the ICT implementation in teacher education. The research was conducted among students of natural science, technical and computer science, students of social studies and humanities; and students of the department of elementary education. This article focuses on students of natural science, technical and computer science. The article presents the student teacher part of the research, which explores the conditions of using the computer at the faculty, the students' opinion on the necessity of using the computer in class and the obtained digital competencies. The participants in this study were 87 students of natural sciences, mathematics and technology from the Faculty of Natural Sciences and Mathematics of University of Maribor in Slovenia. Data were gathered via an anonymous questionnaire. Research questions in the questionnaire were divided into three parts. We were interested in the opinion of student teachers of science and technology:
- on the conditions of using the computer at the faculty;
- in their expectations regarding the use of ICT; and
- in the digital competencies obtained during their studies.

RESEARCH RESULTS

Students' opinions on the conditions of using the computer at the faculty

In the first part of the research, we were interested how student teachers evaluate the conditions of using the computer at the faculty. We were interested if they see the conditions as supporting or hindering the use of the computer. We were interested in obtaining their opinion on the following conditions: availability of computers at the faculty, performance of computers at the faculty, software of computers at the faculty, internet access at the faculty and internet access in the town of study.

These conditions are probably the important factors influencing the use of the computer among students. The students used a five-stage scale to express their opinion on whether the conditions for the use of the computer are favourable or not. Statements relating to individual conditions were appointed numeric values from 1 – "I completely disagree" to 5 – "I completely agree". The more the students agreed with individual statements, the more they believe the conditions to be favourable for the use of the computer. The results are presented in Table 1.

Table 1: Mean of Rating Scores[a], Standard Deviations and Rank Orders[b] of students reporting on the circumstances regarding the use of the computer

Circumstances regarding the use of the computer	Mean	SD	Rang order
Internet-access in the town of study is well arranged.	3.6782	1.07286	1
Internet-access at the faculty is well arranged.	2.4253	1.17762	2
Software of computers at the faculty meets the study requirements.	2.1264	1.11860	3
At the faculty, there are enough computers available for study purposes.	1.8391	1.03287	4
At the faculty, the performance of computers is sufficient for study purposes.	1.6207	.81042	5

[a]A higher score indicates that students see an individual circumstance as more favourable for the use of the computer (1 = is not favourable for the use, 5 = is very favourable for the use)
[b]A lower rank indicates that students see an individual circumstance as more favourable for the use of the computer (1 = most favourable, 5 = least favourable).

On average, the students expressed a negative standpoint on four (out of five) statements. The only statement receiving a positive evaluation related to internet access at the town of study. This means that students see the conditions of using the computer at the faculty more as unfavourable rather than favourable.

They were least inclined towards the statements that computer performance at the faculty is sufficient and that there is a sufficient number of computers for study purposes. Software available on the faculty's computers and internet access at the faculty received slightly more favourable but still negative evaluations. Such results are undoubtedly not encouraging, as good computers and software can serve as one of the important starting points to motivate students to use computers for study purposes.

In the remainder of the article, we will briefly present answers of students of natural, technical and computer sciences compared to answers of students of social studies and humanities and students of the department of elementary education. The latter will find special discussion in a different article but as the results are interesting, we will partially present them also here. Results of the Kruskal-Wallis test have shown that compared to students of social studies and humanities and students of the department of elementary education, students of natural, technical and computer science provided the most positive feedback for all statements despite the rather poor inclination. This means than among all students they provided the most positive answers about the availability of computers at the faculty, their performance, software, internet access at the faculty and internet access in the town of study.

The reasons why students of natural science, technical and computer science were more positive towards the conditions of using the computer for study purposes than students of social studies and humanities and students of the department of elementary education are probably different. Let us mention only two that we believe stand out the most.

The first is undoubtedly that despite similar capacities available to students (all three faculties are located in the same facility), the nature of their study allows students of natural sciences, technical and computer science to have additional and well equipped computer classrooms at their disposal that they can per agreement use also outside the time of the actual study process. With all this, we cannot neglect another important fact. The nature of the study at the majority of study programmes at the Faculty of Natural Sciences and Mathematics also means that a study without the use of the computer is virtually impossible. Already due to the nature of their study, students of natural, technical and computer science are more proficient in their computer knowledge and use of computers than students of the other two faculties. This might help them to be more inventive in the use of computers and computer equipment and it is therefore possible that they would evaluate the given conditions of using the computer at the faculty more positively.

Opinion of students on the necessity of using the computer in class and on the digital competencies obtained during their studies

We provided six statements and asked the students to mark their agreement with each statement using a five-stage scale. Their answers are presented in Table 2.

Table 2: Mean of Rating Scores[a], Standard Deviations and Rank Orders[b] of students reporting on the necessity of using the computer and competencies

Competencies	Mean	SD	Rang order
As a student teacher, it is essential that I am qualified to use the computer in class.	4.5747	.69269	1
Today, use of the computer in class is necessary.	4.0000	1.07833	2
As a student teacher, I have sufficient knowledge to use the computer in class.	3.8161	1.01762	3
I have clear ideas on how to include the computer in class.	3.7586	.77708	4
Use of the computer is essential in subject(s) that I will be teaching.	3.5747	1.26337	5
As a student teacher, I have sufficient knowledge to use educational portals in class.	3.1839	1.10526	6

[a]A higher score indicates that students expressed a higher level of agreement with an individual statement (1 = I completely disagree, 5 = I completely agree)
[a]A lower rank indicates that students expressed a higher level of agreement with an individual statement (1 = I completely disagree, 5 = I completely agree)

It is evident from the table that students expressed a more positive opinion on statements relating to the necessity of using the computer in class than on statements relating to their competencies for using the computer in class. They expressed the highest level of agreement with the statement that as student teachers it was essential that they were qualified to use the computer in class and that today, the use of the computer in class was necessary. They agreed less with the statement that use of the computer was essential in subject(s) that they would be teaching. This statement was ranked only fifth. Even though the students expressed a lower level of agreement with statements relating to their competencies for using the computer in class than with statement relating to the necessity of using the computer in class, their answers are still encouraging. They indicate that students are optimistic about the knowledge to use the computer in class while at the same time have clear ideas how to include computers in class. They are however less optimistic about the knowledge to use educational portals.

CONCLUSION

We can all agree that the use of computers in the educational process is becoming increasingly important if not even vital. As said in the beginning, the use of the computer in class brings numerous positive results. It needs to be stressed that classes involving the computer are more interesting to the students and if they have the opportunity to use the computer themselves, the obtained knowledge is stronger and more permanent. We however cannot neglect the negative side of excessive application of computers in class.

Due to the necessity of using the computer in the modern educational process, teachers no longer need only conventional competencies but also knowledge and competencies of using the computer in class. Teachers decide whether to enrich their classes with ICT and numerous factors influence the teacher's decision whether to use the computer in class. Preparing teachers to use the computer in class already during the teacher training programme, possibilities of accessing computers and the equipment available to students play a major role. All this can stimulate or weaken the motivation for using the computer in class.

This study established the situation in this field. As the research included a smaller sample, its results cannot be generalised to the whole population. The research is nevertheless useful, as it helped us see to what extent students were using the computer, their viewpoints on the conditions of using the computer at the faculty and the digital competencies obtained during their studies.

The opinions provided by the students of the Faculty of Natural Sciences and Mathematics do not fill us with optimism about the conditions of using computers at the faculty. On the contrary, the results of our research have shown that students believe that a lot needs to be done in this area, especially with regard to improving performance of computers and increasing the number of computers available to students for study purposes. The students further believe that internet access at the faculty and computer software need to be improved in the future.

The opinions of students of the Faculty of Natural Sciences and Mathematics on the necessity of using the computer in class leave us with more optimism. This especially relates to their beliefs on the importance of using the computer in class in the modern world of technologies and slightly less to the competencies needed for the use of the computer that they have acquired during their study. This is another field with room for improvement.

Finally, we wish to point out that the study included only students receiving their education according to the so-called old university programmes. The situation with students studying according to the so-called Bologna study programmes still needs to be researched. Teacher educators are those that can influence the quality of acquired competencies by using a good strategy, while modernisation of computer equipment relates to financial funds that we unfortunately cannot influence.

AN ALTERNATIVE APPROACH FOR TEACHER EDUCATION COURSES FRAMED BY A COLLABORATE PARTNERSHIP SETTING.

Birgitte Schou Pontoppidan

Centre for Science Education, Aarhus University

bp@ivs.au.dk

ABSTRACT

The study presents an alternative didactical approach to teacher education linking practice and theory through *a collaborative partnership setting*. Using a "small scale" *teaching design* in which students alternate between schools and college it was possible to show some evidence that, by following this approach, first year student teachers in a science & technology class developed *teacher knowledge (as aspects of PCK).*

The study identifies an example using *Co-Re and PaPeR* as *a Resource Folio* to show where evidence of developing teacher knowledge is seen. This didactical approach turns the traditional teacher education on its head and begins with a focus on practice so students alternate between school–based and college–based teaching in a cyclical fashion, and are encouraged to link theory with practice. This kind of college teaching demands a new *teacher educational paradigm* for which collaboration between schools and colleges is paramount. This study indicates that a collaborative partnership setting involving college and *S&T- profile schools* can provide a "room for study", and that this kind of teaching design enhances the opportunities for students' to develop teacher knowledge (aspects of Pedagogical Content Knowledge) from the very start of teacher education.

INTRODUCTION

Linking theory and practice in teacher education is a challenge and international educational research has been dealing with this issue for many years. Partnership settings between schools and teacher education have been introduced to try and solve the problem (Furlong 1996).The Teacher Education programme in Aarhus (VIAUC) offers such collaboration, having developed partnerships with a number of training schools.

This study is a part of a larger on-going R&D-project concerning several approaches relevant to this partnership setting, and focuses on the possibility of offering "room for study", and so the opportunity for students to develop teacher knowledge, within the partnership setting. The aim is for the student teachers to be able to integrate college-based and school-based knowledge from the very start of their education in a way that makes it possible for them to develop the professional knowledge required for teaching, pedagogical content knowledge (PCK) (Shulman, 1986). However a collaborative partnership setting is a huge and complex frame for students, college teachers and mentors to work in, especially in a country like Denmark where there is little experience of this kind of set up in an education context. For there to be "room for study" within the partnership setting it will be necessary to develop alternative course designs for the student teachers, that provide suitable examples of didactical approaches so the student teachers have the opportunity to develop PCK as a result of the integration of college-based and school-based training.

This article sets out to provide an example of a possible design for such a teacher education programme that uses the partnership setting as “a room for study” within the collaborative frame.

Research question

Will there be evidence that an alternative course design framed by a partnership setting supports the students’ development of aspects of PCK?

I will begin by looking at what is actually meant by teacher knowledge in terms of PCK. I will then describe briefly the conditions of the partnership setting that are relevant for this case study. Next I will present a didactical approach to college-based and school-based teaching in the form of a course design that exploits the “room for study” in the partnership setting. Finally I will present some evidence that this approach to teacher education offers student teachers the possibility to transform different knowledge types by integrating college based and school-based learning and so start to develop PCK.

What kind of knowledge is the teachers’?

In traditional teacher educational settings teacher knowledge is believed to develop through the college-based and school-based teaching and training. The fields are usually taught separately and the integration into usable teacher knowledge has to a great extent been left to the student teacher’s own initiative. This has often proved to be difficult because according to the special teacher knowledge, ideas and theories that influence student teachers’ understanding of the link between theory and practice, this link is often tacit (Schön 1983, Korthagen 2001, Gess-Newsome 1999).

Teacher knowledge as PCK has been discussed in international educational research for the last twenty years (Berry et al. 2008), starting in 1986 when Lee Shulman (1986) defined special teacher knowledge as a construct of PCK that included,

“the most powerful analogies, illustrations, examples, explanations and demonstrations – in a word, the ways of representing and formulating the subject that makes it comprehensible for others....
…that special amalgam of content and pedagogy that is uniquely the providence of teachers, their own special form of professional understanding…Pedagogical content knowledge.... identifies the distinctive bodies of knowledge for teaching.. (Shulman, 1987, p.8)

After twenty years of Science Education Research teacher knowledge as PCK has been interpreted and elaborated by several researchers (e.g. Gess-Newsome, Appelton, Van Driel, Hashwey, Loughran, Abell). They have focused on different aspects of PCK, but there is a common opinion about four important characteristics of this kind of knowledge: PCK includes discrete categories of knowledge that are applied synergistically to problems of practice; PCK is dynamic, not static; Content (science subject matter) is central to PCK; PCK involves transformation of other types of knowledge (Abell, 2008, p. 1407). These four important characteristics of PCK and the synergistic view that PCK is more than the sum of its constituent parts will be the main analytical frame for this study.

As mentioned above teacher knowledge is a different kind of knowledge to its constituent knowledge types. Korthagen et al. (1999, 2001) try and make the distinction by referring to the knowledge types defined by the ancient Greeks such as Aristotle: Episteme and Phronesis. Episteme knowledge, in this context called theory with a capitol “T”, is based on research and the type of knowledge that is central to the field of teaching in traditional teacher education: Subject matter (e.g. biology), “Fachdidaktik”, Pedagogy. But more often student teachers need knowledge that is situation specific and related to the context in which they meet a problem, this type of knowledge is Phronesis, in this context named as theory with a small “t”, that is a more perceptual knowledge than conceptual (Korthagen 1999, p.7). So, teacher knowledge as explained above is theory with “t” with a foundation of theories with “T”, practical knowledge, Techne (praxis), and other things (e.g. ethics, emotions, tacit knowledge). All this is well illustrated by the “amalgam” metaphor (Shulman quotation above). Teacher knowledge is not a kind of knowledge that can be studied in a book, it is to be experienced and interpreted through reflections - in - action and reflections - on - action (Schön, 1983). Hashweh states that:

” We should stress....that PCK is knowledge associated with experience, and does not seem to develop from studying in pre-service teacher education programs, at least the traditional ones” (Hashweh, 2005, p 279)

Considering the knowledge types an alternative approach to teacher education would be to turn the existing college-based teaching approach on its head and start from practice and end in theory, as described in “The Realistic Approach to Teacher Education” (Korthagen et al. 1999, 2001, 2006).

“...the keyfactors is the relation between the schools in which student teaching takes place and the teacher education institute. Both staff based at the teacher education institute and cooperating teachers are part of one team that supports the professional development of student teachers” (Korthagen, 2001, p. 78)

Changing from a traditional teacher educational setting to an alternative approach, in which the focus has shifted to the students’ integration and transformation of different knowledge types requires the development of new content for the college-based training elements of the education programme. In addition it is important to consider the collaboration with the schools and the mentors as they will be the key to the whole approach as noted above (Korthagen, 2001). The conditions framed by a partnership setting will influence what opportunities student teachers have for transforming the different knowledge types into PCK.

The Partnership Setting

This Partnership setting is an agreement entered into by the training schools, the teacher training college and the municipality. In addition to the field experience period the partnership schools are obliged to involve the student teachers in other relevant activities including observations of teaching and pupils, parent meetings, staff meetings, school parties, etc. throughout the entire school year. The school-based mentors also have to take part in several meetings at the teacher training college during the year of study including planning meetings, and they are expected to take part in the preparations for the practical as well as the theoretical part of field experiences. Over all this partnership approach is very much in line with Furlong’s description of a collaborative partnership arrangement:

“For the partnership to succeed mentors and college teachers will need to plan some educational settings together in an ongoing collaboration to develop a programme for the student teachers that is integrated between college and schools “(Furlong 1996, p. 44)

However the didactical approach to the partnership setting is general and complex - one could describe it as “boulder size”, and one of the challenges will be to develop new approaches to the teacher training programme - at “grain size”. Teaching designs that have a “grain size” focus with an emphasis on the student teachers’ way of planning might prove to be a central issue for the partnership collaboration. Hashweh’s interpretation of PCK as a collection of basic units called Teacher Pedagogical Constructions (TPCs) is a reasonable framework for this kind of small scale teaching design (Janssen et al., 2008). Planning, according to Hashweh, is central to the development of TPCs and thereby to the overall PCK development.

“Teacher pedagogical constructions result mainly from planning, but also from the interactive and post active - phases of teaching” (Hashweh, 2005, p. 277)

This article presents an example of a small scale teaching design for college-based teaching, and is inspired by Janssen et al.’s 2008 study among others. Janssen et al. explored a domain-specific heuristic for lesson planning and showed the usefulness of cyclical processes alternating between school practice and college teaching.

It would be reasonable to assume that for first year students incipient PCK could start by developing TPCs or aspects of PCK. For this to happen the college-based teaching and the school-based teaching need to be integrated by taking advantage of small scale teaching designs that alternate between schools and college and offer the students an opportunity to develop teacher knowledge.

Resource Folio

Central to the teaching design is the use of a Resource Folio as a “tool” to help the student teachers bridge the gap between college-based and school-based teaching. The Resource Folio were originally developed by Loughran, Berry, Mulhall (Loughran et al. 2004, Loughran, Berry and Mulhall, 2006) as a method for exploring and representing expert science teachers PCK. The Resource Folio consists of a Content Representation, Co-Re, that represents the structured planning of the teaching and includes several points the student teachers must be aware of when teaching specific content (using knowledge about science and learners to make curricular decisions and using knowledge about science and learners to make instructional decisions) and a Pedagogical and Professional-experience Repertoire, PaP-eR, that is a complementary narrative which includes reflections on teaching. Together they are referred to as the Resource Folio (Mulhall 2003)

In this setting Co-Re is used in a slightly different way:
First as a “reverse engineering project” to make the students understand how to start building up aspects of teacher knowledge, drawing upon Subject matter knowledge (SMK), educational theories according to pupils learning, lesson planning, evaluation and so on. The elaboration of the Co-Re is meant as a basis for the further planning of the teaching sequence.

Second as a meta-theoretical approach to teaching, which was tried out by Loughran et al. (2008), who showed that it is possible to make student teachers aware of the existence of the different knowledge types in PCK.

Teaching Design

The design of the course outlined below shows an alternative didactical approach to college-based teaching in Science & Technology to enhance student teachers’ teacher knowledge. The topic is the blood circulatory system – a teaching sequence lasting for two weeks. The design alternates between school-based and college-based teaching and the different steps relate to the numbers in fig. 1.

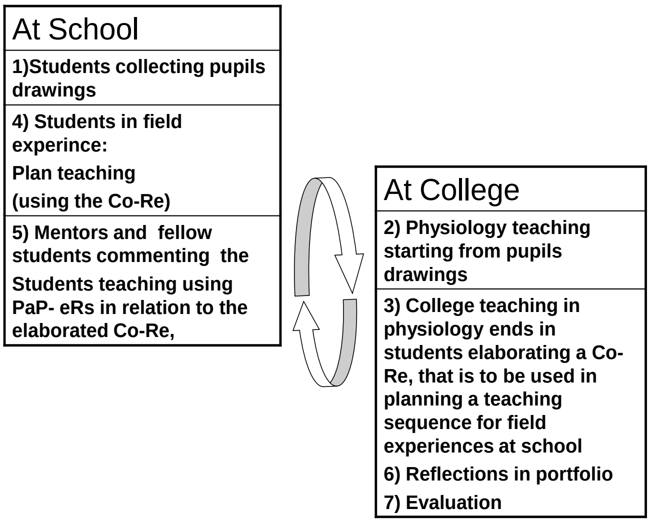

Fig.1, The cyclical process of the study alternating between college teaching and school practice.

1. The teaching sequence started in the school where the student teachers were supposed to identify some of the learning issues (Millar et al., 2006) that can arise when pupils try to understand their blood system. The student teachers asked the pupils, who ranged from 1st to 9th graders, to make a drawing of the circulatory system on a full size drawing of a body outline
2. The drawings were then presented and discussed at the college.
3. SMK according to the topic was taught at college, and the educational theories considered the drawings in particular in respect of the learning demands (Millar et al., 2006).
The student teachers' assignment was to plan a teaching sequence for Science & Technology that they could use in their up-coming field experience period. To be able to do this, the students had to elaborate a Co-Re based on a group discussion - the same group that they were to join for field experiences.
4. The next step for the students was to try out the teaching sequence during the field experience period. The students practice in groups of two or three and fellow students and mentors keep a diary as a narrative for reflection in the form of PaP-eR (Loughran et al., 2002) or portfolio.
5. An important part of the field experiences are the student/mentor conference meetings where the mentor discusses the students' reflections on their teaching sequences and the teacher professional competences they have demonstrated during the period. The mentors had agreed to give the students supervision in relation to the Co-Re. Mentors always keep a diary of the students' teaching if not a PaP-eR.
Theories with "t" are prevalent here.
6. Back at college the student teachers present the main points from their field experience period according to the Co-Re /PaP-eR reflections. The college teachers build upon the mentors' 'supervision by adding theories - mostly ("T") e.g. fachdidaktik, SMK and pedagogical theories.
7. The last part of the teaching design is for the students to reflect on the teaching in relation to the Co-Re at college after they have completed the field experience period. The students are supposed to write reflections in their field experience portfolios for the mentor and the college teacher to read and comment on. It is compulsory for the students to create this kind of portfolio, which has been selected as the overall evaluation tool in the partnership setting.

With this approach college teaching starts with the introduction of different kinds of theories ("T") from which the students can begin to elaborate the Co-Re. The elaborated Co-Re represents the discussed theories relating to the teaching sequence that the students are supposed to teach during the field experience period. The theories with little "t" are not relevant before the field experience as they relate to the student teachers' experiences, and therefore the Co-Re is meant to be corrected and commented upon during the field experience period. In this way the Resource Folio represents the connection, "bridge", between the college-based and school-based training - placed in the partnership's "room for study".

Methodology

This particular study deals with the teaching of human physiology, which is part of the "Science &Technology" segment (a STS-subject for pupils aged 7 – 12 years). The participants in the study are first year student teachers who have selected the Science & Technology class, and who will teach "the blood system" during their field experience according to the Co-Re elaborated during the teaching sequence at the college. Five students and three mentors were involved in this particular study. The rest of the Science & Technology class had other topics to teach during the field experience period and made a Co-Re related to this other topic, and will not be a part of this case study.

Because this teaching design has been developed during the college teaching period by the researcher herself, there is a need for a flexible research design (Robson, 2002). As a consequence the study has an entirely qualitative research design, and the data was collected from observations of student/mentor meetings, interviews with mentors and student portfolios – various methods were used to promote triangulation.

Table 1 summarizes the data collected and for which purpose: One observation with three students and two mentors and one observation with two students and one mentor. The mentors took part in a semi-structured interview (Kvale, 1997) after the observations. Both observations and interviews were audio taped and transcribed.

participants	Data source	Timing of data collection	Purpose
Students	Observation	March 2009 Weeks no. 12 -13	Prompts revealing types of knowledge and reflections
	Presentation	Week no. 14	Prompts revealing reflections using Co-Re and Pa - PeR
Mentors and Students	Observation	Weeks no. 12-13	Prompts revealing the student learning of teacher professional concepts by using Co-Re as the subject of conversation.
Mentors	Interview	Week no. 12 -13	Co-Re as a "tool" for collaboration in the partnership setting

Table 1 Details of data collection

In this study I am trying to elucidate if an alternative course design in a specific teacher education situation supports the student teachers' development of certain aspects of PCK, when framed by the partnership setting. The theoretical framework for analyzing the data is first of all the four characteristics of PCK identified by Abell (Abell 2008) as described above. But by taking the incipient PCK into consideration as well as particular aspects of the PCK, TPCs (Hashweh 2005) will also be part of the framework.

In this paper I am just trying to identify examples of where there is evidence of developing teacher knowledge (TPC or aspects of PCK). As there is still data to analyse, I have decided to focus on one student teacher to see what knowledge is being developed according to the analytical frame mentioned above.

From observation 1 I have recorded a conversation between student (A) and the mentor (X) that illustrates A's reflections on practice and developing TPC for the topic under discussion:

A: "…our goal is not that the pupils are supposed to describe the total blood circulatory system when we finish this topic. But they are supposed to know that the heart pumps blood and that we breathe. I know that we teach much more than this in class because it is meant for the bright pupils."

X: "There is no doubt that after the very intense teaching sequence about (digestion (prior topic)), where the pupils have been extraordinary interested and engaged they will not be able to show the same enthusiasm continuously. The heart dissection you made today did not have the same appeal though they were totally engaged in the dissection. But it was difficult for them to imagine how the blood is supposed to run through the heart because it is not there, and they can not see the heart pump. That might be the reason why the pupil engagement was not as great as during the last topic"

A: "That is what I am reflecting upon. Perhaps this topic should be for 5th – 6th form instead - but the curriculum states that it ought to be 3rd – 4th!."

X: "You could probably break the goal up into minor parts?"

A: "Yes it should only be simple things to support the pre-conceptions. I will try to reduce this before the next lesson. Perhaps we should rethink our Co-Re"

(A) has obviously experienced that theories "T" and preparation based on these do not always fit with the reality, and neither does the curriculum. It also shows the reflection process that makes A rethink the planning because of the learning demands connected to this topic were different compared to another previously taught topic.

(B)

The conversation shows the usage of theories such as SMK, fachdidaktik and professional knowledge on the basis of experience. Though it is experience shared with the mentors and the fellow students, student A shows the ability to reflect upon his planning (referring to correcting in the Co-Re), which is one of the criteria for TPC development (see Hashwey quoted above). A also shows the ability to reflect upon a teaching sequence using theories "t".

A ends this particular conversation by saying:

A: "It has been a good "discussion platform" e.g. this discussion about the different hearts (animal types). One can make mis-judgments about the children's ability for learning the subject in a certain way but the Co-Re made us focus on the theories of Piaget and discuss the dilemma of the demands from the curriculum – so now we refer to Vygotsky and we will see when the pupils have made the last drawings (evaluation tool *ed.*) if we have been scaffolding enough."

This prompt illustrates that he is able to integrate Theories "T" as well in his reflections. He demonstrates that he is capable of meeting the four important characteristics of PCK (Abell 2008)

(The relation between the outtakes from the conversation to the noted characteristics is bracketed):

- Discrete categories of knowledge that are applied to practice *(SMK, curricular knowledge and pedagogy are applied in the reflection on practice).*
- That PCK is dynamic *(The corrections of the CoRe and after initially referring to Piaget he then finds Vygotsy's theories more appropriate).*
- That Content is central to PCK *(Previous topic easier for pupils to understand than the blood topic).*
- PCK involves transformation of other types of knowledge *(Theories with "T" and "t" have been reflected upon in the dialogue with the mentor).*

The two mentors are recognizing the Co-Re planning and X mentions in the interview afterwards that he thinks it is suitable to collaborate within the partnership setting between school and college:
(From the interview guide)

"Do you think it is worth proceeding with the work with Co-Re and PaP-eR as collaboration between college and schools?"
X: "Very good tools and it might be possible to make it "more Danish". As a part of the college teaching it is perfect because you can also use it when the education is finished and you have well planned and reflected teaching sequences in your "bank"."

CONCLUSION

What I was looking for was a new didactical approach to college teaching - that is well suited for collaboration between schools and college using the partnership setting as, figuratively speaking, a "room for study" and somewhere for the student teachers to begin developing their PCK. The idea was to concentrate on a "small scale" teaching design making it possible for first year students to have a chance to begin building TPCs or aspects of PCK as a basis for further PCK development during the rest of their education and in their practice as teachers.

Though I was only able to use selected conversation segments from one student teacher to show there is evidence of developing teacher knowledge, these excerpts seem to support the main idea in this article: That the use of Co-Re and PaP-eR in a "small scale teaching design" that alternates between college and schools might be a way to enhance student teachers' development of aspects of PCK. This kind of college teaching requires the evolution of a new teacher education paradigm, as it turns the traditional approach to college teaching on its head. By linking theory with practice, so that the initial focus is on the practice gained as the student teachers circulate between college and school experience site teacher education could be improved considerably. There are indications in this study that a collaborative partnership setting might constitute a "room" for this kind of teaching design and thereby enhance the students' development of aspects of PCK – collaborative partnerships could therefore be considered as a "room for study".

CONSTRUCTING PHYSICS EDUCATION IN DIFFERENT CONTEXTS: CHANGING CONTEXTS – CHANGING VALUES

ABSTRACT

This paper presents an analysis of how changes in the socio-economic context of an educational system affect the value base of the physics education embedded in this context. Based on the assumption that physics education is a socially constructed phenomenon developed within a particular socio-historical context with particular types of social relations, this study aims to highlight the features of physics education that are most sensitive to changes in the macro-context. In this paper empirical material was gathered from two countries (Laos and Russia). In both countries dramatic economic changes have taken place since the end of the 1980's, however, Laos has maintained the same one-party rule political system while the Russian political context has changed significantly. These countries also belong to the different cultural contexts of East and West, the consideration of which can contribute to an understanding of the corresponding value-base reflected in physics education. The qualitative research methodology used in this study includes data gathering through document and statistical report analysis, personal ethnographic experience and interviews with physicists and physics educators. It is argued that changes in educational values are not only discussed and experienced but actually created within physics education institutions in these countries against the backdrop of the macro-contextual changes taking place over the last twenty years.

Keywords: *Laos, macro-context, physics education, Russia, values.*

INTRODUCTION

The issues of developing human capacity and increasing the scientific capital of countries are actively discussed by politicians and academics around the world. Many countries have as a strategic goal the development of a knowledge-based society. The governments make investments in the creation of a critical mass of researchers in specific scientific fields. Universities also purposefully invest in building up research schools and creating successful research niches. Different countries have different traditions and conditions for promoting academic and applied research in certain fields. For example, the Soviet Union has been a real "science powerhouse" with a very high status in science from the time of the launching of the first Sputnik satellite. Many bright physicists and mathematicians were fostered there. Just to give an example, two out of four Fields Medal (considered to be the Nobel Prize of mathematics) laureates in 2006 were Russians, one graduated from St Petersburg University (Perel'man) and one from Moscow University (Andrei Okoun'kov). Both of them had been actively working in the field of theoretical physics and valued highly the importance of 'physics thinking' for their achievements in mathematics (ICM, 2006). They were brought up in the well organized Soviet system of physics and mathematics education that fostered solid science knowledge and creativity, particularly in gifted children.

However, educational institutions and researchers do not operate in a vacuum. People's choices, values and motivation depend as much on their working and living conditions as on the status and respect they are afforded by society. Grigori Perel'man, who was awarded the Fields Medal for solving the famous Poincare conjuncture, declined the medal and substantial economic award as a protest against the current situation in science in modern Russia. Dramatic changes in the Russian society in the period after perestroika led to new political priorities and economic conditions and as a result to new values and aspirations for society. According to a survey study conducted in 2006, to be a scientist in Russia today is regarded as one of the less prestigious professions (Adams, King, 2010).

The post-Soviet changes of the 1990s affected not only the Russian academic system but that of many countries around the world. In a review of national research systems in developing countries, Mouton and Waast (2009) show that research is no longer seen as a rewarding career there. The adoption of 'liberal' economic policies in poor countries, under the oversight of the International Monetary Fund, has led to restrained state spending in social and non-productive sectors. Researchers find it almost impossible to make a living and support for their immediate families. They have to take extra jobs unrelated to their research, undertake overtime teaching, or search for work in richer countries. Mouton and Waast (2009) suggest that the restoration and improvement of national research capacity in these countries requires a strategy that focuses on institution-building interventions rather than on individual scientists. Such strategies have been successfully implemented in some Asian countries. The Eastern cultural tradition of nurturing collective development has proved to be effective for promoting a rapid expansion of research. Governments that pay attention to national scientific capital also pay their researchers well. However, such factors as the power of trade unions, type of economy, cultural and intellectual traditions and the capacity of educational system cannot either be neglected. A country's investment in scientific research is usually paralleled by an investment in science education.

The hypothesis that we would like to explore in this paper is that changes in national economical and socio-political contexts strongly affect societal values, the production of scientific research and the construction of science education in the country. This hypothesis will be examined in the case of the two authors' native countries Russia and Laos and the focus will be on our professional field of physics education.

THE ACTIVE ROLE OF THE CONTEXT

Context plays an important role in peoples' lives. There are embedded background assumptions in everything that people do or say that are discernable only through the context. It is possible to state that human intelligence is context-sensitive. Researchers like Russell (1992) claim that context is of such importance in epistemology that there can be no inference or knowledge without it. It appears to be a basic building block of knowledge and its processing. It can be argued that without context there is no knowledge or knowledge processing (Russell, 1992).

The problem with context is that there is as yet no universally accepted definition, nor any comprehensive understanding of how to represent it or how it affects knowledge processing. A context consists of a set of things with specific and consistent relationships between them. The Latin root of the word context, *contexere* means 'to weave together' or 'that which gives coherence to its parts.' The relations and events that actually comprise a context can only be revealed by experience. Context is an open-ended and unbounded thing that according to Russell (1992, p.323) obeys a Heisenberg Uncertainty Principle and the act of perceiving it changes it. He underlines the importance of considering the depth and uncertainty of context in the analysis of human behaviour. Shanon (1983) suggests that context should be regarded as an interface element between the internal and external worlds.

Vygotsky (1978) considered context to be an active component of the educational process that interplays with learners' and teachers' activities. We suggest that the role of the context in constructing physics education can be considered at three levels: micro (individual teacher / classroom), meso (institutional) and macro (supra-institutional, national). At micro level, a teacher constructs learning environments that shape students' learning and the students can actively influence these environments. At institutional level (meso) decisions are taken that shape the curriculum work of individual teachers. Socio-cultural and politico-economical factors at macro level influence all subordinate levels and this level will be the main focus of further discussion. Macro context is also related to national culture.

The individual and the context mutually recreate each other. Each person is not just an observer but also an actor. We assume that context plays an important role in constructing and re-constructing physics education and can provide a frame of reference for the analysis of curriculum values.

RAISING INTEREST FOR CONTEXT IN PHYSICS TEACHING AND LEARNING

Looking at the development of physics education from a historical perspective it is possible to note that discussions about teaching/learning physics before the 1960s were mainly focused on *content* and later shifted to *process* dimensions using a student centred approach. Recently a general agreement has been achieved that the *context* dimension is very important for the design and implementation of the physics curriculum. Currently, physics teachers and researchers experiment broadly with the use of different contexts in the organization of learning activities. For example, physics investigations can be implemented in a variety of outdoor settings such as schoolyards, playgrounds, gardens, and amusement parks (Nilsson, Pendril, Pettersson, 2006). The methodology of physics field experiences in urban environments and "natural" areas is described by Foster (1989) and Popov (2008).

The use of historical contexts and the replication of pioneering experiments in physics can demonstrate genuine methods of scientific discovery (Heering, Osewold, 2007). Arthur Stinner (http://home.cc.umanitoba.ca/~stinner/) from the University of Manitoba in Canada developed a contextual approach to teaching physics called the Large Context Problem (LCP) approach. This approach is based on the assumption that learning could be greatly motivated by a context with one unifying central idea capable of capturing the imagination of the students (Heering, Osewold, 2007). Harvard professor of physics, Eric Mazur and the physics education research group at the University of Minnesota have developed a "rich context problems" approach for collaborative learning. Real world contexts from the students' lives outside school have the potential to generate personal interest in science. A comprehensive overview of research on different methods of using real-life context for improving physics learning has been made by Cahyadi (2007). Researchers from York University (UK) have been working with context-based approaches in science teaching for many years. They found evidence that such approaches motivate pupils in their science lessons and foster more positive attitudes to science (Bennett, Hogarth, Lubben, 2003).

Fencham (2009) discusses the role of the OECD's PISA project for the assessment of scientific literacy among young people for the renewal of interest in context-based science education in different countries. The methodology of the PISA approach was to assess how well 15-year-old students' science knowledge, from whatever source, can be applied to the situations involving science outside school that increasingly confront citizens. The emphasis was on the students' ability to actively use knowledge in new situations. Fencham (2009) talks about 'Context as a Source of Scientific Competence'. The difficulty or ease that students have in answering contextual questions may be due to the context itself (more or less familiar, more or less interesting, more or less relevant) or to the types of questions. However, the PISA project focused only on scientific knowledge and scientific competencies that are pragmatically useful. Sjøberg (2007) argued that this focus neglects other values science has for scientists and for the public such as, for example, creating a sense of wonder about the natural world and the mystery of the universe itself. How this ‘‘sense of wonder’’ can be incorporated into school science curricula remains a challenge.

These works and other recent studies recognise the importance of considering the roles played by the contexts (in micro, meso and macro levels) in constructing and re-constructing physics education, in designing, implementing and achieving physics education curriculum.

CONSIDERING THE CULTURAL CONTEXTS OF EAST AND WEST

Studies of how cultural aspects influence physics education are currently becoming popular, in particular in Asian countries (Pak, 2004). The exploration of the cultural dimensions of the macro context is interesting in this paper as Laos belongs to the Eastern cultural context and Russia officially identifies itself as belonging to the Western cultural context.

According to Jarvis (2009), there are profound learning differences between people from Confucian heritage countries and those from the West. The human brain is social. We are all nurtured in our own national culture. “The culture of a country affects all aspects of the life and thought of the people living there. Like the presence of the atmosphere, it is difficult for people who were born and have grown up in the midst of it to be conscious of. They take everything in their culture for granted; most of them go through their lives without realizing that there can be other ways of living or doing things” (Suzuki, 2001, p. 30).

Jarvis (2009) states that human cognition is not the same everywhere. In the West it is more likely to be individualistic and in the East more communitarian. A major strength of group culture is that individuals are members of a group and are bound by their unity. Within the group individuals are cared for because they are part of the group. The group generates a stronger sense of group solidarity and places more emphasis on the person’s responsibilities to the group or sub-group. However, an emphasis on group culture can be very divisive since each group seeks to create its own boundaries and to protect them against other groups. Considering communication patterns, in- and out of group relationships and social hierarchy are two important dimensions clearly visible when people articulate and express themselves in the presence of other people.

In the West, individualism dominates over group interests. It appears that the individual is more significant than the group. The ideals of Western political and social systems based upon the individual are promoted around the world through mass-media and research communication. Woodrow (2001) talks about ’the imperialism of individualism’.

Western physics education research is often an individual teacher/researcher based enterprise e.g. action research models or design research implemented by an individual teacher in the classroom. Eastern educational research is usually collective work targeting institutional development, rather than the improvement of the work of individual teachers. An illustrative example of Eastern educational research can be “Lessons Studies” in Japan which is the most common form of practical research and capacity building activity in schools. Thus, most educational research publications in Japan are produced by practicing teachers/teams of teachers that present the results of their collective activities (often generated through “Lesson Studies”) oriented towards the improvement of their educational institutions.

Eastern thinking and behaviour is more context and situation sensitive and more clearly related to personal feelings (to the heart). Pak (2004) suggests that traditional Eastern thought is based on connectionism and holism. No individual or unit can exist without connections. “I connect, so I am”. These cultural context characteristics, complemented and validated by our own experiences of living and working in Eastern and Western countries, are summarised in table 1 below.

Table 1 Cultural-context features of learning environment in East and West

East	West
Communitarian	Individualistic
Hierarchical relations within group	Flat organisation of group collaboration
Respect for those who know, for elders, for men, for superiors, strong group loyalty	Freer way of expressing own opinions without age and gender considerations, weak group feeling
Sensitive to ‘loosing face’	Anyone can make mistakes
Unease when working together with strangers	Focus on task not on people, more tolerance for group settings
Detailed discussion to reach consensus, avoiding confrontation	Groups are open for debate, argument and confrontation.

Our experience also confirms data from the literature that gender patterns of behaviour differ between the East and the West. These include spoken and body languages, ways of making eye contact and taking the initiative, expressing opinions and presenting arguments.

The cultural characteristics of learning and behaviour in East and West have certain implications for shared curriculum values in educational systems belonging to corresponding parts of the world. We attempt to present them in table 2 below.

Table 2. Cultural implications for curriculum values in East and West

East	West
Teacher has authority and leadership	Learner has autonomy and self-determination
Focus on ‘bodies of knowledge’	Focus on individual voyages of discovery
Transmission model of teaching	Interactive teaching
Teacher has responsibility for learning outcomes	Learner has responsibility for learning outcomes
High value of the utility of learning	High value of enjoyment in learning
Habits of hard work/studies	Appreciation of combined work & leisure activity
Preference for quiet learning environment & everyone doing the same	Preference for peer-interaction & individual choice

We suggest that it is important to bear in mind these culturally bound characteristics when analysing changes in physics education in countries belonging to different cultural contexts.

THE PURPOSE OF THE STUDY

First, a brief analysis of the recent social changes in Laos and Russia is made based on data collected in and about these countries. Then the study elucidates shifts in societal values faced by the researchers and university physics teachers in the two countries. The analysis explores how these values influence people when they make choices concerning their university studies and professional career opportunities.

The following research questions were formulated

- How do changes in the socio-economic context of an educational system affect the value base of the physics education embedded in this context?
- What are the features of physics education that are most sensitive to changes in the macro-context?

- Are there cultural characteristics that influence physics teachers' and students' academic work?

By elucidating these issues we hope to better understand the challenges faced by physics curriculum actors in the two countries.

METHODS

Working from the perspective that physics education is a socially constructed practice, the research issues raised in this study dictated a need to use a qualitative approach. Qualitative research seeks to understand things in context as socially located and historically developed phenomena (Silverman, 2003). Data was collected through the analysis of literature, conference presentations (in particular, at the Physics in the System of Modern Education conference, in St Petersburg, June 2009) and media sources as well as semi-structured interviews with 3 faculty staff at the National University of Laos (NUOL) and 4 physics educators in Russia. The Google search engine was used for the initial collection of information. Then, data was subsequently screened and controlled through the analysis of original sources of information or compared with data presented on official websites such as the Russian Academy of Science (www.ras.ru), UNESCO and other international organisations.

Convenience sampling technique was used to select interviewees. Authors contacted physics educators they knew from previous academic collaborations. An important selection criterion was that the participants should have more than twenty years of professional experience of teaching and doing research in physics. An interview guide was constructed and pre-tested, focusing on the subjects' experience and opinions about contextual changes affecting the quality of teaching-learning physics at universities from a modern historical perspective. Face-to-face interviews took place in Vientiane, Moscow and St Petersburg in Lao and Russian languages correspondingly. Notes were taken and an mp3 recorder was used to record the conversations during interviews. Before the interviews, all the interviewees were asked for permission to record. The duration of the interviews was on average thirty minutes. Field work and data collection took place during 2009.

The findings were identified and organised in text form without preliminary transcription of the audio-recordings. The texts were shared between both authors and discussed in order to assure the reliable treatment of data.

No separate ethnographic study was conducted as both authors have had experience of doing research and teaching physics at undergraduate level in these countries. Consequently, their autobiographic narratives were used as a source for the triangulation of the findings of the study.

FINDINGS: THE INFLUENCE OF THE CONTEXT ON EDUCATIONAL VALUES AND CHOICES

The case of Russia

When describing the changing situation of physics education in Russia, we need to gain an insight into the soviet socio-cultural context and the historical roots of scientific traditions and successes originating from the soviet time. When people do not have external freedom, as for example in a state system of strict subordination and prescribed behaviour and lifestyle, they seek internal freedom. In the USSR many creative and independent people chose to study physics and mathematics, where there was less interference by the state. The creative freedom of working with physics research was also combined with a high social and economic status. However, many physicists worked hard not for the money, but for personal cognitive satisfaction, social respect and for the benefit their work gave the country.

Well established research schools existed in many universities and academic centres around the country. The biggest research centres also had specialised physics and mathematics boarding schools for gifted children. A system of physics and mathematics Olympics and other competitions were created and a methodology of working with gifted children was developed. Universities had physics and mathematics clubs where students under the guidance of professors worked with children for a couple of days a week. Summer physics camps and physics (technology and astronomy, aero- and radio modelling) circles of non-formal (out-of-school) education existed in every small town.

To create something takes a long time but unfortunately destruction can be very rapid. This is precisely what happened with the science centres and boarding schools after the USSR's self-abolishment; many of them quickly disappeared. Work opportunities for physicists in Russia also shrank dramatically with the dismantlement of the military industry and the closing down of "industrial branch research institutes". So, many thousands of researchers lost their jobs in a very short period of time. Furthermore, the rapid erosion of scientific activities was caused by insufficient state funding, privatisation research infrastructure, emigration and internal migration of scientist to private businesses. The state funding of science has been reduced 20 times since beginning of the 1990s (www.ras.ru).

As a result the number of scientists and male professors in the most productive age of 30-45 years diminished drastically in all academic institutes around the country. One of the interviewees mentioned that currently at Moscow State University (MGU) less than 20% of the professors at the Faculty of Physics (out of 250) are younger than 50 years. The average age of professors in Russia has increased by more than 10 years in the period after the perestroika. Russian physicists and physics educators are aging rapidly. In general, teaching staff in all educational institutions are overrepresented by elderly men and women and in schools mainly by elderly women of about retirement age. This is also understandable as salary level increases according to length of employment. Thus, elderly people are relatively better paid.

When young people choose to study physics they normally aspire to an international career or to work for big private companies within the petrol industry as their dream employment. In the post-soviet period physics studies became popular with an additional specialisation in English. This opened further opportunities for the students to work abroad or to search for employment with foreign companies operating in Russia. Since the early 1990s more than 80,000 of the most dynamic Russian scientists have left the country (Adams, King, 2010), with the total emigration of scientifically skilled labour amounting to over half a million people (BBC, 2002). In the period between 1990 and 2002, the number of people involved in research and other academic activities decreased by 55.2%. In absolute figures, this means that Russian science has lost 1,072,500 skilled people (UNESCO, 2005).

In many branches of physics, scientific productivity is directly related to the amount of time spent in the laboratory. According to one interviewee, in the old days, the main manpower in laboratories was students in their final year and doctoral students. Nowadays, these people spend much of their time outside the research institutions trying to make extra money. Laboratory facilities are also dilapidating. Only the strongest universities have been able to get some state grants to upgrade their material infrastructure in recent years. There is also a significant decrease in the numbers of students applying for physics studies at undergraduate and post-graduate levels. At the same time, over the last fifteen years 3,200 private institutions of higher education and their branches have begun to operate in the Russian Federation along with new branches of existing state universities. Most of them specialise only in the social sciences and humanities and attract significant numbers of young people.

The Russian physicists interviewed suggested that the period after *perestroika* was characterised by a steady destruction of physics education in the country. The system of formal and informal physics education was dismantled on all levels due to a lack of state funding. Currently, major curriculum changes are also being implemented by the government. Astronomy has been taken out of the compulsory school curriculum and is gradually being 'substituted' by the study of religion. The Russian Orthodox Church actively promotes a Bible-based view of the world as an alternative to the materialist worldview. The country is going through the process of active clericalisation and the substitution of the knowledge accumulated by science with faith.

The time allotted for physics studies is being reduced at all school grades. The recent introduction of a national Unified State Examination, known in Russia as *Edinyi Gosudarstvennyi Ekzamen* (EGE) led to changes in teaching methodology. The exam consists of three parts: part A contains multiple-choice questions; part B consists of one-word, fill-in-the-blank questions; and Part C where students are required to write their own solutions to problems or a composition. This exam has a selective character. It is taken by students in grade 9 for admission to high school and in grade 11 for admission to university. It was introduced on an experimental basis from 2001 but since last year it has been implemented all over the Russian Federation. The physics educators interviewed expressed concern that EGE makes teaching in schools oriented not towards understanding but towards passing the exam.

According to the interviewees, additional complications for the survival of physics education in the country were created by the Russian government when it decided to join the Bologna process. Only military and medical universities are exempted from the Bologna model of 3 years Bachelor followed by an additional 2 years Masters education. For all other professions, including physicists and engineers, a two-level system has been introduced and the Masters level will be self-financed by the universities. In practice, this means that it will be accessible only for a small number of students whose parents can afford to pay for studies at Masters' level.

Russian physics teachers and researchers talk proudly about the many bright students that they have had and still have now in their departments. "Sources of talents are inexhaustible in Russia". They narrate stories about their graduates working at different universities abroad or successful businessmen, stock exchange analysts, bankers, owners of construction and other companies in Russia. They emphasised the social importance of developing a physicist's way of thinking: analytical capacity, solid knowledge, schooling in perseverance and problem solving skills that make physics education so valuable per se. However, most of them also expressed bitter feelings that Russian physics education is in worse condition now than twenty years ago, and that they cannot foresee a significant improvement of the situation in the near future.

The case of Laos

Physics and physics education research is currently in a phase of germination in Laos. Research and development projects are run with the help of foreign donors and in collaboration with universities from neighbouring countries and overseas. Four physics lecturers from NUOL are involved in a PhD programme in Sweden (two of them in didactics of physics) and masters' programmes are also being made available, locally and abroad, for new staff.

The university system in Laos was transformed following general socio-economic transformations in the country in the early 1990s. In this period the country faced economic problems as a result of the discontinuation of support from the Soviet Union, a restructuring of the world markets and the process of economic liberalisation. Many foreign investors came to Laos. They opened new businesses that demanded competent local people. This resulted in a rapid brain drain from the university. Some academic staff and in particular good physics lecturers moved to businesses, foreign projects and international donor agencies, or climbed up in the university administration hierarchy thus abandoning practical teaching. Some physics lecturers utilised the new opportunities and went to study in more developed countries in the region and in the West. Thus, the competence of teaching physics in particular its practical-experimental component dramatically decreased during this period.

When discussing the motivation to study physics from a historical perspective, teachers commented on a visible trend of decreasing interest in the study of physics in Laos. Before the 1990s, scholarships were available for all students (higher education was fees-free) and most of the students got a teaching job after graduation. When the students entered into physics studies they had secure work prospects and a clear picture of future opportunities. This picture is rather more diffuse for the students who enter into physics studies today.

Currently, the student selection process to undergraduate physics education in Laos is based on ‘the rest goes there’ principle. After failing national entrance examinations and examinations to the more prestigious faculties such as Economy, Medicine, Law, etc young people take their last chance at the Faculty of Science. If they pass the admission exam to this Faculty they have to choose between different specialisations, i.e. Computer science, Biology, Mathematics, Chemistry, and Physics. The most popular is Computer sciences, followed by Chemistry and Biology, with the last choice for most students being Physics. So, the Physics programme is a kind of ‘last resort’ (least desirable) for the students. Physics attracts almost ten times less students than computer sciences. As an interviewed lecturer commented: *All our students want to study at university but can only get in to Physics. Only 5-10% of them (students at the Physics Department) are interested in studying physics*.

In general, lecturers commented that not many students attempted to study hard. They came to classes without preparation, copied homework from each other, missed classes, etc. At the same time the lecturers did not show much diligence in controlling how students do their studies either. Often, lecturers had extra work in 2-3 places outside the university in order to provide additional income for their families. Private tuition in their subject areas was the most common activity for university teachers. Some staff also engaged in different consultancies and opened small private shops, such as photocopying and digital printing. As a consequence these activities limited the time available for ordinary duties at the department.

Currently, the Laos government has started to make statements about the importance of nurturing talents in the country. A school for gifted children was built up and opened in the capital Vientiane. It is a symbolic gesture marking the political awareness of valuing national scientific capital development. The only PhD in physics at NUOL, the Head of the Physics department, was appointed as a vice-principal of this school. The school specialises in science and mathematics education. The government has promised to provide better salaries, modern experimental and ICT equipment for the teaching staff. The current situation with regard to physics education in Laos is discussed in more detail in the paper by Popov and Vilaythong (2009).

DISCUSSION

In Laos and Russia, the current shifts in the socio-economic context from a socialist to a new capitalist structure with corresponding shifts in values from a collectivist to ego-centric consumerist perspective have influenced the self-interest of individuals. This is reflected in their desire for a quick and stable economic return on their educational investments. Physicists, mainly employed by the state in both countries, cannot count on a high income after graduation. As a result, the context at local and national levels does not stimulate an interest in studying physics as a poor state budget cannot guarantee a decent life for university physics teachers, researchers and physics graduates. To be a physicist is no longer an attractive profession in both countries.

Adams and King (2010) in their analysis of research and collaboration in Russia conclude that the country has been a leader in scientific research and intellectual thinking across Europe and the world for so long that it comes not only as a surprise but also as a shock to see that it now has a small and dwindling share of world activity as well as real attrition of its core strengths, notably in physics and space science. The problems faced by people in the pure physics research field are even more acute in the field of physics education. For example, laboratory equipment in schools and universities has not been upgraded for decades. State production of such equipment became privatised, prices for locally produced physics instruments soared, so consequently not many consumers can afford it. Thus physics education is becoming less laboratory focussed. The practical component in education suffers first when unfavourable changes for science development take place in a national context.

Russian professors have one of the lowest salary levels in the world, comparable only with some poor African and Asian countries such as Laos. Old professors are trying to maintain traditions of high quality in teaching but they experience less support from younger assistants and notice a significant lowering of students' knowledge as admission criteria for physics studies are dropping.

The proliferation of private higher education institutions becomes a problem in many countries around the world as the expansion of the student population leads to a lowering of educational standards. This has also become the case in Russia and Laos. "It can be argued that the enormous number of newly created universities and other institutions of higher learning represent a loss for Russian science and academia." (UNESCO, 2005, p. 139).

Physics education in Laos has changed less than in Russia, as the initial situation was very different. Using the words of the French philosopher Jean Baudrillard (1929–2007), it is possible to talk about 'simulated physics education' in Laos, when teachers pretend that they teach physics and students pretend that they learn. In this way physics students can obtain a diploma of higher education that opens employment opportunities for them in fields others than physics.

The Russian situation exemplifies how the macro level contextual changes have led to a shift from collectivist to individualist values in society and educational system. According to Feigel'man (2007), society has been atomised into a collection of weakly interacting individuals. This can also be interpreted as general shift from an Eastern to a Western ideology of education. The new generation of Russian educational researchers and administrators eagerly adopt Western fashionable theories and approaches neglecting scholarly traditions developed by generations of talented physics educators in the country. A corresponding shift in teachers' priorities is also visible through the exclusion of more resource-demanding and time consuming components from the physics curriculum and the transfer of responsibility for the outcome of studies to the students. An individualist approach and the principle of the survival of the fittest have become dominant in the educational system.

The individual and the context mutually recreate each other. The context is not just the surrounding environment observed by an individual but it is also created by him. Each person is not just observer but also an actor. However, as one of the Russian interviewees commented, Russian society is developing a habit of living without science. The past achievements of soviet science tend to be forgotten by the general population and even unknown for younger generations. Modern scientists do not represent 'professional and human models' for Russian youth, as they do not see the scientist as a respected profession in society. A materialist approach and scientific worldviews tend to be presented in the media as archaic and belonging to the communist past. Societal values are changing with changes in the macro-contexts and this affects the status, functioning and prospects of science and science education in the country. In conclusion, we can say that in spite of different points of departure it is possible to trace similar trends in the development of physics education in Russia and Laos that are caused by similar contextual changes.

ABSTRACT

This study explored the relationship between preservice science and mathematics teachers' subject matter knowledge, pedagogy, and pedagogical content knowledge through the lens of reflective practice. Three preservice teachers participated in the study. Two course instructors (mathematics and science) used microteaching experiences during a method's course as a context to explore how the concurrent development of pedagogical skill, pedagogical content knowledge and subject matter knowledge were influenced by reflective practice (Schön, 1983). Self-reflection questionnaires, videos of microteaching and lesson plans were each used to develop a case study of each participant. Suggestions for future research are also discussed.

Keywords: *Pedagogical content knowledge (PCK), pedagogy, reflective practice, science teacher education, mathematics teacher education.*

INTRODUCTION

According to the Professional Standards for Teaching Mathematics (National Council of Teachers of Mathematics, 1991) one of the crucial factors in teachers' professional growth is the extent to which they "reflect on learning and teaching individually and with colleagues". We agree with this position and believe that it is important to provide preservice teachers with opportunities to reflect on their own teaching. There is a significant body of work that supports the value of teacher reflection but the following study is unique among them for the lens that is used, content knowledge.

This study is the first in an ongoing exploration into the relationship between pedagogical content knowledge (PCK), pedagogical knowledge (PK), content knowledge (CK) (Shulman, 1986) and the reflective practice (Schön, 1983) of preservice teachers. Ultimately, this paper characterizes the PCK, pedagogical understandings and reflective practice of preservice mathematics and science teachers given differences in content knowledge. The current aim, therefore, is to describe the similarities and differences in their reflection on and enactment of feedback related to these domains of teacher knowledge. The following questions guided this study: How do reflections influence changes in teaching practice among teachers with varying degrees of content knowledge? And, what is the nature of the changes that take place?

BACKGROUND

Three preservice science and mathematics teachers, Oscar, Yvonne, and Erica are described in this study. Each of them completed both microteaching and reflection questionnaires as coursework during an introductory methods course. Microteaching is practice for preservice teachers to design and implement a lesson with their peers acting as a “class”. The methods course was embedded within a combined masters degree and secondary certification program at a private, midwestern university and was designed for the simultaneous inclusion of both mathematics and science teachers.

At least two days prior to each lesson, the preservice teachers submitted a detailed lesson plan to both course instructors. The lesson plan included objectives, activities and assessments as well as a detailed script of possible student questions that may arise during implementation along with potential responses. Following the implementation of the lesson, each teacher shared their impressions of the strengths of the lesson as well as their impressions of the difficulties students might encounter if participating. Both course instructors then shared pedagogical and content specific comments and concerns. The lesson was video-recorded and a copy was given to each teacher. They were asked to watch their lesson at home during the following week and to respond to a questionnaire eliciting their perceptions of the strengths and weaknesses of their design, delivery and facilitation of any activities. In particular, they were asked to respond to following questions:

1. Please describe three things that went well during your lesson and explain why?
2. Please describe three things that did not go well and explain why?
3. If you could teach this lesson again what you would do differently? Explain why.

The questionnaire was open-ended and the preservice teachers were asked to be as detailed in their responses as possible.

METHODOLOGY

Using the theoretical framework, both authors separately developed a description of the evidence in microteaching of the teachers’ content knowledge, pedagogical content knowledge, pedagogical skill, and reflective practice. Description of the subsequent lesson was developed similarly but was also scrutinized in light of the feedback and self-reflection from the previous lesson. This facilitated an exploration of the enactment of their reflections and instructor feedback. Essentially, did they make changes to a later lesson given the experiences in the previous lesson? This allowed for a characterization of each teacher’s reflective practice to begin to emerge. The authors then developed a single case study of each teacher through repeated discussions of their individual descriptions and impressions. The analysis specifically included incidences of content errors, the teacher’s general comfort level with certain topics, evidence of consideration for learners, evidence of growth in a subsequent lesson, group discussion and their self-reflection.

Participants

The preservice science and mathematics teachers, Oscar, Yvonne, and Erica were selected because they were representative of a spectrum of content knowledge determined by the mathematics and science courses in their undergraduate degree programs, self-report, and instructor observations made during science and mathematics content activities embedded within the methods class. These activities will be described in greater detail in the analysis section. Yvonne, a mathematics preservice teacher, entered the program exceptionally confident about her content knowledge. Although she did not have experiences in classroom settings, she had tutored several family members in middle grades mathematics and was familiar, as a parent, with secondary mathematics curricula. At the time of the methods course she was dedicated, full time, as a stay at home mother. Her previous positions were each in technical fields that involved mathematics including statistical methods and accounting procedures.

The other mathematics preservice teacher, Erica, had low self-efficacy as evidenced anecdotally through her verbalizations about her discomfort with her subject matter knowledge. She was also pursuing certification as a second career and had experience in previous positions with accounting. Although her content knowledge was not as developed as the other preservice teacher, she was employed as a substitute teacher and teacher's aide. Little of her reflection centered on her experiences in the classroom, however.

The third participating teacher, Oscar, was enrolled in the same program as Erica and Yvonne but by contrast had a more sophisticated understanding of both his subject matter and pedagogy. He was the youngest of the three participants and had graduated from university two years prior to the study. Within his undergraduate program he had the opportunity to work as a research assistant in a research lab and hoped to be able to bring more non-traditional, reforms-based content (i.e. nature of science and scientific inquiry) into his classroom.

Analysis

Several mathematics and science content activities were embedded within the course as models of lesson strategies. The preservice teachers reactions to these lessons further illustrated the differences in content knowledge and content-specific self-efficacy of each of them. One mathematics lesson, in particular, demonstrated the stark contrast between Yvonne and Erica. This lesson was designed to allow participants to visualize operations with fractions using tiles without depending exclusively on the algorithm for a solution. While Yvonne worked through each of the problems successfully and with enthusiasm, Erica became increasingly frustrated and struggled with the visualization of the multiplication and division of fractions. After the activity, Erica became very emotional and described her frustration with "material she thought she understood". This activity took place early in the semester and was the first of many instances when she voiced concerns with her content knowledge.

The teachers' first encounter with lesson planning and teaching was content neutral. During an early class session, they were asked to write a lesson plan on the topic "Tying a shoe", and then teach it to their peers. The instructors provided a model of a shoe and laces. The difference in their knowledge of learners and pedagogy began to emerge during this activity. Yvonne used a model of a shoe to show students five times how to tie a shoe, and then she asked them to repeat the process, never showing students the rationale for the lesson. In contrast, both Oscar and Erica introduced the activity by showing students why it is important to learn how to tie a shoe. Oscar entered the room with his shoes untied tripping to initiate the discussion of the importance of having shoes tied. Erica simply asked what would happen if their shoes were untied to elicit students ideas. This initial activity illustrated that they fall on a spectrum of knowledge about learners and pedagogy. The following paragraphs provide more details about each teacher.

Yvonne

Yvonne's first lesson exemplified her confidence in her mathematical knowledge in contrast with the second mathematics teacher, Erica. The lesson was written for a second year algebra class and focused on solving systems of equations graphically. The content of the lesson was both accurate and appropriate for the secondary classroom she developed the instruction for. Understandably, the pedagogical sophistication of its implementation was lacking and while this is not concerning particularly given that this was the first teaching experience for Yvonne, her reflection on the experience did not suggest a consciousness of the growth needed for effective teaching. More typical teaching concerns such as the appropriate use of wait time before accepting student responses to teacher's questions and having limited movement around the classroom or interactions with students were evident. More subtle, though equally common, instances of lacking pedagogical content knowledge were also an issue. For example, although it is possible (and pedagogically acceptable) for a student to graph a line *without* first putting it in the $y=mx + b$ format, Yvonne required that students make this change prior to graphing. She was confident with this material; however, she was not flexible with the graphing of all forms of the equations. Consequently, she was unable to teach this content in a variety of ways.

Her reflection on the lesson itself, after viewing the video of her experience, essentially lacked any reflection at all. In particular, she noted one strength of her teaching episode, “I felt prepared”; and a few weaknesses, “assessing students’ understanding, missed teaching opportunities, and facing the board when writing.” Nevertheless, she did not use this information to describe what changes she would make if she could teach it again, which was a part of the reflection assignment. The only substantive statement, “I felt like the time got away from me, and I was not able to give a concise summary” did acknowledge the lack of closure to the lesson as pointed out to her by the instructors during the debriefing session after the lesson, as well as on their written feedback.

The following lesson did include this much-needed component of lesson planning and implementation. However, this was the only aspect of planning and instruction that improved between the first and second lesson. In her reflection to the second teaching episode she outlined the same strength, “I felt really good about the topic”, and weaknesses, “assessing students’ understanding, missed some learning (maybe teaching) opportunities, and still facing the board, but less this time.” This further illustrated her confidence in her mathematical knowledge, but also the lack of understanding of the importance of revisiting ones own understanding in order to become effective teacher.

Erica

Erica consistently voiced concerns about her content knowledge and was apprehensive about her preparation for mathematics teaching from this perspective. In contrast, her experiences as a substitute teacher and teacher’s aide gave her insight into the realities of teaching and the needs of students that the other preservice teachers did not have. The content of her lessons included in the analysis was accurate and appropriate for the middle grades mathematics classroom she was preparing for. Her first lesson was an introduction to the use of a protractor. The introduction to the lesson, in which students created paper airplanes, as well as her extensive use of questioning evidenced Erica’s knowledge of students. Within her reflection on the lesson, her acknowledgment of her own strengths and weaknesses were consistent with the instructors’ perceptions including those that were not explicitly shared with her during the debrief of the lesson’s implementation. Even within the pedagogical concerns she identified there was a consistent and overarching concern with her subject matter knowledge.

> *I used a lot of “ums” and “so” and I need to make a conscious effort not to do that in class. It begins to take away from the lesson and possibly give an impression of not being confidant or knowing the material.*

The lesson that followed was intended to provoke discussion of how mathematics is used as a selling tool within advertisements. Although this lesson did not go as smoothly as Erica intended, there were distinct and noticeable improvements made over her first lesson. For example, her use of questioning in both lessons was extensive but there were several instances in the first teaching session in which she did not wait before providing an answer or moving on to another student. This lack of wait time was a concern and was discussed during the debriefing session that followed. Her subsequent lesson showed observable improvements in this regard and she pointed out in her reflection that she had “good time left between questions from the teachers to students to allow them to respond to questions asked". A linear relationship between the two cannot be argued here due to the limited scope of the data analyzed, however, growth between teaching episodes was evident. Furthermore, Erica made explicit references within her reflection on her first teaching experience regarding both positive and negative teaching moments and pedagogical choices that were then corrected in the next lesson. Although her mathematical knowledge was less developed than Yvonne, she was considerably more reflective about the instructional content and demonstrated more significant growth between lessons.

Oscar

In contrast with the other two participants, Oscar had both a sophisticated understanding of his content relative to the secondary biology curriculum, and also demonstrated pedagogical thoughtfulness that is generally uncharacteristic of preservice teachers. Analysis of his teaching and lesson planning before and after reflection demonstrated the nature and influence of Oscar's reflective practice. The first lesson he implemented for the methods course focused on mutations in DNA sequences. The content of the lesson was accurate and appropriate for the intended audience and there were also instances within the lesson design that demonstrated Oscar's awareness of and attention to student misconceptions and beliefs. For example, he began the lesson with a picture of cartoon characters that the students were familiar with and used them as a platform to draw out their conceptions of the nature and implications of mutations within individuals. Although this was Oscar's first teaching experience, evidence of developing pedagogical content knowledge also emerged within the analysis of his teaching and lesson planning. Within this first lesson, he effectively developed and used analogies to present unfamiliar ideas.

Oscar did have some difficulties, however, with effectively working through the misconceptions he was able to draw out. Within his reflection on his lesson he discussed in detail his own frustrations with his inability to effectively describe the phenomena he intended to. Oscar's reflection on the first lesson went beyond the specific focus points of the post instruction debrief and he included concerns about the experience that were not noted by either instructor or his peers.

> *When we were talking about mutations that could be beneficial for a lion we named a few and I explained how these traits are passed down and how lions would become faster and faster. Then later in the discussion Yvonne asked about traits and heredity in terms of her brother and I then said that those aren't passed on. So I contradicted myself and may have confused the students and created a misconception that traits are not passed on from generation to generation.*

Instances such as this one illustrate two things about Oscar when compared to the other two participants. The first is that Oscar's weaknesses lay, understandably, within his knowledge of learners. A weakness most notably improved through experience, which he did not yet have. The second is that he was much more reflective about his practice than Yvonne with an equally sophisticated understanding of content. More importantly, the impact of this reflection was observable in the following teaching experience.

Oscar focused the second lesson on meiosis and specifically on providing students with an experience to help them to understand and remember at which stage of meiosis crossing over occurs. Although the lesson had some logistical concerns, there was a distinct and noticeable improvement in his attempts to use questioning to draw out misconceptions and to reinforce understanding. Additionally, while the previous lesson had a teacher-centered conclusion in which Oscar essentially restated the definition of a mutation and reiterated diseases attributable to them, closure of the second lesson was student centered and consisted of Oscar posing questions to the students and using their responses as a review of the material just discussed.

Conclusions and Implications

The three profiles just described are representative of a continuum of teacher knowledge and reflection and are illustrated in the figure below.

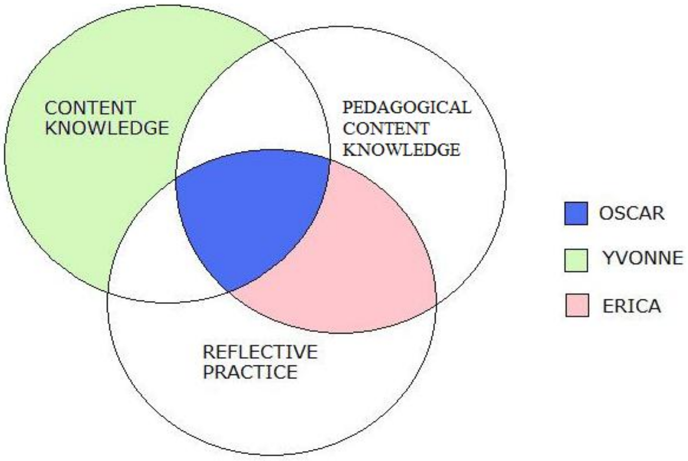

Figure 1: Teachers' profiles

Yvonne, represented a typical preservice teacher. She had sufficient content knowledge, but had no knowledge of pedagogy and students. Quite the opposite was Erica, a mathematics preservice teacher who consistently expressed concern regarding her content knowledge, but showed knowledge of pedagogy and students that is not expected of someone just beginning a certification program. Lastly, Oscar, a science preservice teacher, demonstrated sufficient content knowledge as well as knowledge of pedagogy and students. The differences among these three preservice teachers were obvious after their first teaching session. However, in this study we were interested to see if the difference in content knowledge affects how preservice teachers reflect on their microteaching experience, and how this reflection influences future practice. Although the assertions that can be made here are limited, given the scope, the case studies developed ultimately suggest that content knowledge is not a determining factor in the development of pedagogical knowledge. The critical factor in the transition between content knowledge and the development of pedagogical content knowledge is reflection.

While Schön (1983) emphasized the distinctions between reflection-on-practice and reflection-in-practice, and both are of critical importance, this study limited itself to preservice teachers' reflection *on* their practice. Even among experienced inservice teachers influencing changes of reflection in action is problematic (Derry, Wilsman, & Hackbarth, 2007). This study, furthermore, does not aim to describe a means for facilitating change in teacher practice but is instead a characterization of the relationship between content knowledge, PCK development, and reflection.

The implications for this study include changes in the way feedback is provided to preservice teachers such as the participants in this case. Given the concern with the development of pedagogical content knowledge, incorporating content specific prompts intended to elicit their thoughts about what subject content *is* specific to teaching should be included when possible. Also, preservice teachers should be asked to explain how PCK-related feedback impacted subsequent lessons or lesson planning in addition to particular aspects of their common content knowledge and pedagogy.

The development of PCK is not automatic and mathematics and science teacher educators routinely provide feedback to encourage growth in both pedagogical skill and, when possible, content knowledge. This study illuminates current understanding of the potential relationship between content knowledge and the development of pedagogical content knowledge and the role of reflection as a mediator between the two.

ABSTRACT

Recent studies have highlighted the need for better integration of Education for Sustainability (EfS) into pre-service teacher education in Australian universities. This case study explores some of the issues surrounding this imperative in one institution, with particular emphasis on the Science and Technology Key Learning Area in Primary teacher education. It found that key concepts within ecological sustainability were thoroughly covered in the Science and Technology units, that, although some efforts were made to link these to broader issues of political and social sustainability, this was constrained by a number of systemic barriers, and that issues of economic sustainability were scarcely visible across the degree program. The study highlighted the difficulties of addressing EfS in a holistic way within tightly circumscribed science and technology units, and that improved, explicit communication structures were essential to facilitate conceptual links between EfS concepts within the Science and technology area, and between Science and Technology and other Key learning Areas within Primary Education awards.

INTRODUCTION

The need for effective Education for Sustainability (EfS) in school-based education is now compelling, as the planet faces significant environmental challenges of which global warming is the most high profile. EfS should encourage students to become more socially critical and begin questioning their own and societal behaviors with respect to environmental impact. Accordingly, EfS is commonly perceived as a cross-disciplinary endeavour: an underlying perspective or referent that should inform and permeate all aspects of students' school experience. Australia, a country beset by environmental problems associated with human activity such as land clearing and a major contributor to carbon dioxide emissions, has taken these challenges on board to some extent. Strong EfS policy statements have been produced at both federal and state levels (Commonwealth of Australia DEH, 2005; Australian Government, Department of Environment, Heritage and the Arts, 2009), along with the Australian Sustainable Schools (AuSSI) initiative and many excellent examples of whole-school, action-oriented initiatives connecting community, curriculum and the management of school resources and grounds (Australian Government, Department of Environment, Heritage and the Arts, 2005). However, the uptake of these policies and initiatives is very patchy, and strongly dependent on individual champions of the cause in schools. In addition, many shortcomings in the teaching of EfS reviewed by Tilbury, Coleman and Garlick (2005) persist at both the primary and secondary levels.

Some authors (e.g. Cross, 1998; Taylor, Nathan & Coll, 2003) reported that both primary and secondary teachers, even those with a particular interest in the environment and sustainability issues, had limited understanding of the concept of sustainable development or sustainability goals. Furthermore, Walker (1995) argued that teachers considered that EfS requires specialist knowledge and this perception inhibited their efforts in this area. As an example, teachers may lack knowledge of EfS pedagogy including the skills of integrated planning. Certainly there are many studies indicating that teachers do not hold the knowledge and understanding that is deemed necessary for implementing EfS. These include reports that teachers may lack understanding of the fundamental ideas and practical procedures underpinning EfS (Robertson & Krugly-Smolska, 1997; Skamp & Bergmann, 2001; Summers, Corney & Childs, 2003; Taylor, Nathan & Coll, 2003; Kennelly, Taylor & Jenkins, 2008; Skamp, 2009). There are also reports that teachers may lack understanding of environmental concepts (Summers et al., 2000; Khalid, 2001; Cutter-Mackenzie & Smith, 2003; Flogaitis, 2003; Summers, Corney & Childs, 2004, 2005; Parlo & Butler, 2007; Skamp, 2009). As an example, Skamp (2009: 103) concluded that:

> Content knowledge is a prerequisite to pedagogical content knowledge. Teachers will not engage students in a wide variety of environmental … activities if they are unaware of the environmental knowledge associated with the cognitive outcomes from those activities… Awareness of general and abstract environmental knowledge may not be sufficient…Explicit professional development workshops focusing, in part, on specific content knowledge … might address this issue.

A consequence of this limited understanding of EfS is that teachers lack confidence in their ability to question and change prevailing conditions in their schools. Jenkins (1999/2000) reported feelings of disillusionment and disempowerment amongst pre-service teachers, because the responsibility of teaching EfS was too great and they believed they could not make a difference. Teachers have also expressed a strong need for the support of their principal and colleagues for their EfS efforts (Kennelly, Taylor & Jenkins, 2008). A lack of confidence can only be expected, in an educational endeavour, which has been described as ‘transformative’ and which in many practical ways challenges everyday expectations and routines of school.

The inference is that the pedagogy of EfS and the social and ecological understanding deemed necessary may have been missing from teacher preparation, or where they have been included, they may not been offered in such a way as to allow, or to motivate teachers to make connections between human practices, ecological understanding and their relevance to teachers’ everyday professional work. This is very unfortunate, as, according to Said, Ahmadun, Paim and Masud (2003), teachers are potentially instrumental factors in the formation of students’ attitudes about the environment. Furthermore, research by Miles, Harrison and Cutter-Mackenzie (2006) with pre-service teachers in Australia, indicated that in general these teachers were keen to draw on EfS in their future teaching. However, this research also confirmed that many of these teachers felt their levels of preparedness and confidence were low and their knowledge inadequate.

Many of these issues suggest that teachers, both primary and secondary, are inadequately prepared in the area of EfS, and certainly based upon their findings in the Australian context, Miles et al. (2006: 57) concluded that:

> Despite national and international policy rhetoric about the importance of pre-service teacher preparation in environmental education … there are still inadequate levels of environmental education provision at the teacher education level and that pre-service teachers’ preparedness for teaching environmental education is overwhelmingly low.

Other authors have made similar claims about EfS in teacher education in Australia. According to Tilbury, Coleman and Garlick (2005), there has been a dearth of EfS in teacher education programmes and this has resulted in a lack of competence amongst teachers to effectively teach EfS in schools. Similarly, Cutter-Mackenzie and Smith (2003) argue that it is the lack of pre-service and in-service teacher training in EfS that poses one major barrier preventing or limiting the effective implementation of EfS in primary schools. These and other authors (e.g., Ferreira, Ryan and Tilbury (2007), Fien and Tilbury (1996), Tilbury, Coleman and Garlick (2005) have signposted the need to integrate education for sustainability (EfS) into pre-service teacher education programs.

Several examples of integrating EfS into teacher training courses are emerging. Recent projects emanating from The Australian Research Institute in Education for Sustainability (ARIES) have strongly promoted and facilitated integration of EfS into teacher training programs at several Australian universities. One of these projects was the catalyst for the research reported here. Paige, Lloyd and Chartres (2008) have reported a transdisciplinary approach to integrating EfS into primary teacher education where science, mathematics and ecologically-related aspects of society and environment and are taught in an integrated way based on clearly articulated rationale of educating for ecological sustainability. The challenges and opportunities of online teaching of environmental education pre-service teacher education have been discussed by Whitehouse (2008).

The Australian draft National Curriculum (Australian Curriculum Assessment and Reporting Authority (ACARA), 2010) has potential for incorporating EfS more comprehensively than some existing State curricula, with “Commitment to Living Sustainably” as one of three cross curricular themes which is explicitly mapped throughout the curriculum strands. Sustainability is also referred to in aspects of History, for example, referring to ‘concern for the environment’, while science has a number of aspects that refer to the applications of science to society and the world, including, for example, ‘an ability to solve problems and make informed evidence-based decisions about current and future applications of science, while taking into account moral, ethical and social implications’.

The research reported here examines issues related to integrating EfS within the Primary Education awards currently being offered at one of Australia’s oldest and well-known teacher education institutions. The study focuses on the Science and Technology Key Learning Area in primary teacher education, and is embedded within an action research framework. It is one of a sequence of iterative cycles of action and reflection that has informed the integration of EfS in the Science and Technology key learning area of pre-service primary teacher education at our institution. It builds upon and is informed by preceding studies relating to our local teaching and learning context (Taylor, Kennelly, Jenkins, & Callingham, 2006; Kennelly & Taylor, 2007). It also draws upon subsequent broader, collaborative, cross-curricular activities such as editing a book specifically targeted at primary school educators (Littledyke, Taylor, & Eames, 2009) and participation in a cross-institutional project aimed at mainstreaming EfS into pre-service teacher education (Littledyke et al., 2009). By reflecting and acting upon our local context as simultaneously investigators and participants within an action research framework, we aim to enhance the ability of our graduates to integrate EfS into the Science and Technology key learning area at primary schools.

RESEARCH CONTEXT

This study, which is part of a broader, cross-institutional project, focuses on six units that are offered in various primary education pathways at a rural Australian university with a long history in teacher education.

The six units at the focus of this study contribute to the science component of awards, which are structured along traditional disciplinary boundaries reflecting the key learning areas in school syllabus documents. Two of the units are core 2nd year units for students studying a Bachelor of Education (Primary): one of these is face-to-face and the other unit is by distance, with a five-day face-to-face intensive school on campus. A further unit is a core 4th year unit called "Primary Environmental Science for Sustainability". This unit has a dual focus: to build on the scientific content knowledge of the 2nd year science and technology units, and to better integrate EfS into the primary teaching degree. Its development was founded on strong theoretical underpinnings and from a philosophy consistent with holistic, integrated practice (see Kennelly & Taylor, 2007), with a thematic approach emphasising action-competence and experiential learning, including field trips ranging from a sewerage treatment plant to a World Heritage National Park. The remaining three units are electives with much smaller enrolments, taken by students taking other degree pathways, for example, combined General Studies/Teaching degrees. All of these units are the responsibility of three unit co-coordinators who were participants in this research.

The national context at the time of the study included imminent release of a new National Curriculum (now released in draft form), and the recent adoption of National Assessment in Literacy and Numeracy, results of which may be linked to school funding. A national joint initiative called 'Primary Connections', between the Federal department responsible for education and the Australian Academy of Science, is developing and disseminating high quality curriculum resources explicitly linking science with literacy outcomes.

METHODS AND DATA COLLECTION PROCEDURES

The study was conducted using a mixed-methods approach. Data collection for the broader project comprised two online surveys and a semi-structured interview with key teaching staff across the whole School of Education, including the Science and Technology team whose responses form the basis of this study.

In the first online survey, the concept of EfS was explicitly articulated according to the four themes of ecological, social, economic and political sustainability, following Commonwealth of Australia DEH (2005). These survey items asked participants to indicate whether their units explicitly addressed key concepts identified by Commonwealth of Australia DEH (2005), and shown in Table 1, within each of the four sustainability themes.

Table 15: Key concepts within the four dimensions of sustainability (source: Commonwealth of Australia 2005, p. 17)

Ecological sustainability	Social sustainability	Economic sustainability	Political sustainability
Biodiversity	basic human needs	Cost-benefit analysis	citizenship
Habitat	cultural diversity	Economic development	democracy
Carrying capacity	cultural heritage	Eco-efficiency	decision-making
Conservation	human rights	Life-cycle analysis	tolerance
Ecological footprint	intergenerational equity	Natural capital	power
Ecology	participation	Natural resource accounting	respect
Ecospace	peace	Steady-state economy	conflict resolution
Ecosystems	risk management	Sustainable consumption	
Interspecies equity	social justice	Sustainable production	
Natural cycles and systems		Triple-bottom line	

In order to map the integration of EfS concepts in the formal curricula of the units at a reasonably fine scale, this survey asked participants to indicate whether or not each of the concepts shown in Table 1 were explicitly addressed within the following aspects of the units: title, synopsis, lecture topics, readings, tutorial/workshop activities, web resources, summative assessments and/or learning outcomes.

The second online survey focussed on unit coordinators' perceptions of sustainability and EfS, and the perceived barriers and opportunities to incorporate EfS into their units and more broadly into the School of Education. Participants provided responses to survey items, which also included open-ended questions about their perceptions of EfS and their teaching practices. Likert scale questions relating to perceived importance of aspects of EfS were rated on a 5-point scale from Very Low to Very High, while questions relating to the extent of EfS inclusion were rated from Very Little to Very High. Surveys were administered using the SurveyMonkey software and filled in individually without consultation with other team members.

Interviews probed more deeply into individuals' perceptions of EfS, with particular emphasis on barriers, opportunities and required actions. Interviews were structured to some extent by questions focusing on themes of interest, followed standard protocols relating to ethics and confidentiality, and were audio taped.

In order to summarise the profile of EfS across the units, a profile index was calculated for each of the dimensions of ecological, social, economic and political sustainability. This is the total number of times that the individual concepts within each dimension occurred in the different aspects of the six units. Responses from the science and technology staff were collated to provide a picture of the individual and collective perspectives underlying the teaching in the Science and Technology units. Illustrative quotations are taken from the survey responses to provide richer account of the views of the staff.

RESULTS

PROFILE OF EFS WITHIN SCIENCE AND TECHNOLOGY UNITS

The profile of the four dimensions of EfS across the units, as indicated by the profile index, is shown in Figure 1.

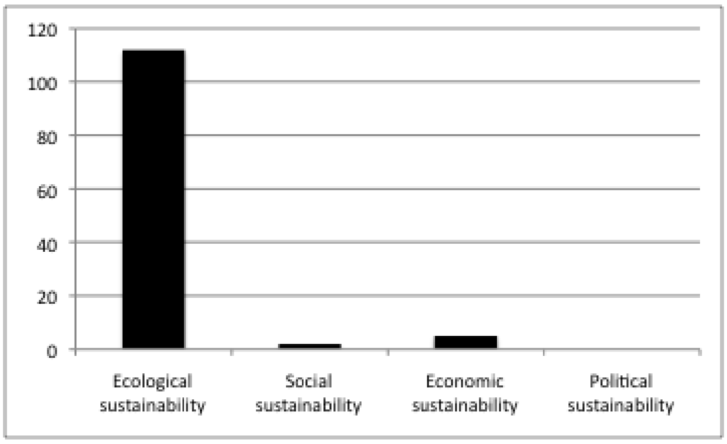

Figure 4: Profile of the four dimensions of Education for Sustainability across six Science and Technology-related units.

As shown in Figure 1, while ecological sustainability was covered extensively within Science and Technology units taken by pre-service primary education students, the other three dimensions of sustainability were mainly invisible. None of the concepts central to political sustainability were reported as being explicitly addressed in any of the units. Within the dimension of social sustainability, only the concept of risk management was addressed in part of one of the units. Within economic sustainability, only the concepts of sustainable consumption and production were addressed.

The more detailed picture of the coverage of concepts within ecological sustainability across the six units, using the same indexing procedure as above, is shown in Figure 2.

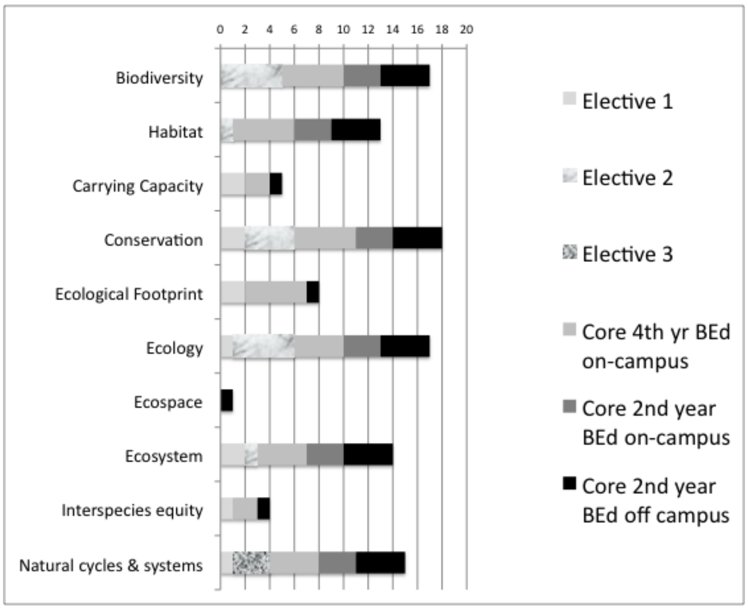

Figure 5: Concepts of ecological sustainability addressed in Science and technology units taken by primary education students

As indicated by Figure 2, the core units explicitly cover most of the key concepts, with the exception of the idea of ecospace, which is addressed only in one of the core units. Overall, the concepts of conservation, biodiversity, ecology, natural cycles and systems and ecology were respectively the best represented. These concepts are also the most narrowly 'scientific', in the sense that they do not subsume to any significant extent concepts of equity and resource use that are such important components of the ideas of ecospace, interspecies equity, carrying capacity and ecological footprint, which were much less represented.

PERSPECTIVES OF SCIENCE AND TECHNOLOGY TEACHING STAFF

Many common views were apparent among the self-reported perspectives of the four staff members associated with the Science and Technology unit. All rated the importance of EfS generally as Very High.

- Teachers must be well prepared to teach EfS because of the seriousness of global problems of sustainability
- If they [the pre-service teachers] don't go out there prepared to take action and prepared to sort of think critically about what they are hearing, or what they use, or what they doing, then you know, it's not going to get any better.

All rated the importance of EfS in the Science and Technology teaching area as High or Very High:

- Many EfS concepts link to science concepts - also I feel that good EfS should be underpinned by a good understanding of science concepts.

Similarly, all the staff rated tacit matters such as their own values, attitudes and practices in EfS as High or Very High.

- It is important for me as a lecturer to covey the types of values etc that I hope my students will adopt
- I think you've got to provide a model of good practice yourself, in how you talk about the environment, in how you deal with the environment… if you're actually behaving in a way that's contrary to what you're teaching then I don't think that's good.

All the participants rated as Very High the importance of EfS being addressed systematically across curriculum areas of teacher education programs in the School of Education. A number of barriers to this imperative, spanning a range of several externally imposed constraints and internal practices, were also highlighted.

Arguably one of the most intractable externally imposed perceived barriers related to the narrowly circumscribed requirements mandated by one of the professional accreditation organisations. The narrow and specific unit outcomes adopted in compliance with accreditation requirements flowed on, via the logic of 'constructive alignment' (Biggs, 1999) to many other aspects of the units including the activities and assessments. For example, in part as a consequence of accreditation processes, the 'Primary Environmental Science for Sustainability' unit originally designed to provide a rich experiential and action-oriented learning environment was slightly reoriented via assessment changes in a way that runs theoretically counter to these ideals of EfS. Comments relating to this particular barrier to integrating EfS into the Science and Technology stream included:

- Demands of DET [Department of Education and Training] and NSWIT [New South Wales Institute of Teachers] emphasise state standards and curriculum, which has low priority for EfS

- The need to cover a range of science concepts in more breadth/depth, and NSWIT requirements that closely define the outcomes that I can address in one science/sustainability unit

- Professional accreditation constraints and demands coupled with narrowly circumscribed disciplinary areas in the course structures

Other issues of concern raised by some of the Science and Technology staff included a perceived lack of scientific background among the students, and perceived irrelevance of EfS to staff and students:

- Quite a number of those students were really interested in sustainability but had not the slightest clue about how to go about teaching the fundamentals from an environmental perspective or from a scientific perspective, they simply had not the scientific ground to do so.

- Perceived irrelevance (by staff and students) of EfS to individual teaching areas.

An internal issue raised included a lack of integration and communication between disciplinary areas in the primary awards:

- Silo mentality of tutors in units and teaching areas creating major barrier to integration

- EFS is really, in my view of it, it's a holistic, cross-cultural, multi- perspective type of thing and we can teach it from a science perspective … but the breaking down of a curriculum into these little units for us and for the school kids is one barrier, the other is that we need more integration and communication of what is in the individual units.

Discussions of the barriers to integration of EfS also highlighted concomitant possibilities to enhance integration. The major mechanism to further enable EfS raised was improved communication:

- I would like to see much more vertical integration and communication of what is in the different units in the awards.

- Cross-discipline team discussions and plans for sequencing and incorporating aspects of EfS semester by semester, year by year across courses

In general, the second survey and follow-up interviews indicated that our team and associated staff were highly committed to principles of sustainability, both in our personal lives and professional roles, and within the science units attended to tacit issues and positive role modelling in teaching practices. We shared strong concerns about the impact of accreditation processes on integrating EfS into and beyond the Science and Technology discipline, and saw improved communication and integration between staff across different disciplinary areas as a necessary and crucial enabler of better integration of EfS.

DISCUSSION

In discussing these results, the first point to be made is that we view the reflective processes involved in participating in the study itself, as an extremely useful professional experience, which has inspired our continual involvement in this endeavour and prompted us to consider ways of refining our praxis. This collaborative process is consistent both with principles of action research models (Kemmis and McTaggert 2005) and the broader ideals of sustainability.

It is apparent from the results that even though interconnectedness is theoretically more tractable in primary education systems (Littledyke, Taylor & Eames 2009), and despite committed key staff working from a holistic philosophy over several years, integration of EfS into the Science and technology strand of primary teacher education is constrained in several ways that are consistent with previously documented problems in this area (e.g., Tilbury *et al*., 2005).

A reflection of these constraints is that, of the four recognised pillars of sustainability, we have really only dealt with ecological sustainability to any significant extent in these units. Although this is perhaps entirely appropriate for the Science and Technology disciplinary area, given the importance of making connections between aspects of ecological sustainability and other pillars of sustainability this could be viewed as a limitation. Despite the inclusion of an assessed activity designed for the students to make links between concepts across the four pillars of sustainability (based on an activity described by UNESCO (2006)), it is unlikely that the graduating students had had the opportunity to develop strong relational understandings within and between these broad themes.

This is, of course an issue because EfS is about connections: connections within and between trans-disciplinary sustainability issues and disciplinary content, connections between the different pillars of sustainability, as well as connections between schools and community, between knowledge and action, between people and place and between humans and nature. Of course, education more broadly is about connections, with connections between different forms of knowledge essential for meaningful, relational understanding. But students cannot make these connections all at once, because of well-recognised limitations to working memory (Demetriou, Christou, Spanoudis, & Platsidou, 2002) and because 'limitations to awareness' (Marton & Booth 1997) mean that students cannot be aware of all aspects of a phenomenon simultaneously. In the words of Paige et al. (2008) the disciplinary must precede the transdisciplinary. Which connections should be highlighted or take precedence by us as teacher educators and educators for the environment? Which connections are most relevant and beneficial for the pre-service teachers, who, as we know from several studies, avoid teaching science and technology because of a lack of knowledge and confidence about basic science concepts?

The connection between science and literacy established by the ‘Primary Connections’ project (Australian Government and Australian Academy of Science, 2010) is one direction that has already been established, because of the value of these resources and the pragmatic responses of teachers both lacking confidence in science and operating within a context of high stakes literacy and numeracy assessments. The existing focus on ecological sustainability in the degree programs clearly reflects the importance we have placed on the connections between the content knowledge in the units and the concepts specified in existing science and technology syllabus documentation. This strong emphasis should go some way to addressing ‘ecological illiteracy’ posed as a problem by Cutter Mackenzie & Smith (2003).

These connections are also directly relevant to what appears to be in the forefront of students’ awareness in the science and technology learning context (Marton & Booth 1997), namely, concerns that they have the appropriate conceptual understanding to facilitate primary students’ learning of scientific concepts and skills specified in the primary syllabus. Given the crucial importance of perceived relevance to the learning of tertiary students, this is an important consideration. Although environmental and sustainability concerns are also important for many of the students, the ‘limitations to awareness’ postulated by Marton and Booth (1997) foreground the more immediate, syllabus-mandated issues, leaving more relational, holistic issues related to sustainability more to the background. Yet in our view, it is equally if not more important and relevant for our students to understand the broader sustainability connections for themselves, and to help school children to make these connections.

While incorporating broad sustainability outcomes in tightly mandated and circumscribed professional courses is difficult to deal with, some of these problems can be ameliorated by better communication between teaching ‘silos’ and integration of EfS themes across disciplinary boundaries. Within the science and technology units, better integration of sustainability requires deliberate, sensitive and selective emphasis of broader, complex webs of sustainability knowledge and values with the more specific concepts and ideas, which are directly related to syllabus and accreditation imperatives.

Clearly, this is not enough for students to make the connections between the ecological, social, economic and political dimensions that we need them to make for a sustainable future. Bottom-up endeavours by committed educators for the environment can certainly enhance EfS within teacher education programs. What is needed, though, for these endeavours to be perceived as more directly relevant to both pre-service and in-service teachers and their accreditation agencies is a curriculum that explicitly incorporates sustainability outcomes. The extent of the success of EfS in the Australian National Curriculum will undoubtedly be influenced by assessment priorities given to curriculum content compared to processes, values and attitudes, as teachers’ practice is influenced by such priorities. It will also be influenced by the specificity, detail and amount of guidance provided to teachers in actually incorporating this cross-curriculum perspective, as well as the extent to which teaching emphases are driven by pressures associated with national literacy and numeracy testing. The potential consequences are exemplified by the relatively poor development of Environmental Education as a cross-curricular theme in the English and Welsh National Curriculum associated with its low priority for assessment in comparison with the core subjects (Littledyke, 1997).

CONCLUSION

Our endeavours to educate pre-service primary teachers about science concepts, about sustainability, about Education for Sustainability and **for** sustainability have focused on ecological sustainability, with much less emphasis given to economic, social and political aspects. This reflects the tension inherent between integrative, holistic approach espoused by many researchers in EfS and the constraints of disciplinary boundaries. While acknowledging the limitations of this approach, we will continue with this emphasis because of its direct relevance to the Science and Technology Key Learning Area and because of its perceived relevance to pre-service teachers, many of whom need to develop proficiency and confidence in scientific pedagogical content knowledge. In order for us and for our students to forge deeper and wider connections to other aspects of sustainability, the study has also highlighted the need to implement proactive communication strategies between teaching staff specifically for this purpose. The study has also raised for us the importance of repeated deliberate and strategic foregrounding of sustainability themes and links in our teaching that include and transcend the concepts of ecological sustainability. In this way we hope to assist our pre-service teachers to genuinely connect to the new National Curriculum's "Commitment to Living Sustainably' and to facilitate this commitment in the next generation.

ACKNOWLEDGEMENTS

We would like to thank the other members of the Education for Sustainability research team who contributed in various ways to this study: Di Hansford, Joy Hardy, Ros Littledyke, Bruce McMullen and Susen Smith. We are also very grateful to the members of staff who participated in the surveys and interviews. We also acknowledge funding from the Australian Government Department of the Environment, Water, Heritage and the Arts and Macquarie University via the Australian Research Institute in Education for Sustainability.

GENDER DIFFERENCES IN AUSTRALIAN STUDENTS' RELATIONSHIPS WITH SCHOOL SCIENCE

Frances Quinn

ABSTRACT

This paper explores issues of gender in Year 10 Australian students' experiences of science at school, their self-reported ability in science and their perceptions of science as a subject choice for senior secondary school. A sample of 3759 Year 10 students from across Australia responded to Likert-style questions related to these issues, with findings showing gender differences in perceptions of science, self-rated ability, and reasons for choosing not to study further science. Moreover, interesting contrasts were revealed in patterns of difference of self-rated ability for boys and girls across single-sex and co-educational schools.

Keywords: *Girls in science, boys in science, self-efficacy, gender differences*

INTRODUCTION

The interaction between gender and issues such as attitudes to science, self-efficacy, retention in science education and science subject choices has been a focus of educational research for many years. A review of the literature on science attitudes (Osborne, Simon, & Collins, 2003) suggests fairly unequivocally that although girls may be as competent as boys they continue to hold less positive attitudes to science, and continue to opt out of physical sciences in particular. This is also reflected in a more recent comprehensive review of girls in science (Brotman & Moore, 2008) . Similar findings continue to be documented in recent international studies. For example, Australian data from the Program for International Student Assessment (PISA) (Thomson & De Bortoli, 2008) showed statistically significant gender differences (predominantly in favour of males) for all but two of the indices reported. Boys reported higher self-efficacy in science than girls, and although there were no overall gender differences in scientific literacy, boys performed significantly better than girls in explaining phenomena scientifically, but significantly worse in identifying scientific issues. The Relevance of Science Education (ROSE) project reports (e.g., Schreiner & Sjøberg, 2007) did not include Australian data but found gender differences on many aspects of school students' attitudes to science.

From a different perspective, a recent meta-analysis of research studies has emphasised the similarities between boys and girls in performance and traits related to the ability to succeed in science (Hyde & Linn, 2009) and concludes that raising awareness of gender similarities would be more fruitful than 'cultural overemphasis' of gender differences. By contrast, Thompson & De Bortoli (2008) concluded their summary of gender differences in Australian school students with the comment that "perhaps gender needs to be reconsidered as an issue for Australian education".

Closely intertwined with issues of gender difference are conflicting views on the relative merits of single-sex and co-educational high school settings for boys and girls. Smithers and

Robinson (2006) suggest that single-sex schools have been viewed as a potential solution to gendered classroom roles of girls as the 'secretaries' and boys engaging with the equipment, and ultimately to the underrepresentation of women in science. Single-sex schools have also been seen as advantageous for self-efficacy in subjects such as science, however the evidence relating to this issue is mixed (Schoon, Ross, & Martin, 2007). Some research shows advantages of single-sex schooling, particularly for girls (Hoffman, 2002; Warrington & Younger, 2001).

Other studies question the value of sex-segregated schools. Smithers and Robinson (2006) found little advantage to students of either single-sex or co-educational schools, including no evidence that gender-related gaps in science subject choices were narrowed by single-sex schooling. Similarly, studies reviewed by Osborne et al. (2003) show that girls in single-sex schools were not more likely to elect to study physical sciences than girls in co-educational schools. Very little evidence supporting better educational outcomes from single-sex schools was found in a comprehensive analysis by Billger (2006). In fact, some claims have recently been made in the science media that co-educational settings are better for students overall and lead to improved grades, particularly for boys, which is partially attributed to better classroom environments (Tel Aviv University, 2008). A recent review (Chouinard, Vezeau, & Bouffard, 2008) has suggested that 'when students and school background factors are adequately controlled, there is no academic advantage of single-sex schools for girls' and that further research into these issues is warranted.

AIMS

Against this theoretical background, this paper reports findings from a study of Year 10 girls and boys (aged 15 to 16) from both single-sex and co-educational schools. The aims of this paper are to determine any gender differences in:

a) their intentions towards studying science in the following year (the first of two years of senior secondary school)
b) the reasons for their science subject choices for the following two years.
c) their perceptions of science as it is taught up to Year 10 and
d) their self-reported ability in science

METHODS

This study is part of a larger research project exploring students' decisions about taking senior science (Lyons & Quinn, 2010) and focuses on quantitative data from student responses to a subset of questionnaire items from the main project. A sample of 3759 Year 10 students from across Australia responded to an online survey. They were asked about their science subject choices for the following two years and responded to an array of Likert-style questions about their perceptions of science education and science careers, supplemented by some open-ended response questions.
The items that form the focus of this paper are shown in Table 1.

Table 1: Survey themes and associated items

Theme	Relevant items
• Reasons for not choosing science in senior secondary school	• I chose no science subjects because I am not good at science. • I chose no science subjects because science is more difficult than other subjects. • I chose no science subjects because I can't picture myself as a scientist.
• Liking of school science	• Test Of Science-Related Attitudes (TOSRA) Enjoyment scale (all items; available from Fraser (1981)) • I like school science better than most other school subjects. [This item taken from the Relevance of Science Education (ROSE) study (Schreiner & Sjøberg, 2007)]
• Self-efficacy	• How would you rate your own academic ability in science this year compared to others in your class?

In order to facilitate a concise visual representation of responses to the Likert-style items, some results are depicted in terms of means and standard errors. The mean responses to the TOSRA Scale were compared by ANOVA. However, although a large body of evidence endorses the robustness of parametric analysis of Likert-type responses (e.g. Glass, Peckham & Sanders, 1972; Jaccard & Wan, 1996; Neuman 1994; Zumbo & Zimmerman, 1993), including single Likert items in some cases (for discussion see Carifio & Perla 2007) we have restricted our analysis and reporting of potential differences between responses to single Likert items here to conservative use of non-parametric statistical techniques such as chi-squared contingency table tests.

Because of the large sample size and the number and types of statistical tests undertaken in the wider study, a conservative level of significance of $p \leq 0.001$ was adopted. In the case of chi-square tests, Cramer's V was used as a measure of effect size and interpreted according to Cohen's criteria (1988 cited in Gravetter & Wallnau, 2005 p. 475). For one degree of freedom, Cramer's V between 0.1 and 0.3 is interpreted as a small effect, between 0.3 and 0.5 a medium effect and greater than 0.5 a large effect. Adjusted Standardised Residuals (ASRs) were used to locate the sources of difference detected by statistically significant chi-square relationships. ASRs greater than +3.30 or less than -3.30 indicate significant differences (at 99.9% probability level) between observed and expected cell counts, while ASRs outside +/- 2.58 are suggestive of significant differences at 99% probability level.

RESULTS

SCIENCE SUBJECT CHOICES

There was no statistically significant difference between boys and girls in the frequency with which they chose no science at all for the following year. Gender differences were, however, evident in frequency of different subject choice categories [$\chi 2$ (3) = 227.9; $p<0.001$; Cramer's V = 0.30]. Girls chose physics (in combination with any other science) much less frequently than boys [ASR = +/-14.6]. Girls much more frequently chose biology without either chemistry or physics [ASR = +/- 9.9] and to a lesser extent, chemistry without physics [ASR = +/-4.2]. Some of these gender differences existed even among students who rated their science ability as "Much better than average" [$\chi 2$ (3) = 17.46; $p=0.001$; Cramer's V = 0.19]. Among these students, girls were still more likely than boys to take chemistry without physics [ASR +/- 3.5]. They still chose to take physics (in combination with any other sciences) less frequently than boys [ASR +/-4.0], but this gender gap was much less extreme than in the overall cohort. Amongst the students with the highest self-rated ability there was no statistically significant gender difference in the frequency of choosing biology or other science (without chemistry or physics), or choosing no science at all. There were no meaningful statistically significant differences between students from single-sex and co-educational schools in the frequencies of physics, chemistry or biology subject choices, for either girls or boys.

REASONS FOR CHOOSING OR NOT CHOOSING SCIENCE

There was no meaningful significant association detected between sex and reasons for choosing science in senior secondary school. By contrast, there were meaningful significant associations apparent between sex and three of the seven items relating to students' reasons for **not** choosing science. These results are shown in Figure 1.

As suggested by Figure 1, girls agreed significantly more frequently than boys with the statements "I chose no science subjects because I am not good at science" "I chose no science subjects because science is more difficult than other subjects" and "I chose no science because I can't picture myself as a scientist" [All items significant at $p<0.001$: $\chi 2$ (4): [a]= 36.12; Cramer's V = 0.20; [b] = 27.85; Cramer's V = 0.18; [c] = 20.00; Cramer's V = 0.15]. These differences, which all relate to the girls' perceptions of themselves, their ability and the difficulty of science rather than external issues related to careers, teachers or timetables, relate coherently to the girls' lower self-efficacy found in this study.

<table>
<tr><th>Item</th><th>Means and standard errors of item for boys and girls</th></tr>
<tr><td>I chose no science subjects because I am not good at science [a]</td><td></td></tr>
<tr><td>I chose no science subjects because science is more difficult than other subjects b</td><td></td></tr>
<tr><td>I chose no science subjects because I can't picture myself as a scientist c</td><td></td></tr>
</table>

Figure 1: Means and standard errors of responses of boys and girls to three items related to them choosing no science for the following year. [Response scale: 1 = Strongly disagree, 2 = Disagree, 3 = Unsure, 4 = Agree, 5 = Strongly agree]

LIKING OF SCHOOL SCIENCE

The TOSRA Enjoyment scale was reliable (α = 0.93) and comparison of scale means showed no meaningful significant difference between the responses of boys and girls. Although the mean response for boys was higher than that of the girls, [F(1,3755) = 10.156, p = 0.001], the effect size ($\eta p2$ = 0.003) was trivial.

The means and standard errors for student responses to the question "I like school science better than most other school subjects", broken down by sex, are shown in Figure 2. Mean responses below the mid-point indicate disagreement.

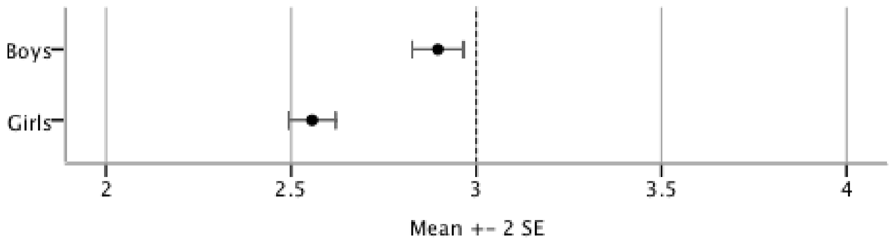

Figure 2: Means of responses to the item "I like school science better than most other school subjects" for boys and girls. [Response scale = 1 (disagree) through to 5 (agree)].

As shown in Figure 2, both boys and girls tended to slight disagreement with this item; on average, students did not like science more than other school subjects. Boys agreed with this item slightly more frequently than girls [$\chi 2$ (4) = 55.58; p<0.001; Cramer's V = 0.14]. For this item, there was no significant difference detected in responses from single-sex and co-educational schools, across the cohort as a whole.

Self-efficacy

The means and standard errors for students' self-rated science ability are shown in Figure 3.

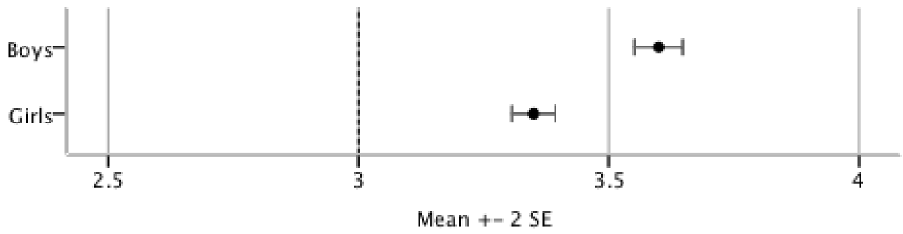

Figure 3: Means of responses to the item "How would you rate your own academic ability in science this year compared to others in your class?" [Response scale = 1 (Far below average); 2 (Below average); 3 (Average); 4 (Better than average) and 5 (Much better than average)].

As shown in Figure 3 the mean response was around 3.5, somewhere between Average and Better than average self-rated ability. Proportionately more boys reported having better or much better than average ability, and more girls reported average, below average or far below average ability in science [$\chi 2$ (4) = 79.47; p<0.001; Cramer's V = 0.15]. In particular, the percentage of boys reporting "much better than average" ability was double that of girls.

There was also a significant interaction between sex and school type (single-sex vs co-educational) [$\chi 2$ (4) = 79.47; p<0.001; Cramer's V = 0.15]. The interaction between these two variables is summarised in Figure 4.

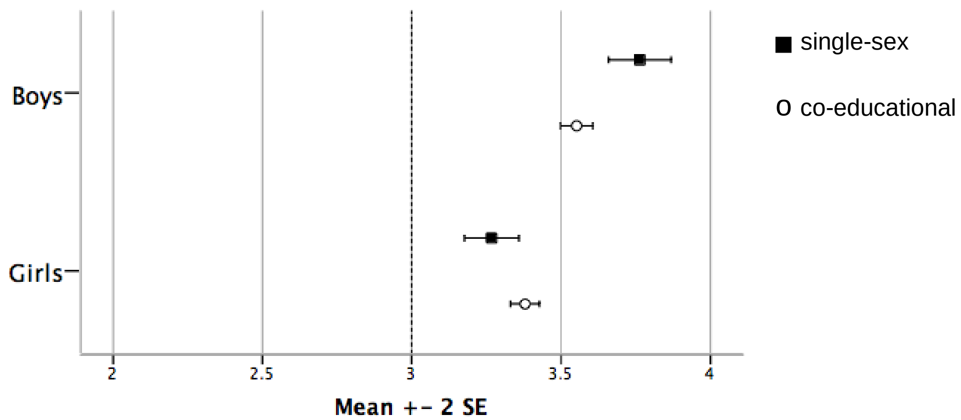

Figure 4. Means of responses to the item "How would you rate your own academic ability in science this year compared to others in your class?" broken down by sex, across school types (single-sex and co-educational. [Response scale = 1 (Far below average); 2 (Below average); 3 (Average); 4 (Better than average) and 5 (Much better than average)].

As suggested by Figure 4, proportionately more boys from single-sex schools rated themselves as "Much better than average", than did boys from co-educational schools and this difference is more than would be expected were there no association between school type and self-rated science ability [$\chi 2$ (4) = 19.85; p=0.001; Cramer's V = 0.10, ASR = 4.0, (p<0.001)].

This pattern was not evident in the case of girls, however, as is indicated by Figure 4. In fact there is suggestive evidence of the converse: proportionately more girls from single-sex schools rate themselves as “Below” or “Far below average” in comparison to girls from co-educational schools [$\chi 2$ (4) = 19.84; p=0.001; Cramer’s V = 0.10: ASR = -2.8 (0.001<p<0.01)]. There is certainly no evidence among the girls for the pattern of higher self-efficacy in single-sex schools seen among the boys, and in fact the tendency is towards the converse.

DISCUSSION

SCIENCE SUBJECT CHOICES

The results of this study highlight the continued importance of gender in students’ choices in and attitudes to science. That relatively few girls in this study chose physics, even among students rating their academic ability as “Much better than average”, is consistent with global trends that are persisting despite decades of research into the underrepresentation of girls in physical sciences (e.g., Adamuti-Trache & Andres, 2008), and at least a decade of emphasising more gender inclusive classroom practices, at least in the Australian context. Various explanations for this have been postulated (Brotman & Moore, 2008), ranging from early differential socialization of girls and boys relating to experience with and consequent liking for scientific tools and activities, to gender differences in the perceived need to conform to gender stereotypes, issues relating to the ‘masculine’ , objective and value-free way that science is portrayed in the classroom and complexities of identity formation. Recent research into the relationship between gender and identity construction (e.g., Eccles, 2009) and other aspects of science culture (e.g., Taconis & Kessels, 2009) appear to be providing useful lenses to clarify and interpret these complex interactions.

DIFFERENCES IN REASONS FOR NOT CHOOSING SCIENCE

That girls in this study reported more frequently than boys opting out of science because they could not picture themselves as a scientist, perceived themselves as not good at science, and perceived science as more difficult than other subjects forms a coherent picture consistent with previous research findings.

The issue of not being able to picture oneself as a scientist is of particular interest as this was the most frequently endorsed reason for not choosing science for the entire cohort. Girls have previously been found to be less likely than boys to envisage themselves as scientists (Steinkamp & Maehr, 1984) or to report that they would like to become a scientist (Schreiner & Sjøberg, 2007). A study by Fielding (1998 cited in Osborne 2003 p. 1063) found that even very high achieving girls did not view science careers as appealing. It has been argued that contemporary youth, particularly girls, develop through a series of choices an identity that does not involve science, which purportedly clashes with current societal ethos of self-realisation (Schreiner 2006 cited in Taconis & Kessels, 2009). A related perspective holds that students’ inability to picture themselves as a scientist relates to clashes between their own self-image and their negative perceptions of peers fitting the “science prototype” (Taconis & Kessels, 2009). Our findings highlight gender differences in this process that have received relatively little attention and warrant continued research.

That girls opted out of science because they were ‘not good at science’ to a greater extent than boys is consistent with their lower self-rated ability in science. It is not consistent, though, with recent reports suggesting that girls’ abilities in science and science performance are on a par with boys (Hyde & Linn, 2009; Brotman & Moore, 2008). For example, although there were some differences in boys and girls in different aspects of science, Thompson & De Bortoli (p. 68) found no statistically significant difference between scores of 15 year old Australian boys and girls in scientific literacy. In terms of perceived difficulty of science, studies reviewed by Osborne et al. (2003, p. 1070) indicate that students in general see sciences (especially physical sciences) as difficult, and that the perceived difficulty of science is a major impediment to students choosing science, especially physical sciences. Our findings that girls in particular opted out of science because they saw it as difficult is consistent with recent findings from a recent study of high school students in the UK which found that girls saw biology, chemistry and physics as more difficult than did boys (Bennett & Hogarth, 2009).

LIKING OF SCHOOL SCIENCE

The finding of no meaningful difference between boys and girls on the enjoyment of school science as measured by the 10 item TOSRA scale runs counter to many studies showing that girls hold less positive attitudes to science than boys (e.g., Barmby, Kind, & Jones, 2008; Bennett & Hogarth, 2009; studies reviewed by Osborne, et al., 2003, p. 1063, (Brotman & Moore, 2008)). The gender differences in responses of these Australian students to the ROSE item “I like school science better than most other school subjects” are consistent with responses to this item in culturally comparable countries (Schreiner & Sjøberg, 2007). The lack of statistically significant difference detected in this study of boys’ and girls’ enjoyment of school science *per se* is of interest in relation to the finding that boys endorsed the ROSE item more than girls. While interpretation needs to acknowledge that one finding was from a reliable scale and the other from responses to only a single item, this issue perhaps warrants further investigation. At face value it highlights the relational aspect of students’ enjoyment of science: that boys and girls enjoy science to a similar extent but that girls do not enjoy it in relation to other subjects to the same extent as boys. This may reflect girls’ greater enjoyment of arts and humanities relative to boys, as has been suggested by Jovanic and King (1998, cited in Osborne, et al., 2003, p. 1063). Perhaps girls do not enjoy science less, they enjoy other subjects more.

SELF-EFFICACY

That boys in this study reported higher self-efficacy in science more frequently than girls is in accord with other research including PISA 2006 results (Thomson & De Bortoli, 2008). The differences in self-efficacy found between single-sex and co-educational schools for both girls and boys are particularly interesting. Although the findings supported the notion that higher self-efficacy in boys was more frequent in single-sex than co-educational schools, there is some evidence that high self-efficacy in girls was in fact less frequent in single-sex than co-educational schools.

We would argue that the more frequent higher self-efficacy reported by boys in single-sex schools is consistent with established research models from a number of slightly different perspectives. Such research includes models of the interactions between psychosocial influences and self-efficacy (e.g., Bandura, Barbaranelli, Caprara, & Pastorelli, 1996), and, from a sociocultural perspective, the impact of cultural and social capital (Lyons, 2004). To elaborate, single-sex schools in the Australian context are generally independent private schools, which attract families from relatively high socio-economic backgrounds. In Bandura’s model, higher socio-economic status is linked to higher parental aspirations, which are also associated with children’s higher self-efficacy. From a sociocultural perspective, the cultural and social capital often associated with higher socio-economic status also relate to self-efficacy and enrolment decisions. Hence the more frequent high self-efficacy for boys in single-sex schools is not a surprising result. The question this finding really raises is, why was this relationship not found for girls?

One possible explanation is that girls’ perceptions of their ability in relation to their peers are enhanced in co-educational settings. Given the evidence of relative parity in the competence and performance of boys and girls in many (although not all) aspects of science (Hyde & Linn, 2009; Osborne, et al., 2003; Thomson & De Bortoli, 2008) it is unlikely that girls’ perceptions of better relative ability in co-educational schools are a consequence of better relative performance. What does seem to differ between boys and girls at school is that boys' levels of physical activity and aggression are higher than girls' (Hyde & Linn, 2009). It is possible that girls may be comparing their ability favourably in relation to boys in co-educational settings as a consequence of what they observe in the classroom. In more general terms, to the extent that perceived ability is related to students' developing self-image, having boys as well as girls in the science classroom is a different 'context' of peers against which girls may be establishing a more positive sense of their own ability.

It has been suggested by Brotman & Moore (2008) that a joint focus on identity-construction and curriculum from a situated cognition framework would be a fruitful direction for science education research. The results of this study support this view, and specifically highlight the need for further research into the development of, and relationships between perceived ability, identity and self-image in relation to different school science contexts.

ACKNOWLEDGEMENTS

We gratefully acknowledge the support of the Australian Science Teachers' Association and the National Centre of Science, ICT and Mathematics Education for Rural and Regional Australia (SiMERR Australia) in facilitating this study. We would also like to thank all the students who participated in the study.

ABSTRACT

This paper is the result of an experience developed in elementary school, aiming to introduce Modern and Contemporary Physics themes from a historical-philosophical approach. The proposal was performed during one school year with 10^{th} grade students during 36 weeks. The purpose was not to introduce a new methodology but to privilege a historical-philosophical approach as to make the knowledge dealt with in Physics classes in elementary school more significant. In order to evaluate the consequences of this pedagogical experiment a qualitative research was developed. The data collected by the teachers through films, photos and notes during lessons.

The purpose of this paper isn't to evaluate how much physics the students have learned. What we want only to evaluate is the impact of the cultural approach. Therefore, it is difficult to quantify how much the students learned about science, history, philosophy and art. But we can say that this cultural approach allowed the teacher to discuss science in a different way. The students had an opportunity to think about the scientist's work, recognizing that the scientist isn't a man isolated in his laboratory discovering the truth about the Universe. The scientists which the students studied in the course do right and wrong things like a common man.

Keywords*: Science Education, Interdisciplinary Approach, Nature of Science, History, Philosophy.*

INTRODUCTION

In Brazil, the study of Physics in both elementary and high schools does not contemplate the developments of Modern Physics. The purpose of this paper is to discuss a Physics course developed within a Brazilian school. During this development, the students' scientific horizon was broadened when themes on Modern and Contemporary Physics (MCP) were approached from a historical-philosophical point of view. It is important to notice that our purpose was not only to introduce new themes of MCP but also to allow a discussion of contemporary themes through a cultural perspective, stimulating the students to think about the process of knowledge construction. We want the students to be able to recognize science as a knowledge constructed by people immersed in a specific culture.

Science teaching in primary schools must be stimulating so students develop a keen interest in science and perceive the philosophical and cultural implications of scientific knowledge (Mathews, 1994)

In order to do this, we pursued two paths which converged for a common objective. The first path was to use MCP themes from an interdisciplinary perspective, privileging the cultural context of different periods approached in the lessons. In such a way, the construction of an historical panorama allowed students to understand that scientific knowledge is immersed in an environment with which there is a symbiotic relation: scientific knowledge simultaneously builds this environment and suffers influences from it.

MCP themes are important in Physics lessons in high school as they allow students to apprehend certain subjects, providing them tools to understand the surrounding technology; these themes are also important in order to develop greater knowledge on what Physics is doing nowadays. (Terrazzan 1992; Stefanel 1998; Osterman, Moreira 2000).

The second path used for the introduction of MCP themes was to render problematic the classical vision of the world, and therefore discuss the philosophical and conceptual transformations which were implemented by Physics in the 20th century as the discipline explained the universe functions.

The proposition we developed overcomes a technical approach in which the emphasis of Physics teaching is in resolving exercises. In contrast, we discussed with the students how scientific knowledge was built through the centuries, particularly the knowledge on celestial bodies and their movements and origins. The privilege for an interdisciplinary approach allowed a dialog between science and culture, perceiving Physics itself as a part of culture (Zanetic, 2006).

The historical approach was done in such a way as to outline how humans built explications for the way the universe functions.

METHODOLOGY

Since 1993 a group of teachers and researchers in science education from Rio de Janeiro-Brazil (Teknê Group) works on the construction of a program with a historical-philosophical approach for science education. The Teknê Group argues that the introduction of an approach of History and Philosophy of Science in the program could allow the discovery of new paths in this direction. As History and Philosophy of Science become widely perceived as parts of culture, it is possible to cross boundaries between different forms of knowledge (Fleck,1981)(Kuhn,1996).

In Brazil the school content program is open. There are parameters to guide the work of teachers, with skills and abilities that are expected of students at the end of a learning period. However, there isn't an enclosed table of contents to be taught. Therefore, it is possible to introduce new contents in the program. The Teknê Group develops educational practices in Brazilian schools, allowing students to learn new contents like cosmology, and constructing a more signifying and stimulating approach for Physics lessons.

The pedagogical propose was carried out in a 10th grade class during 36 weeks. In that grade, the school has 3 classrooms, each one with 33 students, aged 14 and 15. Most students belong to the middle class and live in several different neighborhoods of Rio de Janeiro The students have 4 fifty-minute periods every week to study physics. Cosmology was studied in only one of those periods, whilst in the other periods the students had optical lessons. Hence the teacher, a member of the Teknê Group, had fifty minutes a week to work with the students. The teacher occupied the time presenting the subject, correcting the exercises and applying evaluations of the students' work.

We chose to work with this grade because, in Brazil, this is the first time that students study physics formally. So this is a good opportunity to discuss themes that stimulate the imagination of the students, like the origin of the Universe.

This school has a program that stimulates a cultural approach. The students have theater, cinema and environment project classes. The teachers were stimulated to bring new pedagogical experiences to the classroom.

In order to evaluate the consequences of this pedagogical experiment a qualitative research was developed. The class teacher was a member of Teknê´s Group and became also a researcher. Another member of Teknê's Group watched the work to the teacher during 36 weeks. This researcher joined the class two weeks before the beginning of the project itself. This previous contact had two objectives: the first, to get to know the reality in which the project would be carried out; and the second to ease the possible feeling of discomfort/strangeness from the students in relation to the presence of someone new in/to the group. Data was collected through films, photos and notes made during the lessons. As the researcher joined the group of students, it was possible to register the students' participation in and out the classroom.

The teacher kept a diary in which he registered his impressions of the class after each meeting. The teacher's and the researcher's registrations and the films were discussed with the project group weekly. This way of interacting resulted in a pedagogical proposal with an initial plan, but which was constantly reoriented.

THE COURSE

The main purpose of the cosmology course described above was to discuss the contemporary models about the origin of the Universe. Researches show that students have a wrongful idea of science (Abd-El-Khalick, Lederman, 2000; Fernandez 2000; Gil-Perez et al., 2001). For them, science is performed by a special man who works alone in a laboratory, discovering the truth about the Universe. With this idea, the students hope that the science teacher will tell them the truth about the Universe. Thus for the students it is difficult to recognize that cosmology models weren't built randomly, and that these models do not mean that we have the truth about the origin of the Universe. With models we can explain how the Universe began without considering God's creation. To overcome this difficulty, we built the course with a historical approach. The proposal is to allow students to understand that scientific knowledge is immersed in an environment with which there is a symbiotic relation: at the same time scientific knowledge builds this environment and also suffers influences from it. So the truth is temporary, but scientific knowledge isn't random.

With these considerations we divided the course in five themes.

1- Classical and Middle Age Astronomy

The first theme discussed was Greek and Middle Age Astronomy. Here, the focus was upon the ideas of Aristotle about how the universe functions. The students understood that Aristotle considered the Universe separate in sublunar and supralunar worlds. All things in the sublunar world were constituted by four elements (earth, water, air and fire). With the natural and violent movement classification, the philosopher explained the movements that occur in the sublunar world. In addition, we discussed how Aristotle based his movement explanation on the observation of nature, but also that he didn't make experiments in the modern sense. Then, the Ptolemaic system was used in order to comprehend Middle Age Physics and Astronomy.

The Ptolemaic system was studied as a good way to describe celestial movement and also as anticipation on the knowledge about celestial bodies. At this point, the European cultural context in the Middle Age was discussed with the students. To do this, we developed activities in which some medieval paintings were showed. The spatial conceptions in medieval paintings were approached in order to outline the hierarchical concept of space, and to explain to the students how this was coherent with the vision of natural philosophers which based their ideas on Aristotle (Edgerton, 1993).

2- Modern Astronomy

To begin the study of Modern Astronomy, the students saw the film "The Name of the Rose" based on Umberto Eco´s homonymous novel. Using the film to illustrate the changing European world, the teacher selected some scenes to discuss the European society in the 12th century. The students understood how a new way of constructing knowledge was being formed. In that cultural context, some people argued that in order to understand something it is important to do empirical investigation, to ask the nature of how things occur. The dialogue about the film was used to outline the dialogue between the Arabian and European cultures, and how this dialogue put the European in contact with new techniques, like windmill and horse harnessing.

After the debate about the film, the students were again asked to analyze medieval paintings. The teacher compared medieval pictures with the paintings of Giotto and his followers, showing that a new arising spatial concept was being formed along with the changes in society. After Giotto, the artists built tri-dimensionality and spatial infinitude (Edgerton, 1993).

The film's activity was a special moment in the course. The film showed a world far from the students. We used this moment to discuss the role of the Church in the development of the modern science. The students became very enthusiastic with the lessons and some of them were amazed with the Franciscans that appear in the film. For the students, religious people of the Middle Age were far away from science.

In one of the three classrooms, a group of students talked to the History teacher about the activity. They wanted to discuss the relationship between Church and science in the Middle Age.

ACTIVITY 1

The teacher used this special moment to present the Copernican system and compared it with the Ptolemaic. The objective was to discuss those scientific questions which the Copernican system answered better than the Ptolemaic, and those questions which the new system couldn't answer. In this perspective, the teacher asked the students which model is better. 77 students (87,9 percent) said that the Copernican model is best and that the Ptolemaic model is naive. 12 students (12,1 percent) didn't answer the question.

The teacher, then, asked them to prove that the Earth was moving around the Sun. Nome of the students presented arguments to prove that the Earth was moving.

As modern astronomy was approached, we outlined the difficulties to accept the Copernicus system due to the lack of physics suitable to replace the Aristotelian physics. With this, students were able to perceive how the permutation of positions between the Earth and the Sun was no easy task.

After discussion, the teacher asked the students to write a text, in groups of three, comparing the two astronomical models. 55 percent of the students said that there was a necessity to propose a new way to explain the movement of bodies in a world in which the Sun was the center. They didn't know how to explain, but they realized that Aristotle explanations were not good enough and some change in the physics were necessary to accept the Copernican model.

3- Classic Physics

In order to study Newtonian physics, the teacher discussed the 16th century cultural environment in Italy. Renaissance paintings were used to illustrate the perspective technique, emphasizing that the artists didn't represent a hierarchical world in their paintings. In this new representation, space was infinite and there wasn't a separation between the terrestrial and the celestial world. For example, Leonardo da Vinci painted a scene, "The Last Supper", which was represented several times by medieval artists. In the medieval paintings Jesus was represented in a bigger size in order to put him in evidence. Da Vinci, on the other hand, built this emphasis by putting the vanishing point inside Jesus' face. The size of the figure in the painting only obeyed the perspective technique. The space in the Renaissance painting was homogeneous, infinite and isotropic. The sky and the earth were painted with the same color. Beside this, the teacher discussed with the students the role of technique and mathematics in the 16th and 17th century (Janson, 1995).

ACTIVITY 2

The teacher presented two pictures to the students (figure 1 and figure 2). He asked them what the meaning of those pictures was. 100 percent of the students recognize the moon in the figure 1. But the figure 2 was not identify.

"I see a bacterium into a microscope". (student)
"It's a little boy on the top of a mountain" (another student)

In order to systematize the discussion the students read a text written by the authors of this paper. The text presented the world which surrounded Galileo and emphasized his choice to write in Italian, to use the dialogue form in his books, and his thoughts on experiment. Galileo was a citizen who was able to put the scientific knowledge beside the artistic. He studied drawing in Italy. Because he knew the perspective technique he was capable to see, in 1609, craters in the moon with his lunette (figure 1). At the same time, Thomas Harriot (1560-1621) used a similar lunette to look at the sky. He saw the sunspots, but he couldn't see the craters of the moon (figure 2). For him the moon had spots like the Sun. Because he didn't know perspective technique, Harriot couldn't interpret the scale of the dark like a shadow. Only after knowing Galileo's draw he was able to understand what he saw with the lunette (figure 3).

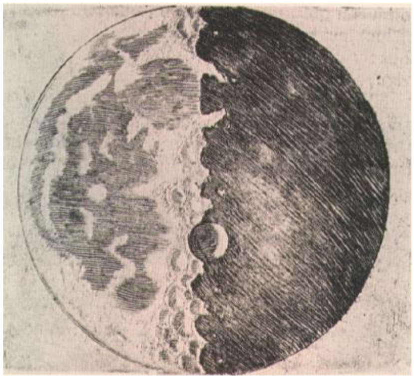

Figure 1-This is the design made by Galileo about the moon's observation.

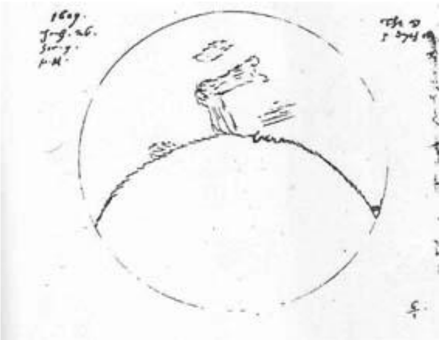

Figure 2- This is the design made by Thomas Harriot about the moon's observation.

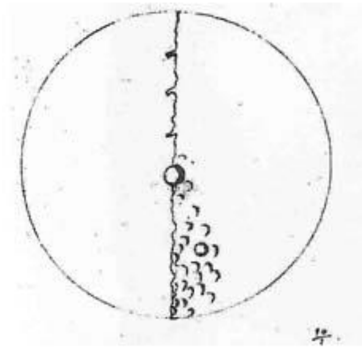

Figure 3- This is the second design made by Thomas Harriot about the moon's observation with the lunette. It's important to note that this design didn't have the quality of the Galileo's draft. Harriot didn't have technique to do a design with the perspective's technique.

After explaining the difference between two pictures (1 and 2), the teacher showed the figure 3. All of them identified the moon. This is a good example of the fact that we don't see only with the eyes. There is an important contribution from the socio-cultural construction to what is seen by people.

Beside the Galileo, students investigated Kepler's work and his desire to construct a physics to explain how the celestial bodies move. Kepler's laws were studied along with the questions that Galileo and Kepler couldn't resolve. The teacher emphasized the need of a new physics to give up Aristotle's and Ptolemy's system.

With this discussion, the Newtonian physics was presented. This study led to discussions on how this new theory allowed answers for all questions which could still persist in relation to the heliocentric system. This new physics was also the possibility to unite the analysis of terrestrial and celestial phenomenon.

Before beginning the fourth theme, the teacher held activities with the students to evaluate the work done so far. With this the teacher wanted to verify if the students had learned the astronomical models discussed in classes, and also the students' views on the construction of scientific knowledge.

ACTIVITY 3

In one of these activities, the teacher gave the students a black box with a hole and a crank. Inside the box there was a mechanical system. The students put a pen in the hole and turn the crank. Then, the pen starts to go up and down.

In the beginning the students insisted to open the box (100 percent).

The teacher explained that it is not possible to open the box. He asked them if it would possible to know what there is inside the box. 66 students (66,7 percent) answered No and 23 students (22,3 percent) answered YES.

Divided in small groups, the teacher mixed the students who had said NO and YES. The students were invited to try to construct a model explaining the box's operation. In order to do this they could manipulate the box, but they couldn't open it. After some time, each group presented its model in the blackboard and argued about their idea.

The teacher used this activity to discuss that, similarly to the black box, nature doesn't open up for scientists. In order to construct scientific knowledge, scientists do experiments, build theories, and construct experiments based on their theories, but they never have nature opened to them. Based on the astronomical models studied in class and in the student's discussions to construct their models, the teacher discussed how scientists make experiments in order to build theories, but not only with experiments have they built their work. They don't work alone in a laboratory to discover how the world works. The culture that they were immersed in was important for their efforts.

4- Kant and Laplace Cosmological Systems

Using the historical approach discussed in the first three themes, the teacher showed that scientists in the 16th century, such as Copernicus, Galileo and Kepler, didn't propose a cosmological theory; they didn't worry about the explanation of the beginning of the Universe. With the Newtonian system the situation reverses.

After the study of the Newtonian system, the teacher explored the scientific and cultural dimensions of Newtonian thinking and its impact on Western philosophy. After the 17th century, everyone considered space as tridimensional, homogeneous, isotropic and infinite. The Newton's Law of gravitation allowed people to understand, with a single explanation, what happens in sky and earth. Scientists now had only one physic for the celestial and terrestrial world. Newton did what Galileo and Kepler looked for with their work, a single physics for heaven and for earth.

Immanuel Kant (1724-1804) proposed a theory about the origin of the solar system based in the Newtonian law of Universal Gravitation. For Kant, the Newtonian system provided a model to understand the origins of the Universe. Differently from Newton, Kant didn't suppose that God was regularly infusing nature. In order to explain the origins of the solar system, Kant considers that in the beginning there were random particles in the world, like a nebula. Gravitation attraction joined heavier particles in the middle, and then the Sun was formed. Around the Sun others particles began to circle, and again gravitation attraction put particles in groups that formed the planets.

Kant didn't explain how these particles began to move. Nevertheless, with Kant a new era in astronomy began. He explained the origin of solar system without mentioning theological arguments (Kant, 1946).

In the same way, Pier Simon Laplace (1749-1827) built a similar model to explain the origins of the solar system. For him, in the beginning there was a ring of particles. Suddenly the ring broke and the heavy particles come together because of gravitational attraction, so the Sun was formed. The other particles around the Sun were agglutinating too, as gravitational attraction put them together and formed the planets (Laplace, 1946).

The teachers discussed the thesis of Kant and Laplace. The students had been studying Kant in Philosophy classes, so they knew him as a philosopher. They were surprised with Kant's scientific studies.

The students noted that the two propositions (Laplace and Kant) were very similar. Both of them were based in Newtonian law of gravitation, and both didn't explain how the particles appeared in the first moment. The teacher discussed in class how with these propositions astronomers had the possibility to build an explanation about the origins of the Universe without God's hands. The path for modern cosmology was opened. In this context, scientist didn't have any doubts about the center of the Universe. It wasn't a problem anymore. Now the issue was how the stars had been formed. They built new telescopes to study the stars, which became the first concern, with planetary astronomy in second plain.

5- Contemporary Cosmology

In this topic, the emphasis was put upon the changes in space-time conception brought by Einstein through the Theory of Special and General Relativity. For the study of the General Relativity the teacher emphasized Einstein's consideration that physics laws were the same for all referential. This came together with the idea that space is modified by matter, and that it was possible to think about a curved space around the planets, the stars, and all heavy bodies.

In the 19th century, mathematicians put Euclidian's geometry in question. They built geometry to be used in a curved space. The Euclidian geometry was valid for a plane space. In the 19th century, mathematicians imagined the possibility of constructing a geometry which was able to represent a curved space. They didn't worry to put this space in a concrete way, since for them the most important thing was to think of all possibilities to represent the space. So why not think of a curved space?

The question about space representation wasn't a priority for mathematicians. It was the artists, especially painters, who put the representation of the space in question. The impressionist artists in the 19th century questioned the homogeneous and isotropic space. Impressionists' paintings, such as the ones by Cezanne and Manet, represent scenes in which the space was not homogeneous, nor isotropic. In the same way, Claude Monet put time in his representation (Shlain, 1991).

After the presentation of the Theory of General Relativity the teacher discussed with students two most important cosmological models in the XX century: Stationary Universe and Big Bang.

To begin this study, the teacher showed observations made by Vesto Slipher in 1917 with the new telescopes. Vesto Slipher concluded that the Universe was in expansion. In that moment, there wasn't any theory which supported his observation. Einstein and his contemporaries considered that the universe was homogeneous and isotropic. In this thesis the expansion wasn't possible, and the Universe would be stationary (Crowe, 1994).

The equations derived from the Theory of General Relativity showed a Universe in expansion. Einstein considered that these equations were wrong, and something had to be done. He modified the mathematical expression and introduced a cosmological constant in the equations. The Universe became stationary.

> In the first moment the students were amazed with these episodes.
> "How could Einstein be wrong?" (student)

The teacher used the development of the astronomy discussed in the first three themes to emphasize that the scientist isn't a special man who discovers the mystery of the Universe. His work is immersed in an environment with which there is a symbiotic relation, as at the same time scientific knowledge builds this environment and also suffers influences from it. Facts are important to the scientist, but mere facts don't make a theory.

The teacher discussed how Einstein was wrong and how in 1922 another scientist, Alexksander Friedmann, rejected the cosmological constant created by Einstein and defended that the Universe wasn't stationary. Einstein and the other major cosmologists rejected these hypotheses. Einstein considered, for example, that Friedmann's mathematics analysis was wrong. Friedmann proved to Einstein wrong, but he died in 1925 without the acknowledgment of his work (Singh, 2006).

In 1927, the Catholic priest Georges Lemaitre, without knowing Friedmann's proposal, but inspirited on the Vesto Slipher' work, defended: if the General Relativity was true, there was a beginning in the Universe, a start point. He imagined that all stars were together in a primeval atom and, at some point in time, the atom decay occurred and the history of the Universe began. For him this beginning was "a day without yesterday". In 1927, in the Solvay congress, Lemaitre talked to Einstein about his work; Einstein didn't accept the idea of the expansion of the Universe. For him, Slipher, Friedmann and Lemaitre were wrong.

In 1929, Edwin Hubble (1889-1953) used astronomical data to build a graphic which compared the distance of the galaxies with their velocity. These data allowed him to construct an equation that showed that the galaxies' velocity is proportional to the distance that separated the galaxies. In 1931, Hubble published a paper to defend the expansion of the Universe.

Einstein, in 1931, admitted that the cosmological constant was his biggest mistake. The Universe isn't stationary, and the galaxies are separating from each other.

CONCLUSION

This proposal which privileged the discussion of MCP from a cultural perspective was very well received by the students. In the last class, the teacher demanded the students to do an assessment of the course. In each classroom, the teacher put the students sitting in a circle, and asked them to describe the most important thing in the Cosmology classes. 61 students said that they liked the activities. For them it was the first time that they discussed History and Arts in Physics classes. 45 students defended that the course was good because they studyed a theme that they had seen on television and had curiosity to learn more.

It is curious that there was an initial resistance by them. In the beginning of the course, some of the students asked the teacher about the point to study theories that were wrong. They thought that wasn't necessary to think about the pass in a physics class. But after some activities like the film The Name of the Rose and the black box activity the students became more enthusiastic with the course.

In spite of this enthusiasm, we can't conclude that the students learned more physical concepts than a course without the cultural perspective. The analysis of data taken from films, photos and teacher's notes, shows that students were very participative in classes. They discussed all the themes proposed by the teacher and they didn't refuse to the activities. So the cultural approach allows students to discuss science and its construction process.

The other physics teacher, who managed the optical class, declared that great number of students, around 40 percent, didn't want to do the activities that asked them to. The students asked him why the optical class only discusses physics. They wanted to know who constructed the optical theories and where and how they lived.

The purpose of this paper isn't evaluated how much they learn in physics. What we want only to evaluate is the impact of the cultural approach. Therefore, it is difficult to evaluate what the students learned about science, history, philosophy and art. But we can say that this cultural approach allowed the teacher to discuss science in class in a different way. The students had an opportunity to think about the scientist's work, recognizing that the scientist isn't a man isolated in his laboratory discovering the truth about the Universe. The scientists which the students studied in the course do right and wrong things like a common man.

So we can conclude that the introduction of new contents, like cosmology themes, in parallel to historical, philosophical, and cultural perspectives allowed students to have contact with a more signifying study, providing also a greater articulation between different fields of knowledge.

ABSTRACT

There is a lack of courseware for the teaching and learning of primary sciences in an Education for Sustainable Development (ESD) approach. This shortcoming determined the organisation of a multidisciplinary team with different competences (on Science Education, Educational Technology and Design) for the development of the *Courseware* Ser$_e$ "The Human Being and Natural Resources".

Adjusting some principles of software's development, as far as User Centred Design (UCD) is concerned (Costa, Loureiro, Reis, Sá, Guerra e Vieira, 2009; Guerra, 2007), in an ESD approach (Sá, 2008) and according to relevant science education perspectives (Cachapuz, Sá-Chaves & Paixão, 2004), this multidisciplinary team collaboratively developed the digital educational resource, which integrated several *software* typologies within the educational activities. A full presentation of the development process of this digital educational resource will be done throughout this paper.

Keywords: *Courseware, natural resources, sustainable development**,** science education, primary school level*

INTRODUCTION

In the current world context, the adoption of sustainable attitudes will depend on the understanding each citizen has of the interactions between science, technology and society and how these affect environmental and economic contexts. The volume of scientific and technological knowledge available to mankind today leads to profound social, political, economic, environmental and cultural changes. Science and technology are, therefore, crucial components that allow for the understanding of the multiple dimensions of contemporary problems.

Holistic and systemic understanding of planetary situation and awareness of the importance to mobilize attitudes that promote both local and global change, depends on the understanding of sustainability and of it implications in the educational context. In the United Nations perspective, educating for sustainability is to educate for responsibility, solidarity and cooperation (UNESCO, 2005). Moreover, the combination of Education for Sustainable Development (ESD) and Science Teaching (ST) with a Science/Technology/Society educational perspective (STS) since the first years of schooling appears as an essential condition for a responsible citizenship.

UNESCO guidelines (2005) for education for sustainable development implementation (EDS) highlight teacher training as one of the essential aspects to the practice reorientation. Teacher training will have to be considered as a privileged means for reflection, not only on the contents and the type of interrelations between them but, essentially, on how to take this approach in practice. Innovative practices in this domain are not possible with methodologies based on information transmission.

ESD implementation through information and communication technologies (ICT) used as new learning spaces is recommended by UNESCO (2005). These technology tools, since they allow the exchange of views and sharing of experiences, can be integrated by teachers as a resource of interaction between students and between students and teachers, as mediator and facilitator of science learning. On the other hand, the student's search, selection and arrangement of information, together with the simulation of scientific and technological phenomena (included in the software), can enable exploration and testing ideas, vital in science education, in an ESD perspective (Sá, Martins, Loureiro & Vieira, 2006).

However, according to the *"Science teaching in schools in Europe. Policies and research"* report (Eurydice, 2006), regarding ICT integration in Science Education field, researchers' attention has focused primarily on the use of the computer as laboratory tool and for simulation purposes. In addition, there is a lack of quality resources for science teaching and learning according to an ESD perspective. This led to an effort towards the development of methodologies which, in turn, imply their continuous and intrinsic assessment so that they match the user's needs and capabilities (Gomes, 2000; Guerra, 2007; Sá, 2008). This is the action line that fits the Courseware Ser_e development.

The Courseware Ser_e was designed by a multidisciplinary team of researchers from the Department of Didactics and Educational Technology of the University of Aveiro, in partnership with Ludomedia (portuguese software development company). Created in the context of Science Education, within the framework of ESD, it responds to a need for quality computerised didactic resources for the 1st and 2nd Cycles of Portuguese Basic Educational System (children from 6 to 11 years).The educational resource was designed for student and teacher classroom use, although its exploration can be adapted to other levels of schooling and education contexts, such as non-formal and informal. This computerized educational resource includes a set of educational activities regarding the relationship between human activity, the natural resources use, energy and the environmental, social and economic long term consequences of such use. The activities proposed, the sequence suggested and exploration and learning purposes aim to create the conditions for cognitive confrontation and problem/questions definition.

This paper presents: 1) the development and research methodologies fallowed; 2) the Courseware Ser_e structure and 3) the Courseware Ser_e educational methodology.

1) DEVELOPMENT AND RESEARCH METHODOLOGIES

The development process of the Courseware Ser_e included four main steps:

-Step 1, *Educational guidebook planning*: the first stage demanded from science didactics and educational technology researchers the drawing up of a document establishing the students level, the thematic and didactic purposes, as well as the aspects relating to architecture, navigation and resource screens design. This phase also let to trade mark and patent the courseware, as well as, amongst others, a set of agreements concerning authorship rights.

-Step 2, *Storyboard design*: at this stage, educational activities and disciplinary content, defined in the previous step, were harmonized with the software interaction aspects, particularly the navigation and interface, with the collaboration of the designer and programmer from Ludomedia. As stated by Carvalho (2003), the resulting scenarios are considered essential to the understanding of the resource utilization context and to represent some of the interactive software situations.

-Step 3, *Didactical resource implementation*: this step was divided in two simultaneous stages. Firstly, the technical part, which corresponds to the software design and programming, as well as of its users manual. Secondly, the didactical part, requesting detailed specification of several aspects, in addition to those already specified in the storyboard (as the initial animation and students and teachers' guidelines). Through this task, the multidisciplinary team tested and adjusted the contents of the student and teacher guidebooks, which involved earnest collaboration of all elements, made either in person or online.

- Step 4, *Evaluation*: seeking to assess both the didactical resource as its development process, it occurred transversely through all the stages listed above. At the end of step 2, the storyboard assessment was carried out by external elements: primary level students, basic education teachers and science didactics and technological education researchers. Furthermore, the first Ser_e version assessment was also made during hands-on workshops (with a maximum duration of 120 minutes), trough an evaluation tool - a questionnaire - designed and implemented by team members. Each workshop included a group of potential heterogeneous users of the resource. The tool consisted of 3 parts: the first part of the evaluation questionnaire is divided in two groups with closed questions about the educational potential of Courseware Sere: (a) the first list of issues related to user interaction with the software; (b) the second concerns aspects on activities designed for didactic use. The second part is targeted at open answers and aims to achieve a synthesis on the relevance and potential evaluation of educational Courseware Sere. Finally, the third part, is seeking comments about the working session and evaluation tool (Costa *et. al*, 2009).

The Courseware Ser_e development process was guided by a reference theoretical framework especially centred in Primary Science teaching and learning, oriented by ESD guidelines, and using an UCD method. These were essential to carry out such rigorous research and to guarantee that the usability principles of the software conception were respected.

Taking into account the UCD and usability premises, the team aimed at finding the answers for two research questions: "What are the positive and/or negative perceptions of the "external evaluators" concerning the storyboard?" and "What are the potentials and constraints that emerged from the methodology adopted in the development of Courseware Ser_e?".

A qualitative method, of a descriptive and exploratory nature, was adopted in order to develop and evaluate the technical and didactical quality of Courseware Ser_e (question 1), as well as, the potential and/or constraints of the methodology adopted in its development (question 2). The development and research study was divided in two research phases, each with a set of different techniques and instruments to collect and, subsequently, analyse the data (Bardin, 2000; Bogdan & Biklen, 1994; Carmo & Ferreira, 1998). As far as data collection is concerned, throughout the process of Courseware Ser_e development, the researchers chose participant observation as well as interviews, questionnaires and the analysis of teachers' diaries.

Data analysis allowed us to identify the positive aspects of Courseware Ser_e, which are related to the educational potential of such a teaching resource in the teaching and learning of Science. Nevertheless, the external evaluators also identified negative aspects, mainly those connected to the conception of some scenarios, namely: some graphical elements are not very perceptive; the interactivity of some screens should be increased; some contents presented may be too complex for students of the first cycle and the vocabulary used may be difficult to understand for some students.

It was also possible to qualify the potential of the work within a multidisciplinary team, for example, the appropriation of several elements for the conception of the storyboard. The participation of external evaluators was also identified as a positive aspect in the stage of Courseware Ser_e storyboard development.

As far as teamwork was concerned, the obstacles identified during the evaluation were mainly related to the communication process amongst its members. The study undertaken contributed to the improvement of the storyboard, as well as of the strategy adopted in the development of Courseware Ser$_e$, previous to the technological conception stage.

2) COURSEWARE SER$_E$ STRUCTURE

Courseware Ser$_e$ is the result of the above mentioned steps and aims to: 1) promote understanding about humans' activities impacts on natural resources and 2) promote awareness about the humanity's future dependence upon the adoption of more conscious and responsible attitudes and behaviours towards energy sources use.

This didactical resource integrates several software typologies (such as modelling and simulation), with didactical activities specified in teacher exploration guidelines. This courseware is constituted by: i) an educational software (CD-ROM and *on line* versions, *demo* version in http://sere.ludomedia.pt/); ii) teacher exploration guides; iii) student registers and iii) user technical guides.

The online software version enables interaction with a social networking platform (Moodle), where users (students and teachers) can access a scientific glossary and database, specifically created to provide access to multiple documents, videos, and others documents. This platform was developed in order to allow user's communication and collaboration among each other and with the multidisciplinary team.

Teacher exploration guidelines suggest several possible activities to work with the courseware and are structured as follows: i) presentation and educational purpose; ii) exploration context and, iii) exploration methodology. These guidelines were developed in order to provide several educational activities leading to science classroom courseware integration.

Courseware Ser$_e$ structure is essentially organized in two interrelated Phases that represent specific problems caused by energy natural resources unconscious use, namely oil and forest.

Figure 1 - Examples of some screens of the *Courseware* Ser$_e$

Phase I main purpose is for students to research various aspects related to oil production and consumption, to point out oil reserves and consumption levels in a world map, and to identify these natural resources uses in diverse daily situations. This energy resource finitude and the impossibility to generalize today's consumption levels to all the planet's inhabitants will raise subsequent problems and the forest use appears as an alternative energy resource (***Phase II***). However, the social and environmental impacts emerging from this energy resource use, as well as forest imprudent management and renewable resource scarcity raise the third question/problem: Which are the alternative future energy sources? (***Phase III***, in development)

In between Phases, the users/students role will consist in information research, selection and organization, having Discussion Forums available, which allow for the sharing of information gathered by each group, but also to a more coherent next Phase, in a contextualized transition process.

To conduct this research and to guide the establishment of the necessary relationships and interactions between population and resource use, 8 characters were created - 6 explorers and 2 team coordinators (**Figure 2**) – that can play different roles throughout the entire situation, particularly escorting each of the groups during the various activities.

Figure 2 – Explorers and team coordinators

3) COURSEWARE SER$_E$ EDUCATIONAL METHODOLOGY

The start of the Courseware use is intended to be through the exploration of a context situation. A *movieclip* was developed relating the human being with the natural resources use. The impact of several natural resources use comes out as an initial problem for the courseware exploration. This is a four minute *movieclip* presented by 2 team coordinators and intents to be the starting point for an inquiry strategy that will motivate 6 “explorers” of the international company to study, from a constructive point of view, the use of natural energy resources.

Starting with this context, the arising problem should emerge from shared reflection between teacher and students, providing students with both the identification of their conceptions and the definition of some questions/problems. These questions/problems will serve the purpose of guidelines for the research, and their joint analysis will allow for a better understanding of the initial problem. Each one of the working groups will be responsible for a question/problem, to which a solution should be devised.

Presentation of content and exploration strategies will be made by reference to each of the Courseware Ser_e Phases, previously identified.

Phase I – Oil
The first step of the Discussion Forum will be the joint construction of a question/problem enabling the understanding not only of oil importance, but also concerning the relationship between oil use possibilities and the world's population access. The question suggested in the teacher guidelines states *What will happen to oil if we use it without thinking?*

This question should allow the formulation of sub-questions, which focus on more specific aspects of the problem. This will facilitate the understanding of several related oil issues understanding. Some of the sub-questions suggested are: *What is oil used for?; Where does oil exist?*; *What are its consumption impacts?* and *What can influence the oil reserves?*

In order to construct answers to each of the referred sub-questions, the teacher can organize students according to each one of the 6 explorers. Each group will have to search, select and organize the required information, available in the software and/or in another information sources (Internet, books…). The constructed results will be presented and discussed in a following stage during the Discussion Forum.

The goals of ***Phase I*** Discussion Forum are, on one hand, to highlight the relations between oil consumption, oil reserves location and consumers number and, on the other hand, to raise the question about the referred interaction: *What will happen to oil if we use it without thinking?*

After this Forum, the information gathered by each group should enable to present the characterization of the current oil situation. According to this, the teacher should lead the students to the identification and separation of conditions that influence the future availability of this resource, namely: oil reserves, developed countries levels of consumption and consumers number. This conditions individualization allows for their co-relation, facilitating the understanding of the combined impact of the consumer's number and the levels of consumption. Thus, from this identification, it is possible to arrange a simulation organized plan based in Goldsworthy and Feasey's planning chard (1997):

i) *What will we modify*? A: consumers number
ii) *What will we maintain*? A: consumption levels
iii) *What will we measure*? A: deposit oil amount
iv)

Simulation use allows for the establishment of relationships between the consumers number and deposit oil amount, when consumption levels are maintained equal to all consumers.

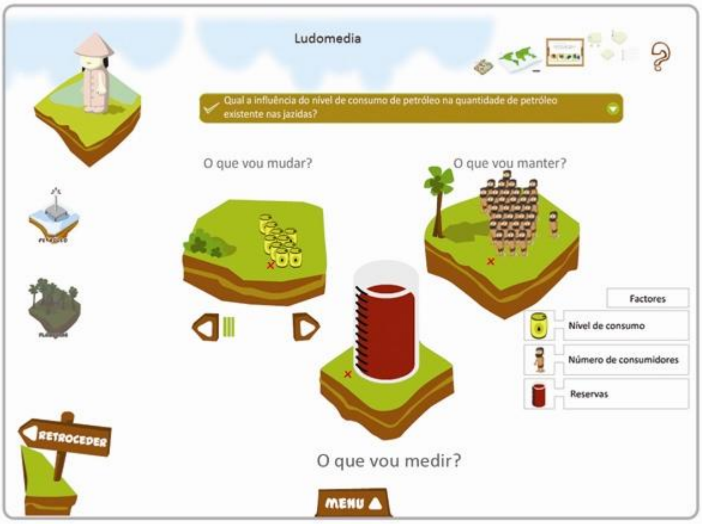

Figure 3 – Oil consumption simulation

Phase II – Forest
This Phase has as several purposes: to promote the understanding of forest diversity; to perceive that forest local use is influenced by population social-economic context; to recognize the forest variety, understand its environmental, social and economic value and to perceive that the forest is a renewable natural resource.

Exploration of Phase I will result in a systematization of information regarding different oil use possibilities and its related multidimensional impacts. The purpose of the new Discussion Forum is to generate shared reflection about oil energy alternatives. At this stage, explorers are required to consider the oil use information gathered so far, and to identify energy alternatives found by the people who can not access oil and take advantage of its several uses. Wood emerges as one of the main alternative energy resources, along with and a new question to debate: *How is forest used by human beings?*

Resembling Phase I, this initial question should allow for the formulation of sub-questions during the Discussion Forum. The suggested sub-questions are: *What is forest used for?*; *Where are the main forests located?* and *Which will be the wood consumption impacts?.*

To answer each one of these sub-questions, the groups, following their respective explorers, return to their original region. There, they will be confronted with new problematic situations whose resolution requires the use of local wooded and non-wooded products.

Phase II Discussion Forum will allow for the characterization the use of products from local forests. Each group of students shares information regarding the characterization of the visited local, enabling the others to "see" another reality. However, the students will also be confronted with the forest depletion possibility, despite it being a renewable natural resource. The question *Which are the future energetic alternatives?* leads to the transition to the next Phase, which is presently being designed by the original team members of this project.

CONCLUSIONS

Courseware Ser$_e$ is the result of a multidisciplinary team work, emerging from combined research, development and practice. For its characteristics, the team considers it a value contribute to ESD. It's a based didactical resource, with several validations. It has several activities variety in continuous development. It's an active citizenship support resource, through the possibility of several competencies development. It has a teacher training programme to support its exploration.

This didactical resource has been subjected to several iterative evaluations (Costa *et al*., 2009; Guerra, 2007; Sá *et al*., 2008), and is the resulting work of the authors expertise and the final users contributions (as well as Science Education experts), allowing to the identification of its shortcomings and to the (re)elaboration of detected fragilities.

Since Courseware Ser_e is based on ESD principles as designed by the UNESCO - didactical issues/questions based in nowadays problems (sustainable development); interdisciplinary perspectives and information and communication technologies integration – it's the team's intention that this didactical resource can serve the purpose of being one valid contribute for the United Nations Education for Sustainable Development Decade.

TEACHING EVOLUTION IN A MULTI-CULTURAL SOCIETY: TEACHERS' CONCERNS AND MANAGEMENT STRATEGIES FOR COPING WITH CONFLICT

Martie Sanders

ABSTRACT

The introduction of evolution as a new topic in the externally-examinable Grade 12 *Life Sciences* curriculum in 2008 in South African schools raised serious concerns amongst teachers about potential controversy between religious beliefs and evolutionary theory. The problem is exacerbated in South Africa, where most schools are multi-cultural in terms of religious beliefs. Semi-structured interviews with 25 teachers after two years of teaching the new topic showed that although many concerns had been allayed as teachers experienced the reality of teaching evolution and developed their subject matter knowledge and pedagogical content knowledge, managing the controversy was not easy. An analysis of management strategies identified approaches which successfully alleviated concerns (of teachers, learners, and parents) but showed that some approaches promoted controversy. Stereotyping teachers and their likely approach to teaching evolution, based on their religious affiliations, was shown to be inappropriate. A model of factors influencing the potential conflicts when teaching evolution can help teachers, teacher educators, and curriculum developers to ensure learners get a fair deal, from the point of view of respecting religious beliefs and in ensuring they are taught the science of evolution fairly.

Keywords: *teaching evolution, managing conflict, multi-cultural religious beliefs*

THE CONTEXT OF THE STUDY

The inclusion of evolution in the new South African school curriculum

A new curriculum introduced incrementally in South African schools from 1998 to 2008, included the implementation of nine new classroom practices (Sanders and Kasalu, 2004) and added several new topics in the various sciences. One new topic introduced into the final year of the senior *Life Sciences* curriculum was evolution, which makes up 25% of the Grade 12 curriculum and the school-leaving examination for *Life Sciences*. Three important reasons are given to support the increasing efforts being made to include evolution in school curricula worldwide. Firstly, evolution provides a framework which allows biologists to understand many of the fundamental principles and processes which explain the living world. As pointed out almost forty years ago by Dobzhansky (1973: 125), insights in biology are so grounded in an understanding of evolutionary theory that *"nothing in biology makes sense except in the light of evolution",* and more recently the National Academy of Sciences (2008, ix) reiterated that "[e]*volutionary biology has been and continues to be the cornerstone of modern sciences*". Secondly, because evolution has increasingly been seen by biologists as a central theory of almost every branch of biology, and applies in many related sciences, evolution provides what biologists consider to be a powerful unifying theme across scientific fields (Clough, 1994). Thirdly, an understanding of evolutionary theory has allowed scientists to devise applications in medical, agricultural, conservation and management, and other fields, and these applications have radically improved the quality of human life in many ways.

Learner-centredness, and its importance when teaching evolution

One of the nine new requirements of the South African school curriculum is that lessons become more learner-centred (Sanders and Kasalu, 2004). Many South African teachers do not fully understand this requirement, focussing only on the idea that learners should be more actively engaged in, and responsible for, the learning process, displacing the teacher as the centre of learning (Sanders and Kasalu, 2004). This is the focus of activity-based learning, another of the nine requirements. Much literature on learner-centredness (e.g. McCombs and Whisler, 1997; Dimmock, 2000) focuses more on teachers knowing about and accommodating learner differences when planning and conducting lessons, so that individual learners are provided with appropriate opportunities for learning and self-development (McCombs and Whisler, 1997). The differences referred to include cultural backgrounds, languages, preferred learning styles, interests, abilities and needs (McCombs and Whisler, 1997). In today's multi-cultural classrooms learners may come from different cultural backgrounds and have differing customs, values and points of view (McCombs and Whisler, 1997). Dimmock (2000) points out that knowledge is culture-bound, and that the ideas considered worthwhile in one community may not be regarded that way by members of a different culture. He explains 'culture' as involving *"patterns of thinking, feeling and acting underpinning the collective programming of mind which distinguishes the members of one group or category of people from another" (*Dimmock (2000, 46). People from different religions can thus be considered to come from different cultures, so guidelines about learner-centredness will also apply to accommodating differences in learners' religious beliefs. However, science teachers need to accommodate cultural differences in ways which do not compromise the scientific integrity of what they teach. This has important implications for the teaching of evolution.

THE PROBLEMS WHICH MOTIVATED THIS STUDY

Multiple problems motivated this study:

1. One problem teachers worldwide face when teaching evolution is the widely held belief that the theory of evolution by natural selection conflicts with the beliefs of many religious groups, in spite of arguments and evidence to the contrary (e.g. Scott, 2000).
2. Great harm is caused by dogmatists at either end of the creationist-science belief-system continuum (see Table 1). Dogmatists disrespect the beliefs and rights of others, insisting that no belief but their own is correct, and often trying to enforce their views on others. In education systems such people are a potential threat to the implementation of learner-centred approaches because they do not respect or accommodate views which conflict with their own.
3. The use of inappropriate strategies for dealing with the potential controversy is a threat to learner-centredness. For example, debates on evolution enforce the notion that there are "right" and "wrong" answers, and that logical arguments followed by voting will reveal the correct answer. Telling "both sides of the story" is also a strategy questioned by those who feel that a science classroom is not the place to discuss religious views, and that doing so means that science is not being given a fair deal.
4. Many South African teachers had expressed a range of concerns about having to teach evolution, almost a fifth of the concerns they listed relating to potential conflicts between evolutionary theory and religious beliefs (Sanders and Ngxola, 2009). These included

concerns about clashes with their own religious beliefs, those of learners, possible conflicts with their school's doctrine, and potential complaints from parents.

5. A fifth problem emerges from literature, which stereotypes people according to their belief systems, and makes generalised statements about how such groups handle the controversy. Such generalizations create false perceptions of the situation in schools, and lead to inappropriate solutions being applied.

AIMS OF THE STUDY

This study had several aims: i) to investigate the various approaches teachers used to deal with the potential controversy when teaching evolution, ii) to see to what extent learner-centred methods are being used which do not infringe on the religious beliefs of certain learners, yet which give science a "fair deal", and iii) to understand and model personal and contextual factors affecting how teachers with firm religious beliefs cope with the potential controversy when teaching evolution.

THE CONCEPTUAL FRAMEWORKS DIRECTING THE RESEARCH

The belief system continuum of Scott (2000) was used to classify the teachers in the study (see Table 1). It places dogmatists at either end of a spectrum, and accommodates along the continuum those with varying degrees of acceptance of religious and scientific viewpoints. Religions originating in the middle East (Christianity, Islam, and Judaism) can be accommodated on this continuum.

Table 1: The creationism-naturalism belief-system continuum of Scott (2000)

<table>
<tr><td rowspan="9">Creationism
↕
Naturalism</td><td>Young-Earth creationists</td><td colspan="2">Interpret religious books literally (the Earth and all living things were created in six 24-hour days, and the earth is 6 to 10 thousand years old). They deny biological descent with modification.</td></tr>
<tr><td rowspan="6">Old-Earth creationists</td><td colspan="2">Accept some scientific evidence (e.g. that the earth is very old, and microevolution) and accommodate some aspects of evolution in various ways.</td></tr>
<tr><td>Gap creationists</td><td>Assume a pre-Adamic creation that was destroyed before Genesis 1:2, when a divine being recreated the world in six days, and created Adam and Eve.</td></tr>
<tr><td>Day-age creationists</td><td>Recognise each of the six days of creation as long periods of time (thousands or millions of years instead of merely 24 hours long).</td></tr>
<tr><td>Progressive creationists</td><td>Accept the fossil record as an accurate representation of history by explaining that a divine being created "kinds" of plants and animals sequentially over a long period of time.</td></tr>
<tr><td>Intelligent design creationists</td><td>Believe complex organisms could not have evolved by chance, and so must have been controlled by an "intelligent designer" – a divine being.</td></tr>
<tr><td colspan="2"></td></tr>
<tr><td>Theistic evolutionists</td><td colspan="2">Accept macro-evolution, but believe it is managed by a divine being.</td></tr>
<tr><td>Materialist evolutionists</td><td colspan="2">Have a non-religious belief system which accepts only scientific explanations for life and its diversity. Some are neutral to religious ideas, while others say that the supernatural does not exist and thus reject the ideas of creationists.</td></tr>
</table>

To direct and interpret the research on how teachers handle the potential controversy Barbour's four-category model, as applied by Anderson (2007) for teaching evolution, was used. A *conflict* strategy applies when teachers perceive religion and evolution as being incompatible belief systems which demand that a choice be made about which to believe. The *independence* approach is used by those who suggest that the two ways of seeing the world (religious and scientific) are very different, and should be taught in different school subjects. The *dialogue* approach promotes the open and critical discussion of conflicting issues. The *integration* approach allows for misconceptions on both sides to be dealt with, allowing the integration of both views as part of lessons. Knowing about *conflict, independence, dialogue* and *integration* strategies (as explained by Barbour, 1997) was helpful in both structuring interview questions and interpreting teachers' answers in a meaningful way in this study.

METHODS

Twenty-five teachers who had attended three- or four-day in-service workshops in 2007 or 2008 to prepare them to teach evolution, and who had expressed concerns (in a written reflective task) about a potential religion/ evolution clash, were interviewed. Table 2 shows the range of religions and denominations represented in the sample. Nine of the teachers were more than just congregation members at their religious institutions, being involved in the organization of a variety of church activities: one was an Anglican church deacon, and another was the wife of a pastor in a charismatic church. Whilst the remaining 16 teachers were involved only as members of a congregation, five of them described themselves as being deeply or strongly religious. I classified the teachers' positions on the belief continuum of Scott (2000) at the time they started teaching evolution (see Figure 1). Just over half (n = 13) were, at that stage, young-Earth creationists who interpreted their religious books literally, and believed all existing species were created in six 24-hour days.

Semi-structured interviews were used to elicit teachers' views, as they allowed for careful preparation of questions to gather the data I needed (so nothing was forgotten during the interview), but provided the flexibility which allowed me to diverge from the interview schedule to explore interesting avenues arising during the interview. All interviews were transcribed verbatim, and analysed using open coding.

Table 2: Details of the sample for the study

Schools (n = 23)	
School type	**Religious orientation of school**
Government schools = 12 Independent Examinations Board private schools = 7 Private religious schools writing the government exams = 4 (2 Muslim, 2 Christian)	Secular = 12 Secular, but with Christian ethos = 3 Jewish = 2 Roman Catholic = 2 Muslim = 2 Fundamentalist Christian = 2

Teachers (n = 25)		
Religion / religious denomination	**Extent of religious involvement**	**Position on belief continuum when they started teaching**
Hindu = 1 Muslim = 2 Jewish = 1 Roman Catholic = 1 Fundamentalist and evangelical Christian churches = 11 (2 Pentecostal , 2 Apostolic, 3 charismatic; 1 Baptist, 3 other) Mainstream protestant = 9 (5 Dutch Reformed, 2 Anglican, 2 Methodist)	Involved in organization of church matters = 9 Member of the congregation = 16 (5 strongly religious)	Young-Earth creationists = 13 Old-Earth creationists = 8 Theistic evolutionists = 3 Naturalists = 0 Could not be classified (Hindu) = 1

RESULTS AND DISCUSSION

Because a number of factors affected how teachers managed the potential controversy, I start the presentation of results by looking at some of the factors which affected how teachers taught evolution, before moving on to examining the strategies they used.

1. Teachers concerns had largely been alleviated

The most notable finding was that teachers' concerns and fears had abated as their subject matter knowledge and their pedagogical content knowledge improved. In many cases fears which had been expressed had never actually materialised, once teachers got to grips with the content.

Fears about conflict between evolutionary theory and the teacher's religious beliefs. Many of the teachers said that once they started reading more about evolution as they prepared to teach it, they realised that that their perception that the two belief systems were in conflict was an erroneous one. In trying to pinpoint reasons for erroneous perceptions, three factors emerged (see quotes in Figure 1):

- Ignorance about what evolutionary theory is about, and what it says. Many teachers said that they themselves had been ignorant, and also that the public in general lacks awareness. They also came to realise that many claims about evolution were based on misconceptions. Several teachers saw that once they knew more about evolution, they were able to interpret their religious books (Bible, Torah or Qur'an) differently, or that they could use their knowledge of the religious books to understand aspects of evolution and where they fitted into the religious scriptures.
- Inappropriately constructed views about evolution. Eighteen teachers had come to realise their religious organization or leaders had never said anything about a conflict between religion and evolution. Teacher #5 explained "*I have never, ever, ever gone to a church service where they have said that evolution was wrong. Never. As I look back now it (the church) is there for spiritual clarification and not for scientific clarification*". A number said that they thought they had constructed this idea personally, based on their knowledge of the creation story, and their scanty and erroneous beliefs about what evolution is about and inferences that "*evolution is bad*", suggesting that they had put the two ideas together ("*we always assumed, as children ...*" T#7). Teacher #5 explained "*it is not actually what you were told at church, but what you were told in other ways …*"

I have always believed, literally, in what the bible says … and, I think because of those beliefs I have never really delved into evolution ... I don't know if it was a sub-conscious blocking, but I feel I was never educated about evolution. And I have never bothered finding out about it because I believed in creationism. I think because of that my knowledge on evolution was so poor. I was so ignorant about evolution … totally ignorant. … But with it coming back into the syllabus, the more I do [the more I] change in my views. (#2)

I have started to discover that there is this huge wealth of information that scientifically explains the creation around us and does not contradict physically what I read in the bible. And I don't have to go changing and manipulating the bible to try and fit it in with evolution theory because they are completely different paradigms and they don't need to be mixed. (#3)

With all the reading that I am doing I don't believe in the true sense that [the bible] is literal … just like any other book it is written by people who are interpreting what was passed down by an oral tradition, before it was written. So I don't believe in the day-for-a-day theory … because the bible contradicts itself. (#9)

And last year was the first time that I actually had to sit down and go into it. And I realised that what I thought … it was actually wrong. It didn't change my belief system, ultimately ... it was just that I was coming, with my belief system, from a point of ignorance. My belief system hasn't changed at all in that way. How I viewed evolution changed. (#5)

And that was mainly because I really lacked information. You know, if you do not know about something, and you just hear this thing, and you think "hey, this is really bad" and you start getting worried. There are some clashes, I agree, but somewhere along the way I realised "you know, science, is not really saying the direct opposite to our beliefs ... our religious beliefs. It's only that science is giving us the in-depth explanation to what we only knew [before]". (#13)

In 2008 Teacher #10 wrote "This will make me think about leaving teaching, and go into another career." By the end of 2009 she said ". I am no longer thinking about changing my career because of evolution. I do not <u>believe</u> in evolution but I <u>accept</u> it as the best scientific explanation for a lot of the observations about fossils, biochemistry, evolutionary changes we can actually see, e.g. how bacteria became resistant to certain medicines. I thought that man came onto earth about 10,000 years ago … but later on … teaching evolution … I have changed my mind. From that day, I don't know how many billions of years have passed, before Adam and Eve appeared on Earth. I believe that God is in control of it. Whatever happens down here I think God won't be cross with you, if you strongly believe in evolution. (#10)

And up until now, that I haven't been confronted with evolution directly, I never realised that there are so many controversies [misconceptions] surrounding it. (#7)

I think that … you know, what I really, really believe is that people don't know what evolution is, and that is why it must be either / or. (#8)

I do believe that a lot of misconceptions come because we are misinformed or because we have too little information concerning evolution (#7)

Figure 6: Interview extracts, revealing teachers' growing knowledge of evolution

- Misconceptions about what their religion's policies about evolution were. Although every teacher had started off believing their religion was against evolution, many had come to realise that their organization had not addressed the matter (as illustrated in the previous bullet). Three teachers had to approach their religious leader for clarification when their institution had not addressed the matter and they wanted to know. Four teachers said their religious leaders avoided the topic, one stating the leader did not seem to know anything about it, another stating that the leader came to her for information about evolution when he heard she had to teach it and had read up on it. Only three of the 25 teachers said their religious leaders had specifically addressed the matter, and were very much against evolution. Many major church groups (e.g. Anglican, Presbyterian, and Roman Catholic) have openly accepted that evolution does not contradict their religious beliefs.

Complaints from the parents: Twenty-two of the teachers said there had been NO complaints from the parents, a number noting that this was completely contrary to their expectations. Two of them, however, said that although there had been no complaints, they were aware that parents were concerned. Several teachers from township schools mentioned that it was not in the culture of black parents to complain or involve themselves in school matters. Only one school had received a complaint, and this was not the expected objection to their child having to learn evolution, but a complaint that the teacher was openly rejecting evolution in class, and was regularly providing creationist explanations for the science he taught.

Complaints from the learners: Seventeen of the teachers said they had no complaints from learners. The interviews suggested this was because of the way these teachers had handled the potential controversy, as explained later. Four teachers noted that learners had initially expressed *concerns* (rather than *objections*) but that these had been dealt with in ways which alleviated the learners' worries. However, four teachers said they had received complaints. One was from a Seventh Day Adventist scholar; one was in a fundamentalist religious school where the school and the teachers were anti-evolution; two were from the same school where both teachers were resistant to teaching evolution, and what they said gave me the impression they were projecting their unhappiness onto the learners.

2. Stereotyping is inappropriate

A second important finding was that stereotyping of teaching approaches, or ways of dealing with controversy, based on religions or on belief systems, leads to inaccurate claims or predictions about how teachers are likely to handle the controversy.

There is a wide range of beliefs within religious denominations:
Several teachers pointed out that statements about evolution expressed by religious leaders were often their personal views, and not the official view of their religious group. Eleven teachers believed their religious group itself did not have a policy. In the Roman Catholic Church official policies have vacillated depending on the views of the current pope, and the two teachers from Roman Catholic schools gave me contradictory statements about whether the church currently accepts evolution (it does). The Jewish teacher told me that in the Jewish faith various sects, as well as different Rabbis, have differing degrees of acceptance of evolution. The same holds true amongst Muslims, traditionally seen as being extremely anti-evolution. However, they have a system of experts (sometimes the muftis) reading up in all modern fields of science, and comparing modern ideas with the scriptures, often accepting emerging scientific ideas which less informed Muslims continue to reject. Not all Muslim teachers know this.

Belief systems of individuals within a faith vary widely:
Judaism, Islam and Christianity, which are all faiths arising in the Middle East, have fundamentally very similar beliefs about the creation of living things. But it became clear that each religion is not a homogenous group of individuals with identical belief systems. Teachers within each of these faiths were situated at different points along the creation-science continuum, from fundamentalists who saw their religious scripture as the divinely inspired and immutable literal truths, to more liberal teachers who accepted that religious writings are transcribed stories based on scientific knowledge of the times, and which should be seen as writings about faith not intended to explain science. One teacher pointed out that fundamentalists tend to be evangelical, trying to convert all others to their faith. Many fundamental Christian groups erroneously believe that anyone who does not take the Bible literally is NOT a Christian.

3. Teachers managed potential conflict in a variety of ways

Meadows *et al.* (2000) explain that conflict cannot be resolved but can be managed. Figure 2 shows how the teachers managed the situation in ways which allowed them to cope with teaching evolution, when originally they had been very concerned about having to do so. Placing of numbers from left to right in the cells reveals the extent of beliefs. Figure 2 clearly illustrates how inappropriate it would be to predict how teachers will teach, based on their religious beliefs.

	Young-Earth creationists	Old-Earth creationists	Theistic evolutionists	Naturalists
conflict	#3 #2 #2			
independence	#24 #1 #17 #13 #14	#12 #4 #15 #7 #11 #19 #16 #2		
dialogue	#10 #5 #22 #20 #25		#8 #9	
integration			#1	

#6, a Hindu (no problem with evolution), difficult to classify on the belief system continuum, is omitted

Figure 2: Teachers' belief systems, and the strategies they used to manage potential conflict

Conflict:
People in this category see religion and evolution as being incompatible belief systems, forcing a choice about beliefs, so conflict is inevitable. Three teachers fitted into this category. Teacher 3, by deliberately telling learners that evolution is incorrect, and always providing alternative creationist explanations, caused conflict, which resulted in a complaint from a parent about the teacher's creationist stance. However, Teachers #2 and #23 (who revealed elements of an "independence" management strategy) may not have intended to cause controversy, and probably did so inadvertently. Although they taught evolution as an accepted scientific fact, they told the learners there are two sides to the story *and they must make a choice.* Forcing a choice does not allow for co-existence of beliefs. I also wondered whether some teachers (who I did not categorise here) might be promoting controversy by making their religious views (which did not accommodate evolutionary theory) clear to their classes*. "I gave MY point of view about what I believe in so the kids know where I come from and that I am a Christian and respect my views"* (#10*).* Other teachers disagreed, Teacher #7 explaining *"I keep my personal views out of it, as it can lead to a lot of conflict*".
Independence:

This proved a satisfactory way of resolving the matter for just over half of the teachers (n = 13), who suggested that the two ways of seeing the world (religious and scientific) are very different and serve different purposes, and should be taught as different subjects. One teacher explained "*I try to stay away from religion, because I believe, you know, that religion can cause a war. And I try to avoid any conflict in my class".* These 13 teachers stuck to teaching only science, telling learners it was in the syllabus and had to be learned for the exam. Teacher #7 explained "*So I definitely work from a scientific point of view. If I stick to the facts I think that will cancel out a lot of problems, problem areas, and possible unnecessary questions, and even arguments. If I say 'listen, guys, let's keep religion out of this. Let's stick to the facts of what's been discovered', I think I am covered, in many ways. That's what biology and science is about".* These teachers reassured learners that learning about scientists' ideas about evolution should not affect their belief system, and this enabled them and their learners to cope. "*Nobody is out to prove God wrong. It's not about God. It's not about religion. Let's keep that out of this*" (T#7).

Dialogue:
This approach promotes the open and critical discussion of conflicting issues, looking at similarities and differences. Seven teachers were classified as having used this approach. Three of them used the footprint activity from the National Academy of Sciences (1998) [showing how factual evidence can be interpreted in different ways] to initiate the dialogue. "*You know that exercise you gave us with the footprints? We started off with that. And I built on the concepts that they need to understand that some things we can prove and other things we can't – we have to infer from the information that we have got. And that, for them, was fabulous. Then they had to realise that what they thought and what actually happened were two different things, and I think that that actually opened their minds up a bit to what was ahead".(*T#5). Teacher #20 explained *"And then I took them on a journey that … to discuss one's theories is not a bad thing … to realise that we are not all going to see it from the same point of view".* These teachers initiated dialogue at the start of the section on evolution, pointing out that it is quite possible to have different interpretations of scientific evidence. Although they were open to answering questions about religious views during the rest of the course, they focussed on teaching the science for the rest of the topic.

Several teachers had taken pre-emptive steps to allay possible concerns beyond the classroom, either sending out a letter to parents clarifying what would happen, and how they would teach evolution, or addressing parents at a parents' evening meeting and inviting discussion afterwards. However, one teacher said their township school had tried to involve parents by calling a meeting about the teaching of evolution and had experienced great resistance which they were unable to overcome in the short time available.

Integration:
This approach allows for misconceptions on both sides to be dealt with as an integral part of biology lessons. Although this would seem an obvious management strategy for teachers with theistic evolutionist beliefs, only one teacher successfully used this approach. She started by getting learners to identify where they stood on the belief-system continuum. *"I was told about how belief systems can be a barrier to learning, and that is why I do it as one of the first talks, because if somebody is going to start talking about something you don't believe in you put up a barrier…. and you won't engage at all."* Consequently she said *"I try to help people see that there are a whole lot of different positions so that they can try and discover that it isn't just the two fundamentalists' opposites of the spectrum, and to discover that there is middle ground and that there might be intellectual integrity in some of the middle ground."* (T#1).She continued to address both religious and scientific issues as they arose, when she taught evolution.

4. Is everyone getting a "fair deal"?

Are learners getting a fair deal?
Most teachers were unaware that learner-centredness is about accommodating learners' belief systems, or how this is done best. Nine said they did not consider the learners belief systems at all. However, all those using an "independence" approach, because of their own religious concerns, intuitively reassured the learners that whilst teaching evolution there was no intention to change what they believed. Although all but two of the schools (even the denominational ones) had learners from a range of different religions, there was a tendency for teachers to use their own belief system, and that of the majority of their students, as the norm. This was Christianity in the majority of cases. For example, Teacher #2 said she DID deal with other belief systems, but these turned out to be the three Christian systems shown in Table 1.

Reasons the nine teachers gave for not trying to use a learner-centred approach (i.e. accommodating religious differences) included a lack of time and the need to cover the syllabus, large classes, trying to cope with the basics of teaching evolution for the first time, not knowing what the learners' beliefs were, difficulty in designing learner-centred lessons, and not wanting to deal with belief systems as it would cause controversy.
Is science getting a fair deal?

Three potential problems were identified. Firstly, many teachers were not devoting 25% of their teaching time to teaching evolution, as would be expected for a topic making up 25% of the marks. Time spent ranged from just eight hours to 32 hours (four teachers), many teachers spending about 14 hours on it. Secondly, although it is important to deal with potential conflict with religious beliefs, it would be unfair to science to devote too much time to religious aspects. Teacher #3 gave an alternative creationist explanation for every aspect of science he taught. Teacher #20 was immensely successful in dealing with potential controversy, but spent about a week doing so. Thirdly, a number of teachers were not giving science a fair deal because they openly revealed their scepticism about evolution. Seven teachers strongly believed teachers should tell learners what they themselves believe, while seven adamantly said they should not, because this unfairly biases learners against science. Ten teachers taught evolution as an unproven theory (in the everyday sense of the word), some incorrectly saying it was not backed by evidence, or evidence was incomplete.

CONCLUDING REMARKS

Helping teachers to deal with concerns about the potential conflict between religious beliefs and evolutionary theory requires that factors impacting on potential controversy be identified. Figure 3 summarises factors identified during this research. The "internal" factors refer to factors within the teachers, central in the model as teachers lie at the heart of all successful educational endeavours. Four categories of internal (personal) factors impact on how they deal with the controversy: their *beliefs* (including their religious belief system, their beliefs about whether it conflicts with evolutionary theory, and their beliefs about how the matter can and should be dealt with); their *pedagogical content knowledge* (including how to deal with conflict, knowledge of typical misconceptions about evolution, and how to make the teaching of evolution learner-centred); their *knowledge* (of both evolutionary theory and their own religion and its policies regarding the teaching of evolution); and their *practices* (i.e. how they actually apply their PCK effectively in the classroom).

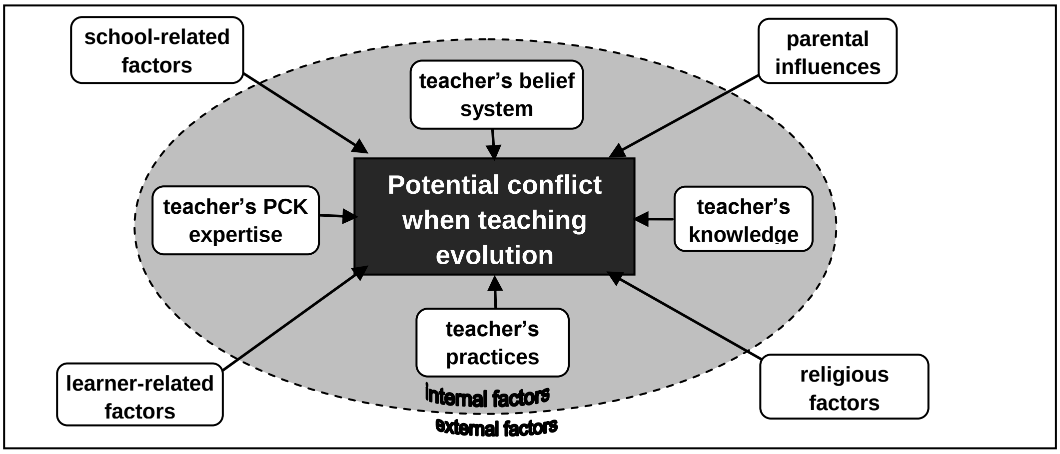

Figure 3: Model of factors affecting how teachers deal with potential controversy when teaching evolution

The "external" factors are those which lie outside the control of the teacher. Four categories of factors were identified in this study: *school-related factors* (school policy on the teaching of evolution, the religious ethos of the school, the heterogeneity of the student body in terms of cultures and religions); *religious factors* (whether the teacher's religious institution has a policy regarding evolution, the impact of the religious leader's personal views); *parental factors* (parents' knowledge, beliefs, attitudes and behaviours regarding evolution, and possible misconceptions they may have regarding the topic); *learner-factors* (similar to those for parents).

The factors identified in this model can place teacher educators and curriculum developers in a more informed position to help teachers cope, by identifying factors which cause controversy, as well as ways of managing it. Although the "external" factors are often beyond the control of teachers, they can be taught to minimize and control such factors, rather than be expected to eliminate them altogether. The "internal" factors are more amenable to control by teachers, once teachers know about them. Some of the strategies used by teachers in this study suggest ways in which potential conflicts can be minimized.

ABSTRACT

We studied teachers' difficulties to implement experimental activities in the classroom as a means to a STS approach to physics classes. Data came from teachers' accounts during a professional development program. Our results showed difficulties in maintaining dialogue with the students, when the explanations attempted by them are different from the scientific one; lack of scientific knowledge, by the teacher, deep enough to deal with experimental situations and improvise explanations if unpredicted effects happen; inability to manage experimental apparatus; contrivance to fully control class timing by diminishing students' possibilities to manipulate the device; and clumsiness in orienting the learning process. We conclude that questions related to operating with didactic experiments are at the core of the difficulty to adopt a STS approach to physics teaching. Professional development programs should privilege experimental activities and stimulate their presence in the classrooms, supporting and accompanying teachers as to deal with these difficulties encountered.

Keywords: *Teacher professional development, experimental activities in the classroom.*

INTRODUCTION

The life of any citizen of the contemporary world cannot avoid involvement with technology, much as to comprehend it as to incorporate it in everyday life, benefiting from the facilities and comfort that it brings. Moreover, the use of technology and its development does not come without a social and environmental responsibility, which must also be adequately understood and assumed by thoughtful citizens.

Scientific education is the main formal vehicle of this knowledge and presumes competent teachers for the task (IRWIN, 1998). These must be prepared to face immediate questions of reality, with STS approach, being able to construct with students a culture which appraises the achievements of technology as well as assumes responsibility for their utilization. The questions which apply always have a global and interdisciplinary character, but also demand depth and rigor in dealing with the specific contents.

Paulo Freire (2004, p.83) stated that "what we cannot do, as imaginative, curious beings, is to cease to learn and to seek, to investigate the 'why' of things". In science classes, the STS approach is one of the ways to make learning more meaningful and useful, concerning the needs of a citizen.

A citizen does not act according to a predetermined order, but has autonomy to deal with the possibilities given, assuming responsibility for the future.

> *"I like to be a man, to be human, because I know that my passage through the world is not predetermined; that my destiny is not given, but is something that needs to be done and of whose responsibility I cannot renounce. I like to be human because the History in which I make myself with the others and in which I take part in building is a time of possibilities and not of determinism." (Freire, 2000, p.58, our translation.)*

An approach that connects the discipline taught to the development of a citizen wants to take into account a more open production, not based on a recipe or on something which has been rigidly oriented. In science also, the citizen-being-formed needs to exercise the ability of thinking and constructing, then re-thinking and re-constructing while learning and re-elaborating knowledge.

There is a diversity of ways in which a STS lesson plan is understood, as, for instance, presented by Aikenhead (1992). Santos (2001a) classified them according to greater prominence of aspects of science, of technology, or of society. While in the last one, emphasis is driven from scientific concepts into analysis of social issues, the first two necessarily include a practical knowledge, not only to understand and create technological devices, but also to understand science as a human construction.

Therefore, in these views, experimentation makes a substantial part of the course plans.

One of the ways to connect science with technology in science classes is to relate concepts being learned with devices that can perform a certain task (SANTOS, 2001b). This is easily done with the help of experiments, which allow the construction of a concept to occur through empirical observation and manipulation. In electromagnetism, for instance, experimenting with simple electric circuits can lead to an understanding of both devices as lamps and the concept of electrical current; constructing a simple electric motor is very helpful for the comprehension of motors in general as well as of electromagnetic induction; and building an electromagnet suits for generation of magnetism by an electrical current and interprets many devices of the kind in everyday life. While developing models to explain all these phenomena, the student also re-lives some of the ways in which the science edifice is built.

The importance of experimentation in science classes as a means to science learning is shared by researchers in the area, as well as the many obstacles to effectively insert it in science curriculum (for instance, as synthesized by Pena & Ribeiro Filho, 2006). The importance of experimentation within a STS approach to science requires, from the teacher, more than only a good knowledge of science, as it involves articulation with technology and social issues. How attainable is this is in Brazilian present context?

RATIONALE

The use of experimentation for science teaching is widely researched, but in Brazil rarely implemented in secondary schools, in spite of many courses and workshops on this theme constantly offered to teachers. Why not? Answers may be complex and lie in more than one aspect. We here seek to analyze aspects surrounding teachers' education.

The objective of this paper is, hence, to disclose some of the possible difficulties encountered by teachers who participate in a professional development (PD) program, when they intend to plan experimental activities to teach physics at high school level. From experiments proposed to participants by the PD program, we analyzed teachers' evolution into incorporating in their class plans some kind of experimentation or device-building with students – always linked to a physics content being taught and that can be related to technological and social aspects and to the personal development of the learner as a citizen.

DATA PRODUCTION AND METHODS

The PD program we have accompanied for this research has a format of a continuous formation which accompanies teachers along the school year. It works mainly based on teachers' course plan, helping them to enhance or modify it according to feedback brought from classroom, of students' learning and difficulties. As the program discusses each teacher's planning individually, for cohesion purposes each year or semester the program focuses on one theme (as, for instance, electromagnetism or optics), and participating teachers must be teaching that theme in the period.

The program consists of 13 participant teachers and one experienced tutor, as well as 2 participant researchers. The teachers are from different schools and have from 3 to 20 years of teaching experience.

The routine of the program works in the following way – as the teacher joins the program, s/he is invited to present a course plan for the theme in focus, which s/he intends to use for his classes. As part of the normal chores of the program meetings, the tutor (an experienced University professor) discusses this course plan – individually, with each participant teacher, but in the presence of all the group. Eventually, teachers will have similar course plans, so the discussion with one may be of use for others. As teachers give their classes, according to their lesson plans, they bring the results to the meetings, which are also analyzed and discussed. With this procedure, the tutor can evaluate the teachers' needs to improve their course plans and students' learning, and provide specific activities to address them.

The meetings occur on a weekly basis and last six hours. In the first three hours, participants are discussing their lessons and plans with the tutor. Then the tutor gives them a task (such as to perform an experiment, study a topic of Physics or discuss someone's course plan) that they will perform by themselves during the next three hours. The two participant researchers act as monitors and assist the teachers in this second part.

The data presented here reveal the difficulties faced by each teacher. It was obtained through audio recordings in the PD program, while teachers discussed with the tutor and among themselves the evolution of their classes. Information is always referent to lessons in which experimental activities were to be carried out by the students. In the PD program, these experiments had been worked with and prepared in maximum detail to be included in the lesson plan. Also the course plans were being discussed all through the program and the participant teachers had opportunity to perform the experiments more than once and clarify possible doubts. The program considers that the process the teacher goes through can be at least partly transposed to the classroom.

Analysis was hence done from teachers' accounts during the PD program meetings. These accounts are contextualized in classes teachers have given and in parts of the course plans they're elaborating or re-elaborating (at the time of the accounts).

RESULTS

We present below the main obstacles encountered by teachers from the PD program we've studied, while they were taking experimental activities to their classrooms.

1. HANDLING EXPERIMENTAL APPARATUS

As simple or complicated an experimental activity designed for basic school may be, teachers common skills are more developed in verbal communication and do not generally include managing and teaching with experimental apparatus. This can be a challenge, even when the activity consists only of observation and analysis of materials. The teacher quoted below tried to repeat an activity – analyzing the internal parts of the bulb – at home before taking it to class, and explained why he, then, didn't take it:

> *"I got the bulb to see if **I** could see these connections. Then I couldn't. In any case, I'm not saying that this activity is not nice, I think it's nice, because it stimulates the student to try to find it out…"*

In this other instance, the teacher still has a very standardized idea about the device she asked students to build as homework – a compass – and the student brings another situation which she leaves aside.

> *Teacher – So I told them, 'you take a magnet, pass on the needle, put the cork…'*
> *Tutor – And why not use the magnet directly?*
> *Teacher – Why not use the magnet? Ah, there was a student who did this today. He got the magnet, put in the water, it sank! [laughs]*
> *Tutor – And then he got it out of there and did what? Got it out and put it away in his pocket.*
> *Teacher – Yes, then it is not possible, you see…*

This dialogue extract shows a second degree difficulty, as explanations involved a content that was out of the limits of the theme magnetism, which was in focus. The idea of *floatation* should be brought.

2. WORKING WITH SURPRISING IDEAS OF THE LEARNER

Interpreting phenomena and building models is an essential part of a course plan when one is concerned with learning science as a human construct. When experimenting is performed by teachers to construct scientific knowledge, it allows for different modeling possibilities.

To the students this is equally valid. Obstacles may arise when the teacher doesn't know what to do with student models that may be different from scientific ones. The process experienced by the teacher in the program was not sufficient to guarantee his/her ability in manipulating with the phenomenon, that could be directed to the objectives desired.

In the following account, the teacher allows for students to model the phenomenon from an experimental activity; however he doesn't open space to the random labor of the student because he'd already had an expectation. So, after the students give their hypotheses on how the circuit works to light the bulb, the teacher pushes aside the ones different from what he had expected –

> *"So this issue of the two energies, it appeared, but I kind of directed it, when I put it on the blackboard."*

This represents a situation in which the student is prevented to manifest his ideas because prevented to actually experiment, try situations, seek new possibilities.

For this to happen, the teacher must also experience the "rights and wrongs" while building an apparatus, to also seek, construct, adapt materials and be creative in new proposals. This is what will enable the teacher conduct his students to develop personally. The teacher must have experienced surprise situations, so s/he can admit that students will come up with novelties.

Dialogue is also interrupted depending on the position and function that an experimental activity assumes in the course plan. In some cases, the experimental activity is performed only to "*prove right*" a scientific concept, leaving little space for investigation and none for modeling. In other cases, a very complex experimental device is taken to classroom before students have elements to understand it. The teacher quoted below included the Wimshurst machine in his course plan as an introductory activity in electricity, with intentions stated as –

> *I do not expect very detailed answers, nor the principles of functioning, but only to introduce electricity – I want them to say, "it has to do with electricity, Mister" (…) The [Wimshurst] machine comes more to play, to receive an electrical shock; what they like the most is the shock. Then I want to direct this into studying the electrical current.*

In this situation, dialogue might happen, but not connecting science and technology, for science is not understood and therefore, technology is seen as *magic effects from a black box*. The teacher's account allows us to detect the conception he has of the meaning of experimental work and its possibilities for construction of knowledge.

3. IDENTIFYING CONCEPTUAL ELEMENTS IN AN EMPIRICAL SITUATION

When an experimental activity is suggested by the PD program, the teachers have an opportunity to perform it in the program (analyzing concepts involved) before taking it to classroom. Nevertheless, teachers may be afraid of the experiment "going wrong", *i.e.* of effects being different from the ones planned. They would have to explain something they fear not being able to – teachers fear making mistakes.

Teachers' not being fully aware of the science present in the phenomenon is often masked by their accounts saying that *students* will have comprehension difficulties, as in the following instance:

> *"[last class] I started the voltage concept. But instead of… The [Daniell] battery I didn't do with them. I didn't have the courage yet. It's so complex, the effects… I don't think they'll understand all that. (…) I don't know much of all that chemistry either."*

This may not be a simple lack of knowledge. The teacher may know the concept, but the form in which it will appear in the experiment cannot always be controlled. A very common occurrence is when the teacher is trying to teach a concept and therefore aims too directly at this objective that he loses other nuances of that content, in other forms it may appear in the experiment. This will certainly occur and the teacher fears not being able to identify such occurrences as part of the objective, or as a part of the scientific model that explains the phenomenon.

4. ALLOWING TIME FOR LEARNING

Teachers wish to fully control the timing of the lesson and fear putting an experiment in the hands of students, for this shall lessen that control. When planning an experiment in which students can manipulate, teachers look for *plug&play* kits, which will have almost every part ready so that students have a minimum effort to make it work and teacher will be in maximum control. Also these almost-ready kits lessen the possibilities for the happening of unexpected effects. On the other hand, they also exceedingly limit students exploring and learning.

> *"But instead of taking only the battery and the bulb, and the cables, I got this kit, that has these connectors, and even the bulb can be adjusted into one of them, and the battery; and so the students had only to plug them together. I thought it would be easier for them."*

The teacher takes an almost ready apparatus, leaving little space for action and experimentation. He wants to quickly arrive to the results and with this prevents that the construction process develops.

Another account reveals that the teacher perceived there was more to be explored by the activity worked with. In an experiment of electrolysis of water, she took the experimental materials for the students to manipulate, but had a very directive way of conducting the lesson. After analyzing students' feedback at the PD program, she comments,

> *"I wanted to give an explanation first, but then we didn't have time to… I mean, we had time for what I had planned, but I will take it again, because I saw it was not well worked with."*

The teacher realized that she did now allow enough time for the students to explore all the possibilities of the device, so she took it again to classroom. The teachers become aware that the learner also needs to spend time, as they themselves have done while exploring the activity in the program.

5. CONDUCTING LEARNING

Classroom management in an experimenting class is different from lecture classes, and teachers feel clumsy in orienting the learning process. In a lecture-type class, the teacher can simply expound the content that he has already constructed and previously organized, according to his vision of physics in that situation. In an experimental class, the teacher is forced to relate with reality and so the sequence might have to become more flexible.

In the following extract, the teacher was disturbed with the incapacity of the students in drawing what they had performed in the experiment. The context was building a simple electric circuit to light a bulb.

> *"…Then they noticed that the contact points are all metal. So, but for me this thing is sort of… I am not very much in control of what I'm doing, I'm putting the things, but when I'll explain how it works, sometimes…/ For example, what I did last class – I drew the battery [on the blackboard], drew the bulb and [asked them to draw the cables connecting them]. I saw that many students, even after having done this experiment, made that wrong drawing, of putting [the cables] in only one pole of the bulb!"*

By the reticent speech of the teacher, we can infer he doesn't know what to do in these classes and can't even put the problem objectively in the PD program. In fact he didn't realize that the problem could be in the manipulation itself, in the time designed to the task, and in the attention to the ideas exposed by the students while working to build the device, what would have caused the knowledge construction to be not as correct, or as rigorous as he had expected. As an immediate reaction, the teacher attributes the failure to the *activity being of an experimental kind*, not to the conditions for an effective construction of knowledge to occur.

The quote below refers to a teacher who is trying to understand how to conduct students into analyzing the electrical current and voltage in parallel circuits. He wants to introduce the mathematical equations of equivalent resistance and expresses what he figures out is the difference between his "normal" lecture classes and the new conducting ways he's learning –

> *"So, because in the normal way, in normal classes we depart from there [equations] to here [circuits], then I end up concluding for them that the equivalent resistance is lower in the parallel circuit and greater in the series. So with these activities, it will be the opposite.*

CONCLUSIONS

Although the PD program may work more deeply with some of the obstacles, others depend on the teachers effectively being courageous and reinventing class management abilities while attempting to insert an experimental activity in their lesson plans. In other words, practice is indispensable. As well as, to the student, empirical manipulation is in itself a rich source of learning, discourse and discussions are not sufficient to produce incorporation of new teaching strategies in a PD program. A variety of different forms of practice are required to provide teachers with the confidence necessary – and some of them must be commenced by the teacher.

> *Very* few *people are aware that in* each *of our fingers, located somewhere between the first phalange, the mesophalange and the metaphalange, there is a tiny* brain*. (Saramago, 2003, p. 64)*

There is a lot of knowledge generated through experience. Saramago (*ibid*) also compared the knowledge of the *head's brain* with that of the hands and fingers – the first being general and diffuse intentions of what must be done. A teacher from the PD program stated it as –

> *"In reality, the knowledge you have is always a little superficial, because only when you are there, manipulating the things… there will be things that can only appear in the experiment."*

We have presented obstacles faced by teachers in their classes, in categories which attend to the purpose of structuring and organizing data. However, the reasons for a teacher not to take an experimental material to classroom frequently conjugate more than one category. In the theme optics and waves, for instance, the ripple tank was used by the teachers during one entire semester within the PD program, to produce and study various effects; each participant had even the task of building a ripple tank. Yet, it was taken to classroom by very few. If, in the beginning, reason was that they felt insecure about handling it, then, conducting learning difficulties became more evident, as in –

> *"There are many students and I wouldn't know how I would manage to show the effects to them all. I think it would create a mess, because I'd have to make a demonstration…"*

Overall, teachers are themselves afraid of manipulating experimental devices. In the group we've studied, we observed that as long as the proposal included such simple devices as an electric circuit, teachers could take it to their students, with all the difficulties seen above, after a hard work in the program. But as devices would become more elaborated (as the Daniell battery or the electric motor), fear increased.

With all work done in the PD program, teachers still faced difficulties to handle situations with the students, what we attribute to lack of sufficient manipulation – in terms of investigating empirical situations and experimental apparatus, solving problems by constructing new devices, and then finding new problems…

To avoid surprises or to fully control timing and more effectively concentrate on the phenomenon being taught, the teacher takes almost-ready devices that he thinks will make the process easier for the student. In doing this, though, he limits manipulation and possibilities of verifying other materials or other hypotheses, and examining the situation from different angles. The conception of teaching and learning revealed by this is inconsistent with the broader objectives of forming and developing citizens.

In order to allow space for students, the teacher needs to develop an attitude that *he will find novelties*. Freire, in Pedagogy of Hope (2004, p.123), tells a story of a Swiss teacher who tore a child's drawing because the cat he had drawn could not possibly exist in those colors. Talking to the teacher, the kid's parent discovered that the teacher herself was terrified of situations in which she was demanded to create or decide.

Physics teachers have to find in experimental activities a source of exploration of both phenomena and concepts, of learning and inventing. Within the conception that teachers usually have of an experiment and are capable to take to class (because they were taught in that same way), a more profound form of construction of knowledge is barred, for: *i)* they want to keep the experimental activity within a step-by-step set of procedures – a recipe – and *ii)* they wish to maintain a content organization that keeps physics themes separated – as in the example where floatation could not be thought of in magnetism classes. But technology – and reality – do not see such division.

Allowing the students to manipulate without a recipe is very dangerous if one wishes to maintain a rigid and linear course, with nothing out of the script and no place for the unknown. Many teacher education programs seem to express the same fear, and therefore, exhibit similar conduct.

We believe that questions related to operating with didactic experiments are in the core of the difficulty to adopt a STS approach to physics teaching. Hence, it seems that professional development programs (as well as initial formation programs) should privilege experimental activities and stimulate their presence in the classrooms, without failing to address teachers' obstacles to their implementation, as the ones showed here.

ABSTRACT

This paper presents the results of research into a nationally funded project, 'Socially Responsible Science', in which science teachers developed and implemented *ethical dilemma story pedagogy* in their own classrooms. The research focused on (i) science teachers' success in creating a values learning classroom environment and (ii) the impact on student learning, in particular their development of collaborative problem solving, evidence-based decision making, critical thinking and critical reflection. The research methodology consisted of ethnographic participant classroom observations and interviewing as well as the implementation of a specifically designed questionnaire - the Values Learning Environment Survey (VLES) – to obtain measures of students' perceptions of key aspects of their learning activities. The research results identify key factors shaping teachers' differential design and implementation of dilemma story pedagogy and students' differential engagement in values learning.

Keywords: *socially responsible science education; dilemma story pedagogy; values learning; scientific literacy.*

INTRODUCTION

In this paper we present the results of research into a nationally funded project, 'Socially Responsible Science (SRS)', designed to enable science teachers to better prepare young people for our crisis-ridden world by developing their critical scientific literacy skills. As Hodson (2008) explains, there is growing interest in a 'universal critical scientific literacy' that equips all students with "the capacity and commitment to take appropriate, responsible and effective action on matters of social, economic, environmental and moral-ethical concern" (p. 2). As facilitators of the project we drew on our commitment to a transformative science education that better prepares students to participate as informed members of society and future decision-makers in the science-informed discourse about pressing global issues such as climate change and environmental sustainability. We drew also on our earlier research, based on the pedagogical use of stories for moral development (Vitz, 1990), that had demonstrated the efficacy of *ethical dilemma story pedagogy* for engaging students in values learning in the science classroom. In that study teachers had used specially prepared ethical dilemma stories to engage students in critical reflective discourse and collaborative decision-making on the ethical implications of science and its uses (Settelmaier, 2003, 2009). This innovative approach to socially responsible science education addresses the National Framework for Values Education in Australian Schools and the National Goals for Schooling in the Twenty-First Century, as outlined in the Adelaide Declaration (1999), which argue that Australia's future depends on a solid foundation for young Australians' intellectual, physical, social, moral, spiritual and aesthetic development (Department of Education, Science & Training, 2005). This approach also contributes to the recent call to 're-imagine' science education as an exciting, authentic, investigative and meaningful experience for all students (Tytler, 2007). In this respect, a good ethical dilemma teaching story – like all classic moral dilemmas - has no final solution, thus allowing for prolonged thinking, reflection and learning. Content knowledge – chemistry, biology, physics, mathematics concepts and skills - is essential in order to understand and to find solutions to the ethical dilemmas embedded in the stories. Thus dilemma story pedagogy does not aim at replacing content-based science education but rather aims to enhance its quality and relevance to modern day students by 'adding value' to their learning. During the project, science teachers participated in professional development workshops designed to familiarise them with ethical dilemma story pedagogy and to write ethical dilemma stories relevant to their specific curriculum contexts, to their students, and to local community issues and concerns. The ethical dilemma stories, together with project teachers' implementation notes, are available to science teachers worldwide on the project website: www.dilemmas.net.au. This paper focuses on selected teachers' implementation of ethical dilemma stories in their science classes.

METHODOLOGY

Our research into the teachers' classroom implementation of their ethical dilemma teaching stories was shaped by a multi-paradigmatic research design perspective (Taylor, Settelmaier & Luitel, in press). We employed a mixed-methods approach which included (a) ethnographic methods of participant observation and interviewing and (b) administration of the Values Learning Environment Survey (VLES). The original participants included 8 metropolitan government secondary schools, 22 science teachers, 65 secondary students in Years 9-12 and 17 postgraduate students. This paper focuses on four of the teachers - two female and two male. The research received ethics clearance by the Curtin University Ethics Committee. Participants' identities and schools' names are protected through the use of pseudonyms.

Ethnographic Component of the Research

The ethnographic component of the study involved participant observation of classroom teaching and interviewing of teachers and students. This part of the study formed the basis for the third author's Bachelor of Education Honours thesis. As a research assistant, Julia spent an extended period of time at each school observing classes conducted by the participating teachers. Elisabeth observed all but one of the four teachers' classes. Julia interviewed five students per class and the class teacher and collected the completed questionnaires after they had been administered by the teachers. Students were chosen for interview on the basis of their involvement (or lack thereof) during class and their gender. The quality standards governing this part of the study were trustworthiness, transferability, credibility and fairness (Guba & Lincoln, 2005). Fairness of representation was established through member checking and giving 'voice' to participants as often as possible.

The Values Learning Environment Survey (VLES)

The quantitative component followed standard learning environment research procedure for optimising reliability and validity (Taylor, Fraser & Fisher, 1997). The VLES questionnaire was administered by the teachers shortly after each dilemma teaching episode, yielding 65 useable student responses. The instrument can be accessed on the project website. The VLES was developed with three specific goals: (a) to promote values learning: the instrument provides teachers of science (and other school subjects) with a clearly articulated framework for establishing a values learning classroom environment; (b) to assess values learning: the instrument provides teachers with a relatively simple method for assessing the quality of students' engagement in values learning; and (c) to monitor values learning: the instrument allows teachers and researchers to trace students' long-term values learning development. We designed the VLES in order to obtain measures of students' and teachers' perceptions of 6 key factors of the classroom learning environment that our earlier research shows (Settelmaier, 2009) are conducive to values learning: *critical self-reflection, empathic communication, critical social thinking, deep engagement, collaborative decision-making, teacher support*. Each of these factors became initially a 7-item scale, later reduced to five. We designed the questionnaire in two versions for measuring perceptions of the learning environment as experienced (a) by students and (b) by teachers. Previous research has established that student achievement is optimal when students perceive a close match between their preferred and actual learning environments (Fraser & Fisher, 1983). We incorporated a five-point Likert-type frequency response scale. For readability purposes on the questionnaire we re-named the scales: 'The Dilemma Story' (*deep engagement*); 'The Teacher' (*teacher support*); 'Learning to Work Together' (*collaborative decision-making*); 'Learning to Listen' (*empathic communication*); 'Learning to Think' (*critical self-reflection*); and 'Learning about Science' (*critical social thinking*). Statistical analysis revealed that the Cronbach alpha coefficients lie in the range of 0.76-0.91, indicating satisfactory internal consistency of all scales.

RESULTS AND DISCUSSION

Our discussion of the results focuses on (a) the differential quality of the teachers' implementation of ethical dilemma story pedagogy in their science classes and (b) the impact on students' learning experiences.

Teachers as Facilitators – The Teachers' View

Here we focus on four teachers in three government senior high schools in metropolitan Perth who implemented dilemma story pedagogy in their classrooms. Both female teachers, Delia and June, taught at the same school, whilst the two male teachers, Jeremy and Ron, taught at different schools. Although they had attended the same professional development workshops, it was only the two female teachers who adhered closely to our intended dilemma story teaching approach: *to read out loud or tell freely a dilemma story to the whole class and to pause from time to time for individual student and small-group reflective learning* *activities*. This approach is designed to enable students to identify deeply with the main character in the story and to make decisions on behalf of the character. Delia dedicated several preceding lessons to teaching specific content to her Year 10 class in preparation for the *Western Swamp Tortoise Dilemma story* (see project website for details). June used the *Climate Change Dilemma story* with her Year 12 class as an introduction to a new topic. In contrast, Ron and Jeremy chose to implement dilemma teaching in a more didactic manner: without using a story-telling approach, they presented their classes with dilemma questions only and instructed students to work directly on the questions. Ron presented a dilemma scenario approach related to the topic of *Reproduction*. Jeremy provided his students with a range of loosely connected questions in relation to the topic of *Genetic Counselling*. Thus, dilemma story teaching was not implemented consistently across the sample.

During interviews both Jeremy and Ron seemed to assume that the SRS approach catered more for the teaching and learning of values education rather than for science education per se, as expressed in Ron's comment, "I would have thought it was much more values than science." June and Delia, on the other hand, expressed a view of science and values as being inseparable. In contrast, all of the interviewed students seemed to think that the focus of the ethical dilemma stories was science. Some seemed uncertain as to the concept of 'values' but most interviewed students reported they had been able to apply their science knowledge when trying to solve the dilemmas. Literature on values education (op cit) states that many teachers avoid engaging with values education as part of their curriculum since the curriculum is 'too crowded'.

We asked the four science teachers how they could see socially responsible science education fit into the mainstream science curriculum. Jeremy explained that it was easier to fit ethical dilemma stories "…into lower school classes rather than upper school classes." This was considered to be particularly the case for classes in which university aspirations were low which Jeremy assumed would be the case with his classes and his school. Ron seemed not convinced that this type of learning was 'legitimate science' and admitted that, "I probably wouldn't have done this if you weren't coming." We were surprised to hear this type of comment from somebody who had been involved voluntarily in the project from day 1 and who had attended all professional development workshops. One might wonder as to what motivated Ron to participate in the first place and to agree to participate in the research component of the project. Given his misgivings about the dilemma learning approach, he seemed genuinely surprised that, "…they [my students] were really engaged. They were much more engaged than they usually are!" Both male science teachers thus seemed to have doubts as to whether this type of learning was science and not just a 'waste of precious time'. This stands in stark contrast to their students' opinions as described later in the paper. While both the female teachers felt they would "…not be teaching the full curriculum if values were not taught in the science classroom" and seemed to feel that, "…ethical dilemma stories would be a useful strategy to achieve this". Delia expressed an interest in conducting an ethical dilemma story prior to a unit of study and then conducting it again at the end of a unit of study to see how scientific knowledge helps students form their values. June described the "…values and science as inseparable". It is interesting to note that the two male teachers apparently thought that this approach catered more for the teaching and learning of values education, while the two female teachers I interviewed seemed to view science and values as inseparable.

Students' Deep Engagement with the Dilemma Learning Experience

Students' deep engagement with dilemma stories and the dilemma learning experience is crucial for the success of this type of pedagogy (Settelmaier, 2009). The results of the ethnographic aspect of the inquiry indicated that students' engagement with the dilemma stories seemed positive, and most interviewees described the experience as 'fun' and as 'different' from usual science classes. As Michaela pointed out, "I thought it was really good." Emma, Lee and Phil also seemed to enjoy the dilemma experience as fun and different: Emma contended that it was "…good to learn about how stuff works and there is more to it than just looking at it". Lee elaborated further that "…it kinda didn't feel like science …but it was good to do something different." Phil described the experience further as, " … it was different from a regular class… 'cause normally it's book work kind of stuff. This was different as it wasn't really to do with the books, it was good." Peta, one of the top students in her class seemed to have been able to combine fun with the application of science knowledge, "…it really did help us apply what we have learned in science… and yes, I could use my science knowledge." Only one student reported not being interested in the topic of 'his' story: his class had been engaged in the *Western Swamp Tortoise Dilemma Story* and he was open about the fact that he wasn't interested since "turtles weren't down his alley". This also confirms one of the outcomes of Elisabeth's doctoral research which was that dilemma story topics must be relevant to the students: if students do not relate to or do not fully understand the dilemma in a story, they cannot engage in the necessary thinking and reflection processes. Students commented on the potential of the dilemma learning experiences to 'get people to think' and to 'wake them up'. Some students, like Sam, apparently experienced the dilemma learning experience as a 'wake-up call', "I know for a lot of people it did kind of …umm …wake them up as to who they would choose." Students, like Chloe, also pointed out the connection to real life, "…it could happen, you know, and you would have to face that dilemma." James seemingly referred to a similar 'link between the classroom and real life' when he stressed the importance of becoming aware of how others think and feel, "…if you don't know…you're not going to care. You're not going to know how that person feels." The link between knowing about others' thinking and feelings and caring about others was also explained by Leah who described the dilemma learning experiences as, "…it does teach people values because if you don't know then you don't really care how the other people think about it."Furthermore, students seemed to suggest that this type of learning be included more often in order to teach about the applicability of science to real life. Matt appeared to confirm the importance of using this type of learning repeatedly by saying, "…yes, [it would be good to do this again] because it makes you think about what you do because when I just learned this stuff it was really fresh in my head…just makes me learn the other stuff again and remember it.…and use it in real situations". Matt's statement is supported by Peta who stated that, "…I think it should be done occasionally to help us understand how science is applied more in the real world……in science, the way we learn it, we don't do as many stimulating activities [in relation] to how we'd apply it to the real world". Even Dan who said he didn't normally much enjoy science confirmed that, "…I think it (should be done) a few times."

Summarising, we can say that students' feedback regarding engagement with the dilemmas was generally positive: students commented on the potential of the dilemma stories to 'get people to think' and to 'wake them up', that it was fun and different from usual science classes. Furthermore, they pointed out the importance of the connection to real life. These qualitative findings are also confirmed by the results of the quantitative analysis whereby nearly two-thirds (65%) of the students indicated the dilemma stories were deeply engaging, relevant to their lives, felt curious about the stories, and were keen to solve the problems in the stories. A third of the group was unsure, with one student disagreeing.

Teacher as Facilitator - The Students' View

The teacher's role as a facilitator, agent provocateur, or devil's advocate is vital within our values learning environment. The teacher is more of a guide than a 'dispenser of values'. Given that science teachers often find themselves in the role of the person who 'has all the knowledge', taking a step back and allowing students to engage actively in their values learning can be a challenge, as expressed by two of the participating teachers in their interviews. However, interviews and observations indicated that teachers seemed to receive mostly positive feedback on their facilitator role, their engagement with the students, and for trying something new and different. Student Leah noticed that apparently, "…he [the teacher] was not really comfortable with the new ways…but he did a good job." Whilst other students, such as Matt, confirmed that their teachers seem to act as facilitators most of the time, "…she always teaches us like that. This time it was just more so…!" Students, like Dan, seemed to appreciate the opportunity to speak up and be heard, "…[He] just listened …[and]…[he] let us express our opinions without telling us we're wrong. Students also noted the unique opportunity for their teacher to learn about his/her students, something that apparently doesn't happen normally, as was expressed by Emma, "…because he has basically learned about us throughout the year but there's still some spots that were vague in our personalities that he knew and through this exercise he could really get a stronger vantage point of our character." It was interesting how important it seemed for students that their teacher knew something about them personally.

Summarising our qualitative findings we can say that teachers received positive student feedback on their facilitator role and their engagement with the students, and positive recognition for trying something new and different. Students also seemed to note a unique opportunity for their teachers to learn about them. Furthermore, students appeared to appreciate the opportunity to speak up and be heard without being interrupted or told off for talking. In addition, these results derived through the ethnographic component of the study have been confirmed by the quantitative results where nearly all (94%) of the students indicated that their teachers facilitated their engagement in dilemma story learning activities by stimulating their thinking, encouraging them to participate and accepting the views of others. Only a very small proportion was unsure and none disagreed.

Collaborative Problem Solving and Evidence-Based Decision-Making

Collaborative decision making involves student groups negotiating a decision and/or a compromise in order to solve a problem as a group. Furthermore, students draw on both their own values and increasingly on evidence provided to them through their science learning to make informed decisions. One of the key issues raised during the ethnographic inquiry was the importance of recognising difference in opinions and values and working with it. Students reported that through the group-work and the discussions they seemed to become more aware of different opinions. For some this didn't seem to cause any problems since, as Vicki put it, “I’m used to people having different opinions.” Some students, on the other hand, reported difficulties in the decision-making process due to conflict which may or not have been resolved, like in Julie’s group’s case, “… there was a little bit of conflict in my group!” I think they both just let it go ‘cause they knew they weren’t going to change either one’s idea. So they decided to just stick with their own [opinion].” It appeared that students in her group rather compromised than tried to convince the other person. Students also indicated that knowing about each other’s different opinions did not necessarily cause them to change their own. “After I had listened to other people’s opinion I got what they were saying but I still stuck with mine.” However, in a different school and class, Simone and David had an argument about their difference of opinion that was not easily resolved through compromise. As Vicki, a student who observed the argument, described the situation in her interview, “…she [Simone] got kind of…didn’t really realise why he was thinking that!” To Vicki it seemed that Simone was keen on convincing David that his opinion wasn’t acceptable. Asked later, Simone admitted that, “…I kinda understand why he did it but I don’t really agree with it!” Apparently Simone was still annoyed about David’s behaviour and she added, “…he did it like to cause a stir! He was just being provocative!” It was interesting that Simone described the incident as “… kind of a friendly argument. We were like discussing it, and I was just getting a little bit angry!”, whilst Vicki seemed to have interpreted the situation as a ‘real’ argument. Simone, on the other hand, didn’t seem to mind, “… sure it was resolved but I was okay with it!”. In any case, watching their argument and listening to what David and Simone had to say apparently caused other students, such as Vicki, to reflect on what was being said and on the reasons for doing so. In yet another group conflict was resolved because, “…we were both really accepting it [the difference in opinion]. We have different backgrounds.” Thus knowing each other well seems to have helped with conflict resolution. One student, Dan, stated that it was okay for him to have his own opinion unless somebody else’s life depended on it. Asked to clarify by the interviewer, he said that, “…then I would like other people’s opinions so I’m not just the one that gets blamed for making the wrong decision.” Some students seemed to realise that whilst others have the right to different opinions they personally could not agree with those views. They stated that they had come to understand that both compromises and maintaining one’s own opinions are necessary as this excerpt from the interview with Emma illustrates: *“…* a few things made me …well, the others and what they said…a few things were a bit worrying!” Julia asked for further clarification, “What worried you?”. Emma explained, “…about other people’s priorities and what they would do… like the whole human life or embryo life or something like that…”, and she added, “… [in my group] we worked out some of it but I didn’t really agree with what they were saying, and they didn’t really agree with what I was saying but between them they agreed!”. Julia asked, “…how did it feel with your friends having different opinions from you?”. Emma admitted that she felt, **“…** alone!”, yet with a smile she added, “…it was good having my own opinion rather than somebody else’s!”

Summarising we can say that some students reported difficulties in the decision-making process due to conflict that remained unresolved whilst others seemed to accept conflict as okay if one was convinced of one’s own standpoint. Conflict resolution and compromise seemed to be helped by knowing each other. Yet some students admitted that knowing about other people’s different opinions did not necessarily cause them to change their own. Some apparently preferred the back-up by other people in the case of life-deciding decisions.

The ethnographic results were confirmed by the quantitative results where just over three-quarters (77%) of the students indicated they had worked well together in trying to resolve the ethical dilemmas embedded in the stories, explaining carefully their ideas to each other and striving to reach agreement. A fifth of the group was unsure, and a small number disagreed or strongly disagreed.

Empathic Communication

Here, the focus is on developing emotional intelligence, empathy, the ability to accept and consider other people and their ideas. Most students reported that they felt their voices were listened to and their opinions accepted as legitimate. Students seemed to appreciate the opportunity to hear about other people's thoughts and opinions, and indicated the importance of knowing what others think and feel in order to care.

Sam summarised well what most interviewees had stated, "…it was kinda fun to hear what other people thought… like from their backgrounds…a lot of people haven't been as experienced as I have. " His statement also seemed to imply that he assumed that others lacked his level of life experience and that maybe in everyday life he doesn't have the opportunity (or interest?) to find out about other people's ideas. Evelyn seemed not only more aware of the differences within her peer-group but also of the importance of knowing about others' thoughts when she stated that, "…everyone has different morals and values though and because not everyone is the same … you got to know that." Lee a student who reportedly had little to no interest in science explained that he appreciated the different style of the dilemma story science lesson, "…we were able to converse and look at each others' ideas and we learned a little bit about each other even though we have known each other for years." His views were confirmed by Dan another student who had claimed that he didn't like science much, "…we got to see different people's ideas and what they think about it." It seemed interesting to us that these two students whose initial interest in science was reportedly low had experienced the social aspect of the dilemma learning as a positive learning experience. One of the high achievers, Megan, thought, "…it was good hearing what other people thought and basically putting my opinions towards them and trying to get them to go my way instead of their way." Her statement was interesting inasmuch as she pointed out that she had to formulate and state her opinion to others in a convincing way which suggests the necessity of deep engagement with the subject matter: one must have understood something in order to try and convince somebody else of its usefulness or validity. Yet arriving at a common understanding apparently was not always easy as Simone explained, "…I know there were a couple of other people that had a bit of a problem trying to choose who they were going to pick [to save in the dilemma story]." She elaborated that she had listened to others' opinions but she also had made sure that,"…[my voice] was heard by the whole class!" With a smile she added, "…my voice was heard!…I got really loud and yelled….the person I got angry at…did hear!" She was referring to the heated discussion she had had with David who had insisted that in the case of their dilemma story (*The Reproduction Dilemma*) it was okay to not save a particular person. At the time of the interview, Simone was apparently still coming to terms with David's argumentation. She reported that she had been thinking about this for quite some time, "…just saving one life would mean only one instead of maybe possibly two or three…That's the only way I can think about it otherwise I don't get it." This seems to indicate that she continued trying to understand Dan's opinion that seemed to stand in stark contrast to her own and that she was still trying to find an explanation for herself.

Summarising, we can say that students reported that they felt their voices were heard and their opinions accepted. All interviewees seemed to appreciate the opportunity to hear about other people's thoughts and opinions and indicated the importance of knowing what others think and feel in order to care. These results confirm the quantitative results where over three-quarters (85%) of students indicated that they had communicated empathically with other students during the dilemma story activities, being open to and respectful of other students' opinions, and relating to other students' feelings. A small number of students were unsure, with only two disagreeing.

Critical Self-Reflection and Critical Thinking

When forced to make a decision students seem to engage in both critical self reflection and critical thinking (Settelmaier, 2009). Critical self reflection occurs when a student reflects on his/her own values in order to solve a problem. Critical thinking, on the other hand, is well documented in the literature as an analytic, systematic problem-solving approach that builds largely on existing knowledge. We asked students how they went about 'decision-making' in a dilemma situation, what processes they engaged in, what values/guidelines (if any) they were drawing on when coming to a conclusion. Some interviewees reported that they did not question their own views or become clearer about what was important to them, whilst others, like Sam, stated that, "…even though we aren't as pressured as being in the real situation, we kind of simulate in our minds from past experiences when we have been under pressure, we've had to make a really tough decision, we can put that together and think about that situation as though we were in that actual position and how we'd assess it." He described well the 'constructivist values-learning process' whereby students draw on previous experiences to find a solution first before constructing new knowledge by adapting and merging old and new knowledge in order to respond to a new situation. Sam's statement was confirmed by Steve who explained that for him the dilemma learning experience had, "…made me think about my own priorities about certain situations and things like that." And Jack argued along a similar train of thought when he said, "…it made me think about the way I [would] go about it all. During the interviews Julia, the research assistant, uncovered an interesting and somewhat unexpected aspect of 'values education' in Australian secondary schools: some students had stated that they did not change or reconsider their values through the dilemma story learning experience, however, further questioning revealed that some of these students were struggling with the concept of 'value', that is, they had no clear concept of the meaning of 'value'. This does not mean they did not have any values, only that they did not know what could be regarded as a value and thus they seemed unaware of the values they were basing their decisions on. A brief excerpt from an interview with Dan illustrates the issue well.

Julia, "Did it make you look at your values a bit more and make you think about it? Dan, "No…well, what do you mean by values?". Julia continued to explain the basic meaning of the term value, when Dan replied, "Well, when you put it that way, yes I did!"

Individual decision-making that involved critical self-reflection was experienced as difficult, challenging and sometimes confronting, as Nicky explained, "…decision making was difficult because we had to state reasons why…". Students had been asked during each of the dilemma question breaks to reflect individually at first before discussing their own ideas with others which apparently pushed some students out of their comfort zone, and some apparently did not like that very much, particularly Evelyn, "…I didn't really like the fact that I had to choose between who I'm going to save first…like messing with people's lives and sort of playing God, so I really didn't like it. I'd like it if I didn't have to make decisions!" Most interviewees, however, agreed that the dilemma-based values learning approach was preparing them for future decision-making, as Lee outlined, "…making decisions…[is] a very useful skill later on." And Emma added that whilst it was, "… frustrating when we had to choose…kind of confronting… I thought it was pretty good and [I] learned that decision making is not always going to be easy. I thought it was good!".

In relation to critical thinking, students reported that they were able to apply their existing knowledge when assessing the dilemma situation. The dilemma approach seemed to help Peta recognise the connection between real-life and science learning, "…it really did help us apply what we have learned in science." Students use their knowledge to critically assess a variety of possible solutions with a view to finding the most viable one.

Summarising, we can say that decision-making was experienced by many students as difficult, challenging and sometimes confronting – pushing some students out of their comfort zone. Some students reported that they did not question their own views and/or become clearer about what was important to them. However, further questioning revealed that some students seemed to be struggling with the basic understanding of the concept of value. Most students seemed to agree that the dilemma-based values learning approach was preparing them for future decision-making. These results were confirmed by the quantitative analysis where three-quarters (75%) of students indicated that the dilemma story learning experience had engaged them in reflecting critically on their own ideas, questioning their own views and becoming clearer about them. A small minority of students was unsure, while only 3 disagreed.

The Relationship between Science, Dilemma Pedagogy and 'Real Life'

We asked students about how they experienced the connection of the dilemma learning experience with science and 'real life'. In other words, could students see a connection between this approach, science and their lives outside of the science classroom? Generally, students seemed able to identify direct connections between the dilemma-based values learning approach and science. They appeared to appreciate the different approach and the opportunity to see how science can be applied in daily life. As Leah reported, "…science helps me… shape my values." And she added that, "… it is good to learn about how stuff works, and [that] there is more to it than just looking at it." Evelyn confirmed Leah's views by saying that, "… yes, [the dilemma learning experience connected well with science] 'cause science is very much...like… it can be problem solving as well as the very basic elements and that sort of thing!" Sam seemed to support Evelyn's and Leah's views by saying, "…I think it had a good connection with science. We thought about it and looked in more depth…we could use our morals and compare it with science." Emma stressed that, "…without science we kinda don't know as much about the world…..how things work, how things communicate with each other and how they work together and what goes with what and what doesn't go with what… then we really get an understanding of ourselves and the way we perceive the world in kind of a more open way." Emma's view seemed to be supported by Lee who seemed to think that, "… science really helps us be open about things. Basically, it had a good connection with science." For Peta the dilemma approach seemed to help clarify the connection between real-life and science learning, "…it really did help us apply what we have learned in science." Yet as Chloe explained, "… it kinda didn't feel like science! … well, it helped me apply it to the real life situation….because the stuff that we learn for school we want it to be relevant to what we want to do or to real life instead of just being work that we're never going to use again!" Chloe's statement about the importance of relevance of students' science learning to real life summarises well the statements of most interviewees. Interestingly she stated that it didn't feel like science maybe indicating that maybe her usual science learning experience lacks this aspect of real life connection or maybe indicating a discrepancy between the way, science is usually being taught to her.

Summarising, we can say that the students seemed to see a clear connection between the dilemma learning experience and science learning through connecting science content to the 'real world'. These results are confirmed by the quantitative analysis where just over three-quarters (77%) of the students indicated that dilemma story learning had helped them become critically aware about the misuse of science, and to learn that misuse or ignorance can have harmful long-term effects on their lives. A small proportion was unsure, while a small number disagreed.

Students' and Teachers' Views - Some Emergent Discrepancies

Almost all students – this includes Year 12 students - seemed to regard SRS as useful and expressed the wish that SRS should be done more often due to its direct relationship to real life. Jeremy, one of the male teachers, however, seemed more concerned about the 'crowdedness of the curriculum' and said it was "…easier to fit ethical dilemma stories into lower school classes rather than upper school classes". He seemed to consider this to be particularly the case for classes in which university aspirations were low. In other words, SRS could be taught to the less capable students whilst he seemed to think that it would not be as useful for the more academic students. Interestingly it was one of his high ability students who spoke out most strongly in favour of the SRS approach – she and another high achiever from Ron's class both seemed to be clear that this type of learning connected science to the 'real world' and confronted them with 'real life' problems where they could apply their scientific knowledge. It appears that Ron and Jeremy viewed SRS primarily as a 'motivation tool' whilst the female teachers stressed they would not be teaching the full curriculum if values were not also taught in the classroom. Delia and June seemed to view ethical dilemma stories as a useful pedagogical strategy to overcome the apparent science-values dichotomy. It was interesting to note that the interviewed students of the male teachers emphasised how much they appreciated the different style of the dilemma lessons, and that their teachers were trying something new even though they appeared uncomfortable. Comparing the opinions of the male teachers and the female teachers in the study, it was interesting to note that the female teachers seemed to assume an inherent connection between science and values thus making it indispensable to teach values as part of science, whilst their two male counterparts seemed much more concerned to cover as much of the prescribed content as possible. It is also interesting that the female teachers' views seem to support and be supported by the majority of the students' views.

CONCLUSIONS

The results of our study indicate that a large majority of students across the sample engaged positively in a socially responsible science classroom learning environment that afforded development of critical scientific literacy skills. In particular, they (a) experienced the dilemma stories as engaging and authentic and as connecting science learning with 'real life' problems, thus making their scientific knowledge applicable; (b) had positive perceptions of their participation in dilemma learning activities which, for some of their teachers, meant an entirely new teaching style whilst, for others, it seemed to have been more of an extension of their usual teaching style; (c) perceived that their teachers had allowed them to express their opinions and 'talk to each other during class'; (d) had engaged empathically with other students in collaborative decision-making, even though sometimes this was not easy due to lack of conflict resolution skills; and (e) had reflected critically on their own ideas and values and found that the learning experience had helped them to become critically aware of the use/applicability of scientific knowledge. Only a small minority of students consistently disagreed that they had experienced any of these aspects of the classroom learning environment. Second, the dilemma teaching approach was implemented inconsistently by teachers. The 2 female teachers closely enacted the role of dilemma learning facilitators whereas the 2 male teachers reverted to more traditional didactic teaching methods. It is interesting that, although the largely positive attitudes of most students and of the female science teachers stand in contrast to the less than favourable attitudes of the two male science teachers, the latter expressed surprise at how well dilemma teaching had worked in their classrooms, especially the positive engagement of their students. These results are consistent with our earlier research (Settelmaier, 2009) and add further evidence to the claim that a socially responsible science education based on ethical dilemma story pedagogy offers a promising means to develop critical scientific literacy skills with which students can engage as socially responsible citizens in informed decision-making about the appropriate use of science for addressing global issues such as climate change and environmental sustainability.

The results suggest that if this type of values learning is to be more widely integrated into science classrooms of the future then transformative professional development is needed that engages teachers in reflecting critically on their (hidden) assumptions about what constitutes legitimate science education and what does not; in particular, on the science-values dichotomy. Because many pre-service science teachers are likely to regard values learning as 'not really' science education, 'value-added' reform of science teacher education programs is needed. Such an approach would emphasise the importance of integrating values learning into the science curriculum, not as a luxury that may be afforded if there is sufficient time available but rather as a vital necessity if the decision-makers of the future are to learn necessary skills for preventing the world from repeating the environmental disasters of the past. Science teachers have a pivotal role in this essential educational process. Another promising approach to integration that we are investigating with our current research is via inter-disciplinary teaching in which science teachers collaborate with teachers of other subjects (e.g., languages, mathematics, society & environment) to develop and teach ethical dilemma stories, including students in learning to write their own stories.

ABSTRACT

This study focused on 4th grade students' perceptions of the Nature of Science. Students were asked to draw and label concept maps about their knowledge and perception of science. They were interviewed to explain their maps. Analysis revealed an equal number of nodes drawn by both male and female students. However, female students used a greater variety of colors to construct their maps. Students were asked to respond to 11 questions developed by the researchers. Data gathered showed students chose science as a favorite subject, were interested in science careers, and perceived science as important. However, students had difficulty naming a scientist, identifying uses of science in everyday life, and designating scientific inventions. School, parents, and television were identified as their main sources of scientific learning. Results suggested science was being taught as abstract textbook concepts with few connections made to real world experiences, and limited time spent teaching about important scientists and inventors. Researchers recommend trade books dealing with science topics, biographies of scientists, and hands-on activities be given a greater emphasis in science teaching and learning in the elementary school.

Keywords: *science education standards, nature of science, concept maps, mind maps*

INTRODUCTION

The Nature of Science (NOS) has been described as the values and beliefs of scientific knowledge and development (Lederman, 1992). Research has provided many definitions, meanings, and interpretations regarding the NOS such as using science to solve everyday problems which involve both scientific content and processes. According to Bell (2008), "using science in our everyday lives requires understanding the nature of science" (p. 1). Although no single universal step-by-step scientific method captures the complexity of doing science, a number of shared values and perspectives characterize a scientific approach to understanding nature. The National Science Teachers Association (NSTA) states the following concepts are important to understanding the Nature of Science (NOS): scientific knowledge is simultaneously reliable and tentative, and testable against the natural world; creativity is a vital, yet personal, ingredient in the production of scientific knowledge; science is limited to naturalistic methods and explanations and; a primary goal of science is the formation of theories and laws. Further, contributions to science can be made, and have been made by people throughout the world. The scientific questions asked, the observations made, and the conclusions reached in science are to some extent influenced by the existing state of scientific knowledge, the social and cultural context of the researcher, and the observer's experiences and expectations. The history of science reveals both evolutionary and revolutionary changes. With new evidence and interpretation, old ideas are replaced or supplemented by newer ones. While science and technology do impact each other, basic scientific research is not directly concerned with practical outcomes, but rather with gaining an understanding of the natural world for its own sake.

Bell also stated that teaching students about the Nature of Science (NOS) helped students view science as a dynamic process. Additionally, it helped them develop richer understandings of physical science, increased their interest in studying science, showed them the human side of science, and provided them with accurate views of the scientific enterprise. Teaching the NOS begins the process of producing scientifically literate citizens. Benchmarks for Science Literacy (AAAS, 1993) and the National Science Education Standards (NRC, 1996) advocate students should possess adequate mastery of the NOS. Lederman and Lederman (2004) listed seven aspects of the NOS relevant to K-12 students' lives. These aspects involve an understanding that scientific knowledge is tentative, subjective, partially based on human inference, empirically- based, socially and culturally embedded, and dependent upon human imagination and creativity.

Concept mapping, as a tool to visualize and communicate conceptual understanding, has been extensively studied in the context of science education. According to Rye (1995), concept mapping is especially suited for science because it can support learners in their thinking about relationships between concepts. Variations on concept mapping such as Mind Mapping®, which include the elements of color and symbols, are less evident in the literature, but provide relevant possibilities for applications in content domains such as art education, as well as, science education.

A concept map is a graphical representation of a domain of knowledge consisting of nodes representing concepts, objects, or events connected by directional links that describe the relationships among and between the nodes. Concepts are arranged so that the most general concepts appear at the top or middle of the concept map, with less inclusive and more specific concepts emerging below or around (Novak, 1977, 1978, 1998, 2004). An exploration of the international literature reveals Mind Mapping® as a teaching and learning method that emphasizes visual representation and offers a variation of concept mapping. This method was developed by Tony Buzan (2006) and integrates the use of color, symbols, or pictures with the words. The creation of concept maps may also be facilitated with the use of mapping software such as Inspiration® that allows learners to create a concept map using the various symbols and features of the program.

The *Atlas of Science Literacy* (2001) states that "Project 2061 is a long-term effort to improve education for all citizens to attain science literacy-that is, a basic understanding of the natural and social sciences, mathematics, and technology, and their interactions"(p. 3). Project 2061's *Science for All Americans* (1900) and *Benchmarks for Science Literacy* (1993) proposed standards for each grade level (See Appendix A) in areas such as Nature of Science, Nature of Mathematics, Nature of Technology, Physical Setting, and The Living Environment. Most states were encouraged to incorporate Project 2061 standards into their science standards. The researchers sampled science programs of several states that were representative of each region of the continental United States to examine in terms of their inclusion of the standards suggested by Project 2061.

Research Questions

This study focused on investigating some of the content and aspects of the Nature of Science as understood by fourth grade students. Students were asked to respond orally in an interview format, and to visually represent via concept maps some of the science content they had been taught. The research questions were: What are fourth grade students' perceptions of the Nature of Science?; What science concepts and information are fourth grade students able to articulate?; and, are there any differences in attitudes towards science expressed in terms of gender?

Participants

Participants in this study were 12 fourth grade students in a self-contained, public, elementary school in southwest Alabama in the United States. There were eight girls and four boys. One of the boys was identified as a gifted student and participated in the gifted program provided by the local school system. All of the students were Caucasian and eleven of the twelve were born in the United States. One girl was born in Russia and adopted by an American family. All participants were either nine or ten years of age, and were from middle to low socioeconomic groups.

METHODS

The classroom teacher used concept maps and Venn diagrams as part of her science instruction in the unit taught before the researchers collected data. As a follow up to the teacher's instruction, the researchers conducted a whole class activity in which all the students constructed a concept map representing their individual families. This was used as a review to ensure students understood how to construct a concept map and were able to focus on the content during the actual data collection. To complete this task, each student was provided a 42.9 x 27.8 cm piece of paper and a pack of 10 felt tip markers of assorted colors. The students were instructed to write the word "science" in the center of their paper and then draw everything they could think of to describe science. They were given 20 minutes to complete their concept/mind map.

After completing their maps, the researchers interviewed twelve of the students whose parents signed a permission slip. Not all parents of the children in the class were agreeable to the interview process because of their concerns about their child being audio or videotaped. The classroom teacher explained in the letter asking for permission for their child to participate in the research that the audio or videotapes would be destroyed after being transcribed. Some parents were worried about their child's audio or video interview being played in front of an audience, or posted to the Internet.

These twelve students were asked to interpret their concept map in reference to the individual symbols, pictures, and words they placed on their concept map. The researchers also inquired about the source of the students' learning of the various concepts. In the second part of the interview the following 11 questions were asked: What is your definition of science; tell me something you know about science; how do we use science in our everyday lives; where have you learned science; do you like science as a subject in school, why or why not; is science important, why or why not; what do scientists do; can you name a scientist; do you think you would like to work in a science field, why or why not; and, do you think it is easier for boys or girls to learn science, why or why not?

RESULTS

Each concept/mind map was analyzed in terms of demographic information, (school, grade, ethnicity, and age,) as well as quantitative data (number of nodes, levels, symbols, and colors generated). (See Table 2) Triangulation, "a validity procedure where researchers search for convergence among multiple and different sources of information to form themes or categories in a study" (Creswell & Miller, 2000, p.126), was pursued as multiple researchers engaged in the data analysis.

The *nodes* were counted in each drawing. A node is a concept/idea, or sub-concept/idea; the *level* indicated how many layers of concepts came from the original concept representing the levels of the hierarchy; the *symbol* was anything drawn to represent a concept; and *color* represents how many different colors were used in the visual representation. (Example: plant>leaves> smooth. This would be three nodes, three layers, no symbols, and one color.) Number of nodes, levels, symbols, and colors, were calculated by multiple researchers for reliability. (See Table 1)

The number of nodes identified in the maps by females in the first through fourth levels appears greater than the males. In levels six and seven the males appear to have identified more nodes than the females, although the number of nodes identified is minimal. The number of colors used by the females was more than the colors used by the males. The number of females and the number of pictures drawn by females was more than drawn by the males.

Table 1 Number of nodes from concept/mind map

	Level 1	Level 2	Level 3	Level 4	Level 5	Level 6	# of colors	# of pictures
Boy 1	6	13	9	4	3	1	6	0
Boy 2	6	26	0	0	0	0	6	5
Boy 3	7	14	3	0	0	0	1	2
Boy 4	4	6	3	1	0	0	11	0
Girl 1	6	2	2	1	0	0	2	3
Girl 2	11	4	4	1	0	0	10	0
Girl 3	7	24	0	0	0	0	11	2
Girl 4	8	15	3	0	0	0	8	3
Girl 5	4	11	0	0	0	0	5	0
Girl 6	9	10	6	1	0	0	10	4
Girl 7	10	5	0	0	0	0	11	0
Girl 8	4	4	3	2	0	0	6	4

The science concepts represented by the students' drawings on their concept maps were analyzed and classified by a panel of professors from the elementary methods faculty of the researchers' University to determine which standard the concept would fall within, based on Project 2061's suggested areas. The panel was unanimous in their findings. It was noted by the panel that not all of Project 2061's areas of standards were represented on the students' concept maps. In fact, the science concepts identified by the panel was limited to four areas: Nature of Science, Nature of Mathematics, Physical Setting, and The Living Environment. (See Table 2)

Table 2 Summary of 4th Grade Science Content Standards Found On Concept Maps

Student	Nature of Science	Nature of Mathematics	Physical Setting	The Living Environment
Dylan 10	1		12	8
Russ	2		2	
Dylan 11	1		1	
Lauren	1		2	
Tatiana	1		1	3
Tessa	2		11	
Emily	4		11	2
Madison	2		3	4
Patricia	2	1	3	1
Austin	1		6	1

Responses to the 11 questions were tallied and analyzed for emerging themes. Some of the questions appeared to yield differences in attitudes by gender, although most did not. Some questions were more difficult for the students to answer than others. However, the researchers found that most of the students' answers were reflective of their recent science unit of instruction on astronomy.

When asked about the definition of science, the male students stated that there were particular areas of science that are important to know about like planets, and space. Further, they stated that science was their favorite subject and it helps people learn about the earth and things in it. The female students said that science helps teach about nature, the world, and projects. However, several girls replied that they were not sure, or didn't know how to define science.

Boys named the four states of matter, the animal kingdom, electrical energy, space, oceans, meteorologists, power, lights and constellations when asked what they knew about science. Girls listed astronauts, dinosaurs, rocks, fossils, using science to figure things out, the earth's revolution around the sun, how the sun makes food and energy, and being careful not to pollute the sky and earth. A couple of girls said they couldn't remember anything about science.

A question about how science is used in everyday life yielded few responses. The boys mentioned fire for welding, matter is in everything, astronauts study space, marine biologists study fish, electricity in lights and some said they didn't know. The girls listed electricity, water, paper made from trees, enjoying nature, things seen outside, plants, and being as "green" as possible. As before, a few girls said they don't know how science is used in everyday life.

Both male and female students struggled to name a scientific invention. The boys named the telescope and radio as scientific inventions. Some of the boys could not think of an answer. The girls identified electricity and water as scientific inventions. However, several of the girls could not respond to the question.

Where science was learned by the students resulted in a variety of answers. The boys mentioned textbooks, their fathers, television, and church. The girls gave credit to learning science from school, parents, their mothers, television, walking outside, and textbooks. According to the boys and girls, watching nature and science-oriented programs on cable channels was a good way to learn about science.

The majority of both boys and girls stated that they liked to study science as a subject at school. All of the boys gave a positive response. With the exception of two girls who answered negatively, the girls had a positive attitude toward studying science as well.

All the male students agreed that science is important. The female students, however, gave mixed responses. Five of the female students agreed with the male students that science is important, but two of them said no, science is not important, and two other female students said they were not sure if science is important or not.

Describing what scientists do resulted in a diverse list from both male and female students. The males responded by saying that scientists do research, look for deeper and deeper meanings, show how things are related to each other, and study the earth, planets, and rocks. One of the boys said he didn't know and another boy did not respond at all. The females listed making inventions, studying rocks, finding out where dinosaurs lived, figuring out ways we can use things, researching, and finding out what happened to people and why as work conducted by scientists. As with the male students, one female student did not respond to this question.

Asking the students to name a scientist was possibly the most difficult question posed by the researchers. Two of the male students were able to respond and two were not. Similarly, two of the female students were able to name a scientist, and six were not. The scientists specified by the students were Albert Einstein and Werner von Braun. Naming these particular scientists may have been directly related to their recent unit of study on astronomy.

Working in a science field was seen as a positive career choice by three of the boys. However, one of the boys stated that he was not sure if he would like to have a career in science or not. The female students were also divided in their opinions about choosing a science-related career path. Four of the girls said yes they would like to work in a science field, one said definitely no she would not, and three said they were not sure.

Three of the boys and two of the girls felt learning science was easier for boys to learn than girls. One boy felt it was easier for boys to learn science than girls because of the gross things involved in learning science like dissecting frogs. Two of the girls said no, it is not easier for boys to learn science than girls. Interestingly, one boy and four girls stated it was of equal difficulty for both sexes. These students' answers may have been influenced by the fact that their science teacher is a female.

DISCUSSION

The results of the study were limited by the small sample size used and therefore, generalizations to other fourth grade classrooms are extremely limited. The population was confined to one fourth grade classroom from which twelve children's concept maps were analyzed and they were later interviewed. The small sample number was a consequence of not being able to interview all of the subjects who had participated in the construction of concept maps due to not being able to gain permission for the audio or videotaped interviews. While parents did not object to the concept maps, many were wary of their children being audio or videotaped. Any follow-up research should be done in multiple grades, schools, regions of a country, and various countries. The following is a discussion of the results as they relate to the research questions.

The beliefs about the Nature of Science (NOS) of these fourth grade students were examined through the construction of concept/mind maps and a follow-up interview. The data were collected from the analysis of their concept maps and the answers given to 11 interview questions devised by the researchers. This study was conducted late in the school year after the majority of their standardized testing had occurred. Some of the responses provided by the subjects were probably influenced by what they were currently studying or had just completed. The teaching of science may have been neglected due to the review for, and administration of, the high-stakes standardized tests which emphasize reading and math skills.

Upon analysis of the interview questions it was apparent that the children reported science as one of their favorite subjects, they were interested in science careers, and perceived science as important in everyday life. With the exception of a couple of students, the subjects were unable to name a scientist, identify uses of science in everyday life, and list inventions made by scientists.

Males identified science concepts such as the states of matter, the animal kingdom, electrical energy, space, oceans, meteorologists, power, lights and constellations when asked what they knew about science. Male students viewed the NOS as an exploration of science concepts and processes, such as space, matter, and electricity. One male student said “Fire is plasma. Say if you are a welder, like my father, you heat the gases until they become the fourth stage of matter, plasma. Basically your body is matter and you couldn’t be who you are without matter.” He relates a science concept studied in school to his everyday life, his father’s career. Males said that scientists explore both concrete and abstract concepts with no mention of the practicality of their discoveries. One male stated “Scientists create things, they research and depending on what type of scientist they are, they research a topic and like I did with concept map, they get deeper and deeper and branch off and relate.” The boys appeared to be more interested in science as a means to explore both concrete and abstract concepts, such as space and forms of matter. One boy stated the reason he was interested in science was “because I can’t just memorize like say history, like history, but with history you memorize dates for the test and me I like science because you can get deeper and deeper with your information.” The researchers then asked him if he felt history is limited. He responded “History is limited because it is hard to relate to and there was only so much of it that was recorded.”

Females listed astronauts, dinosaurs, rocks, fossils, using science to figure things out, the Earth’s revolution around the sun, how the sun makes food and energy, and being careful not to pollute the sky and earth. The students had just completed a unit dealing with astronomy which may have influenced their identification of those particular science concepts. Two girls said they couldn’t remember anything about science. The female students in this study stated that the NOS involved practical applications of science for animals and the ecology of the planet. One female stated “Science helps figure out ways we can use things and ways we can figure things out and use it.” Another girl said “It helps you learn about projects and everything to do with the outside world.” The girls appeared to be interested in science that deals with inventions and practical applications like helping animals and the preservation of the earth like solving problems such as providing clean air and water.

The differences between the views of males and females in this study may indicate that the sexes may have a different orientation towards the learning of science, the uses of sciences, and the investigation of science. If these findings occurred again in multiple studies with larger populations, multiple grade levels, and in different countries, the implications for teachers, textbook suppliers, and test makers would be very significant.

Three of the boys and two of the girls felt learning science was easier for boys to learn than girls. One boy “felt it was easier for boys to learn science than girls because of the gross things like dissecting frogs” while a girl said “boys, because boys are more astronauts than girls.” Another boy said “Since I am a guy, it is easier for the guys.” Interestingly, one boy and four girls stated it was of equal difficulty for both sexes. One female stated “because they are both being taught they can learn the same amount so it is hard for both.” One factor of this study to consider is that their science teacher is a female, all of the previous grade level teachers were female, and some of the children may be influenced by traditional roles for males and females as experienced in their family settings.

The children’s inability to identify science concepts, scientists, everyday uses and inventions of science, and the relationship between science, mathematics, and technology may have been influenced by the science curriculum adopted by the state and public school district. Although science is supposed to be taught everyday in every grade level, due to the importance placed on standardized testing which emphasizes reading and math skills, science may not be taught as often or as thoroughly as other subjects.

Project 2061 identifies many standards for science that should be emphasized in each grade level, including the Nature of Science, Mathematics, and Technology. Although a program called the Alabama Math, Science, and Technology Initiative (AMSTI) is supposed to be implemented state wide, budget cuts and high-stakes testing have limited AMSTI's success. Many states have standards specified for science, but a selection of science programs from states in different parts of the United States indicates science instruction is limited to the following four areas for most states: Nature of Science, Nature of Mathematics, Physical Setting, and the Living Environment. Of the states randomly selected, three explicitly stated standards for learning about the Nature of Science, one state program identified standards for learning about the Nature of Mathematics, and one state listed standards for learning about the Nature of Technology. However, all the state programs reviewed by the researchers had standards for teaching about the Physical Setting and the Living Environment.

Akerson, Buzzelli, and Donnelly (2010) stated that "it is critical that teachers have adequate views of NOS and explicitly teach NOS. Pre-service teachers can improve their NOS conceptions by participating in science methods courses that explicitly emphasize NOS" (p. 213). Therefore, it is suggested that this standard be taught overtly in the classroom at every grade level in order to attain mastery and retention of knowledge about the Nature of Science. Sometimes the science curriculum can negatively impact the teaching of science as well as the retention of the science concepts for immediate and delayed testing. Akerson, Buzzelli, and Donnelly (2010) stated that "The main factors that hindered or facilitated teaching NOS for preservice teachers were the influence of the cooperating teacher and the use of the science curriculum" (p. 213). It is also suggested that science by taught using an inquiry, hands-on approach with real world connections to the lessons and concepts. This would move science from an abstract, textbook driven curriculum to one in which students learn through a constructivist approach to teaching while seeing an everyday relevance of science to their lives. The researchers recommend that the teacher involved in this research study incorporate science trade books written for children such as biographies of current and historic scientists and other nonfiction works, and appropriate technology into their science instruction to enhance the teaching and learning of abstract science concepts, and to encourage the interest of both genders in future science courses and careers. This may be a helpful suggestion for elementary schools that have large literacy and mathematics blocks with limited time allotted for science.

Future research on this topic might include surveying additional classrooms of the same grade level, different schools with diverse student attributes, and possibly sampling all elementary grade levels. Additionally, reviewing additional state science curriculums may reveal which standards, concepts, processes, and dispositions are actually being taught due to the impact of knowledge about the Nature of Science, high-stakes testing, the local science curriculum, and/or training of the classroom teacher.

Appendix A

Project 2061's Fourth Grade Content Standards

1. The Nature of Science
A. The Scientific World View, Scientific Inquiry, and The Scientific Enterprise
2. The Nature of Mathematics
A. Patterns and Relationships, Mathematics, Science, and Technology, and Mathematical Inquiry
3. The Nature of Technology
A. Technology and Science, Design and Systems, and Issues In Technology
4. The Physical Setting
A. The Universe, The Earth, Processes That Shape The Earth, Structure of Matter, Energy Transformation, Motion , and Forces of Nature
5. The Living Environment
A. Diversity of Life, Heredity, Cells, Interdependence of Life, Flow of Matter and Energy, and Evolution of Life

Various States Fourth Grade Standards

Alabama's (SE United States)
1. Describe how electrical circuits can be used.
2. Compare different pitches of sound.
3. Recognize how light interacts with transparent, translucent, and opaque materials.
4. Describe effects of friction on moving objects.
5. Describe the interdependence of plants and animals.
6. Classify animals as vertebrates or invertebrates and as endotherms and ectotherms.
7. Describe geological features on Earth.
8. Identify technological advances and other benefits of space exploration.
9. Describe the appearance and movement of Earth and its moon.

Oklahoma's (Southern part of Midwest United States)
1. Observe and Measure
2. Classify
3. Experiment
4. Interpret and Communicate
5. Inquiry
6. Position and Motion of Objects
7. Electrify
8. Characteristics of Organisms
9. Properties of Earth Materials

California's (West Coast of United States)
1. Electricity and Magnetism
2. All organisms need energy and matter to live and grow.
3. Living organisms depend on one another and on their environment for survival.
4. The properties of rocks and minerals reflect the processes that formed them.
5. Waves, wind, water, and ice shapes and reshape Earth's land surface.
6. Scientific meaning

Washington’s (NW United States)
1. Measurement of Force and Motion
2. States of Matter
3. Heat, Light, Sound, and Electricity
4. Earth in Space
5. Formation of Earth Materials
6. Focus on Fossils
7. Structures and Behaviors
8. Food Webs
9. Heredity and Adaption

Connecticut’s (NE United States)
1. Forces and Motion
2. Matter and Energy in Ecosystems
3. Energy in the Earth's Systems 4. Science and Technology in Society

Indiana’s (Midwest United States)
1. Collaboratively carry out investigations
2. Skills and techniques to answer questions and solve problems
3. Investigate changes of the Earth and sky.
4. Increasing knowledge of the variety of organisms
5. Apply mathematics in scientific contexts.

EXPLORING THE EFFECTS OF DEVELOPING COLLABORATION IN A PRIMARY SCIENCE TEACHER COMMUNITY

Martin Krabbe Sillasen

VIA University College
&
Department of Education, Learning and Philosophy
Aalborg University, Denmark

msil@viauc.dk

ABSTRACT

This paper presents findings from a qualitative study to explore factors that may facilitate sustainable changes of collaboration in a primary science teacher community in one school. The context for this study is a development project aimed at improving science teaching by changing teacher's collective work in schools and developing network between schools. The objective is to improve the collaboration within primary science teacher communities on sharing best practice and developing new ways of teaching. This study represents an in-depth approach to explore possibilities and constraints for how a development project can facilitate sustainable change in primary science teachers' collaboration.

The purpose of the research project introduced here is to examine closer, why many development projects fail to produce sustainable results. The framework of McLaughlin and Talbert (2006) on *Building teacher learning communities* is introduced to investigate factors that may facilitate sustainable changes of the collective work in science teacher communities. Examples on how McLaughlin and Talbert's analytical framework is used as a diagnostic tool are presented. Such an analysis provides a vantage point for researchers to outline potentials and constraints in a schools effort to transform the culture of the primary science teacher community.

Keywords: *Teachers professional development, Teacher practice, Developing science teacher communities.*

INTRODUCTION

In the Danish primary and secondary school system the collaboration between science teachers is characterized by practical issues, e.g. maintaining laboratories and teaching materials. These tasks are well organized in most Danish schools (Andersen, 2006). But research has shown that primary science teachers lack the opportunity to engage in collaborative processes, where focus is sharing best practice and development of new ways of teaching (Abell & Lederman, 2007; Sørensen, Horn, & Dragsted, 2005). This means, that the prevailing culture in many schools is one of individualism and lack of collaborative processes about pedagogical innovation.

Within a Danish context it has been suggested, that to achieve and maintain a high level of quality in science teaching, it is necessary to develop the collaboration in science teacher communities. This collaboration should focus on sharing best practice, norms, values and collaborating about new ways of teaching (Andersen, 2006; Sølberg, 2007).

EVIDENCE OF THE EFFECT OF DEVELOPING TEACHER COMMUNITIES

Developing teacher communities in schools align with empirical evidence of the most effective strategies of teacher professional development. Statistical studies aimed at, among other, estimating the effect of professional community on student outcomes support the hypothesis that students do better in schools where teachers take collective responsibility for the success of all students. They also provide evidence that students' socioeconomic background had less effect on their outcome of education if their teachers were engaged in collaborative teacher environments (Lee & Smith, 1996; Lee, Smith, & Croninger, 1997). In their large-scale study conducted in England, Bolam et al. compared professional learning community characteristics with student outcome from a national pupil assessment database. They found that there was a statistically significant relationship between student outcome in schools where developing and planning curriculum activities is collective work in a teacher community (Bolam et al., 2005). In another study researcher's found evidence that students performed better in schools where teachers collaborated to develop and assess teaching interventions (McLaughlin & Talbert, 2006). A national survey in Denmark supports this evidence (Mehlbye & Ringsmose, 2004). They identified several factors that characterized high performing schools, e.g. a collaborative teacher community; leadership that involves the teacher community in decision processes; an organization within the school where division of responsibilities are well structured; and a school that is open to new innovations.

These empirical data provide evidence that developing teacher communities in schools can generate improvements in teachers' performance which in the end has a positive effect on the student outcome.

DEVELOPING SUSTAINABLE TEACHER COMMUNITIES

The development of teacher communities can influence teachers' motivation; provide extra resources for teaching; create spaces for sharing best practice; and increase reflexivity on pedagogical issues among teachers in the community. This can prompt change in the way that science teachers teach and think about teaching science. However, many development projects focusing on changing teachers' attitudes and work routines fail to succeed these objectives. Teachers involved in change processes often revert to their former work routines as the development project ends, and resources and the external pressure within the development projects stops (Fullan, 2007). But what characterizes a development process that can generate sustainable changes within a teacher community?

I have adapted McLaughlin & Talbert's framework (2006) on *building school-based teacher learning communities* to investigate factors that may facilitate sustainable changes of the local science culture in a primary science teacher community.

The results presented in this paper are based on a qualitative study of developing a primary science teacher community in one school. The objective of the development project is to provide better opportunities for primary science teachers in schools to collaborate about curriculum development and new ways of teaching.

THE NATEKU-PROJECT

The context for the research presented here is a development project co-funded by the Ministry of Education in Denmark and 4 municipalities with a budget of approximately

800.000 Euros. The development project, called the NaTeKu-project, is a 3-year project that was initiated in 2007. The NaTeKu-project involves 80 primary science teachers in 20 schools in 4 municipalities. The primary objective is to develop collaborative processes in primary science teacher communities in the participating schools to facilitate sustainable change of the collective work. The secondary objective is to develop scaffolding structures in each municipality that can support networking between teachers from different schools. Networking provides opportunities for teachers to compare different models of collaboration and to share knowledge about curriculum development. Stakeholders in this process are the municipalities, local science centers and science coordinators associated to each municipality.

The managing body of the NaTeKu-project is the House of Science (www.naturvidenskaberneshus.dk) which is part of the National Center for Education in Science, Technology and Health-science (www.nts-centeret.net).

Project-managers from the House of Science support the scaffolding process in each municipality as well as in each of the participating schools.

RESEARCH FOCUS

The scope of the research reported in this paper is not concerned with whole school development, but is limited to a study of a primary science teacher community in one particular school.

Researchers have been involved from the early stages of the NaTeKu-project. They will follow the developmental process and its impact on changing the collaboration in primary science communities in the participating schools as the project progresses.

This will provide the opportunity to investigate:

1. *What are the possibilities and constraints for developing the collaboration in primary science teacher communities?*
2. *How does the content of the collaborative work in a primary science teacher community make sense to individual science teachers own practice?*

THEORETICAL FRAMEWORK

McLaughlin & Talbert's notion of a *teacher learning community* is a shared space, where teachers work collaboratively to reflect on their practice, examine evidence about the relationship between practice and student outcome, and make changes that improve teaching and learning for the students in their classes (McLaughlin & Talbert, 2006). A teacher learning community is positioned at the "meso-level" between the "macro" or system-level and the "micro-level" of realities in the classroom. It represents a shared space where teachers can negotiate and interpret information from the larger educational system. In this sense the teacher learning community allows teachers to connect their work to larger system context.

A strong teacher learning community is one that focuses on improving practice, shared accountability, establishing ownership of the development process among most of the members of the community (McLaughlin & Talbert, 2006).

Their notion of building a teacher learning community resonates with the objectives of the NaTeKu-project as well as the previous discussion about sustainable collaboration in primary science teacher communities that focus on sharing best practice and developing new ways of teaching.

There is, however, a difference between developing primary science teacher communities in the NaTeKu-project, and building a teacher learning community as described by McLaughlin and Talbert. That is, none of the primary science teacher communities in the NaTeKu-project examines evidence about student outcome as a starting point for developing collaborative work. Their entry point is to analyze current collaborative efforts about planning curricula and teaching. The second step is to inquire and negotiate what elements of their collaborative work can be improved, and how they can improve it. The third step is then to realize initiatives and assess how they improved their collaboration at multiple levels in the community. During all three steps the municipalities organized network-meetings, where teachers shared knowledge with teachers from other schools participating in the project.

This model was a deliberate approach to allow different teacher communities to organize their own collective work within schools, and then to network with teachers from other schools to compare collective initiatives.

It is crucial to engage all teachers within a community in the process of designing the change initiatives, because if the change is to be sustainable, teachers need to develop ownership of the collaborative activities. Fullan argues that

> *…implementation and continuation [of change processes] are not just technical problems. Even the best technical ideas, in the absence of passion and commitment, do not go very far. … unless [teachers] are bound together by a moral commitment to growth, empathy, and shared responsibility, [they] are as likely to replicate the prevailing school culture as to change it.* (Fullan, 2007)

Following this argument it is important for the managing body of the developmental process to consider, how they can construct a scaffolding structure within the project to support stakeholders at all levels in their process towards the objectives of the developmental process.

In their model Mclaughlin and Talbert (2006, chp. 3) outlines three important factors that support the process of changing a school culture:

1. *Teacher learning community development, spread and sustenance depends on proactive leadership within and outside the school.*
   In the NaTeKu-project there are four levels of leadership, two outside and two inside the school. Outside the school the managing body of the project and municipal science coordinators collaborate on creating scaffolding structures that supports the developmental process on each school. Inside each school the principal and "community coordinators" play different roles in scaffolding the developmental process.
2. *A teacher community of practice develops through joint work on curriculum development and new ways of teaching.*
   The entry point into the change process can e.g. be a subject like primary science. That is the case of my research.
   In the following analysis of a primary science teacher community I present indicators of potentials and constraints for developing the collaboration between teachers.
3. *Teacher learning in a community depends on how well the collaboration is designed and guided*.

That is to say how well organized an effective learning environment is created for the teachers. The crucial point is how well activities are organized within the school, and what kind of scaffolding structures have been constructed to support networking between schools in the NaTeKu-project?

In their research McLaughlin and Talbert found that teacher learning communities move through a number of developmental stages to become strong, and that the transition between these stages depends on how a teacher learning community address challenges that relates to all three factors listed above (McLaughlin & Talbert, 2006).

In this study there are given examples on how McLaughlin and Talbert's analytical framework is used, as a diagnostic tool, to determine, how well the development process is implemented in a primary science teacher community. Such an analysis provides a vantage point for researchers to outline potentials and constraints in a schools effort to transform the culture of the primary science teacher community.

METHODOLOGY

In the qualitative studies in the NaTeKu-project, communities of primary science teachers in three schools were asked to participate. These schools were chosen on the basis of a quantitative survey that provided broad categories of answers to the research questions. This included information about the primary science teachers characteristic and attitudes about collaboration in different contexts as well as general trends of their teaching.

The major challenge in the qualitative research process was to build trustful relationships with the primary science teachers to collect information about their collaboration. First I observed a particular primary science teachers' daily work during 6-8 days. These observations allowed me to study the primary science teachers' relationships with other teachers in the primary science teacher community and their joint activity, actions, rituals, use of language and artifacts. These elements provided important inferential keys to the primary science teacher community under study (Miles & Huberman, 1994).

Based on observations I interviewed key-informants with-in and outside each primary science teacher community. In these interviews informants acted as co-interpreters of my previous observations of relationships, events, actions or use of artifacts. In this perspective, events that I, as an observer, and the informant, as an actor, participated in forms a common reference in the interview (Kvale, 2004).

SETTING THE SCENE

One of the schools in the qualitative study is chosen to illustrate how McLaughlin and Talberts' framework can be used as a diagnostic tool to determine the schools effort of changing the local scientific culture in their primary science teacher community. All names the following presentation are pseudonyms.

The school is situated in village in a rural district in the western part of Denmark. The population consists of many middle- and few low in-come families. In the village there are small and middle sized industries, where many local people are employed. In the rural district around the village there are many farms of various sizes.

There are 400 students in the school, ranging from grade 0 to grade 9.

The school employs about 35-40 teachers. They are organized in three departments related to different grade levels (Lower department: grade 0.-3., Middle department: grade 4.-6. And Upper department: grade 7.-9.). Each department has autonomy to make decisions about cross-curricular activities.

Primary science is taught from grade 1 to grade 6. There are some transitions of science teachers between the departments. This means that the primary science teacher community includes teachers from all three departments.

Two experienced science teachers' had the role as coordinators in developing the primary science teacher community in the NaTeKu-project. They organized activities and provided supervision for the other participants in the development process.

Peter is one of these coordinators. He usually teaches biology and physics in the upper department (grade 7.-9.). Peter does not teach primary science in the other departments. But he is one of the driving forces in the schools effort to develop a coherent scientific culture. The schools participation in the NaTeKu-project provided resources and a scaffolding structure to support this process. Peter is a key-player, because he acts both as a moderator of the joint activities in the primary science teacher community, as well as being a mediator of the dialogue about developing the science culture with the science teachers in the upper department.

Susanne is the other coordinator. She teaches primary science in both the lower department (grade 0.-3.) and the middle department (grade 4.-6.). She is recognized as a very competent primary science teacher in the community. Her colleagues talk about her creativity in developing new ways of teaching as well as challenging students on their communicative skills in science. She is also considered to be a teamplayer in collaborative situations. In these aspects she acts as a rolemodel for many of the other primary science teachers.

Peter and Susanne complement each other in their central position in the developmental project. Peter is more structured and able to keep focus on the objectives of the change process. Susanne is very good at challenging their usual work routines and come up with new ways of teaching or topics that they can collaborate about.

Their collaboration with each other and other teachers in the community is vital for developing collective activities.

The school-principal delegated all decisions about the implementation of development objectives to stakeholders within the primary science teacher community. Peter and Susanne are key-players in the process of negotiating what and how development activities should be implemented in the primary science teacher community. Their role is also to engage the other primary science teachers in the development process.

FINDINGS

In this section some findings about possibilities and constraints of developing collective activities within the science teacher community is presented. The findings relates to the three dimensions of McLaughlin and Talberts framework. In the last part of the section the teachers own assessment of the outcome of the development project are presented and discussed.

SUPPORTIVE LEADERSHIP TO DEVELOP THE TEACHER LEARNING COMMUNITY

Research shows that supportive leadership is important for the success of educational change processes (Fullan, 2007; Hargreaves & Fink, 2006). As discussed earlier there are four levels of leadership in the NaTeKu-project. In this section I will elaborate on the two levels inside the school: The role of a community coordinator and the principal.

The role of a "community coordinator"

Research on community-building in business has shown that a skilled *community coordinator* is a key-factor in developing an effective community of practice (McLaughlin & Talbert, 2006; E. Wenger, McDermott, & Snyder, 2007). The coordinator work both to organize the community's work and to building an effective learning environment for the community.
In the particular case presented here Peter and Susanne share the role of being community coordinators in activities in the NaTeKu-project. Peter focus on both organizational issues and building the collaborative practices. The following excerpt shows what role he plays:

> I: *What has participation in the NaTeKu-project mattered for the primary science teachers in this school?*
>
> Peter: *It means that we have focused on developing new ideas about teaching and what we want to improve. For example is working with innovation something new. […] But we have also started to work on developing a curriculum that creates coherence between primary science in the middle department and other science subjects in the other department.*

In this excerpt Peter argues that they have focused on two activities in the NaTeKu-project: Developing new teaching ideas (innovation as a curriculum topic) and creating a coherent curriculum that will ease student transitions between the different departments. The teachers in the community agreed to commit to a collective curriculum that covered 50% of the teaching in primary science. This is a big issue for many teachers in Denmark, because there is a long tradition about teacher-autonomy in planning their teaching.

Peters' role as a community coordinator includes promoting communication between members and departments, to ensure that all are informed about the progression of the community in different departments.

However, there are problems with Peter's role as a community coordinator. When I asked another primary science teacher, George, whether he participated in the development project, he answered: *Yes I do […] but I don't actually know who the coordinator is […] I assume that its' Peter. But it is a long time since I heard from him about the project.* George expresses doubt about who the coordinator in the project is, and that it is a long time since he was involved. George is associated to the lower department which is physically isolated from the other departments. They are situated in their own building. This means that George does not have a daily contact with the other primary science teachers involved in the project. So collaboration and discussions with other primary science teachers are scarce, compared to other primary science teachers in the community.

These problems expose two important constraints in the process of engaging all primary science teachers in the community in the developmental activities. First, it is crucial for all stakeholders in the development process to be informed about who has the role as community coordinator, and what his or hers tasks are. Clear information about division of responsibilities is crucial for all stakeholders to develop ownership towards the development activities. In the excerpt George states that he is not well informed about who the community coordinator is, and what his own responsibility is. Second, Georges' association to the lower department imposes a structural constraint on his possibility to engage in daily discussions with other members of the primary science community. For Peter, as the community coordinator, it is important to spread communication about community activities to ensure that e.g. George develops commitment towards the collective activities within the primary science teacher community.

Susanne's role as a coordinator is more to mediate ideas about best practice and inspire others with new tools and ways of teaching. The following excerpt is an example of how another community-member perceive Susanne's role:

> Paul: *Because of our good collaboration in primary science it becomes visible to other teachers what is going on in this subject. She [Susanne] is very creative on teaching and presenting student products. And to get her classes engaged in external teaching activities. So it becomes very visible that we are active in primary science out here. If you walk down the corridor there are many student products from primary science visible. It is difficult not to sense that it is an important subject.*
>
> I: *How does Susanne's creativeness affect you?*
>
> Paul: *Well, it does a little bit,[…] I think that in some way or another you want to surf on the wave that she has produced.*

Paul is a young teacher and a newcomer in the community. He is building his identity as a teacher. We can infer that Susanne's creativity inspires Paul to develop his own professional identity.

Principals' role in transition phases and creating space for collaboration within in school organization

The principal and vice-principal play an important role in supporting change processes. They work along the line of decentralizing decisions to teacher communities about issues that are meaningful for the teachers to express an opinion about. That includes decisions about engagement in and planning of developmental processes. The following excerpt exemplifies how the principal works on creating space for developing teacher-collaboration within the school:

> Principal: *Teachers' engagement in decisions about issues that affects their daily work ensures that they have ownership towards the joint practice of the school. That also includes the primary science teachers' participation in building their community. We [the principal and vice-principal] helped to initiate the developmental project in the primary science teacher community, but withdrew quickly from the negotiations to ensure, that the teachers developed their ownership. But we helped them in formulating the objective on developing a coherent curriculum in science within and between the departments.*

This excerpt shows that the principal was engaged in the beginning of the development project. Actually he initiated the process, because participation in the project was offered by the municipality. And then the principal saw it as an opportunity to develop the collaboration within the primary science teacher community further. After deliberations with the principal, the primary science teachers took initiative and developed their ownership towards the objectives of the development project.

However, the principals' quick withdrawal from designing the development activities also posed a constraint. McLaughlin and Talbert (2006, chp. 4) discusses how proactive leadership is important in all phases of developing a teacher learning community. This is in particular crucial in the early phases of the process of negotiating how development activities are designed and what roles should be played by different actors in the community. In the community under study, the principal withdrew too soon from these negotiations, leaving the responsibility of the negotiation to the community members. The consequence was that not all members of the community were well informed about division of responsibility of the collective activities, and what the role of the community coordinator was, as discussed earlier.

The activity of developing a coherent curriculum within and between the departments is only one amongst several activities that teachers in the community are engaged in. The teachers do not engage equally in all the activities. The principal argues: *Most of the teachers in the science teacher community are core-members in at least one activity. It is a success that so many teachers are committed to the activities in the community.* However teachers' different position in different activities also poses a problem, because a particular teacher that plays an active role in one activity needs to be kept informed about other activities if she/he is to play a peripheral role in these. I observed that this basic level of information transfer was not always present with all members in the community. The principal reflected: *I have to reassess my role in initiating and defining development activities in the future. It is very important that all members in an activity are informed about the objectives, division of labor and who is responsible for the activities.*

Another example of the principals' role in developing the primary science teacher community is in moderating the transition between different stages of the culture.

A few years back he initiated a development process about mapping the different ways of teaching primary science in the school. The objective was to moderate a discussion about how the primary science teachers could collaborate more. The teaching culture was individualistic at that time. Many old teachers taught primary science, and they argued that they could not see the value of sharing knowledge about teaching in primary science. Peter and Susanne argued: *The old teachers were used to planning and teaching being a private matter*. But an opportunity to change this culture appeared because many new teachers that teach primary science were employed in the following years. The young teachers were more interested in sharing knowledge about planning and teaching primary science than the old teachers. And then the NaTeku-project provided the opportunity to develop joint activities within the primary science teacher community.

The principals' engagement in initiating the development processes proved to be vital to transform the culture within the primary science teacher community.

THE DYNAMIC STRUCTURE OF COLLABORATION WITHIN THE SCIENCE TEACHER COMMUNITY

There are some characteristics about the dynamic structure of collaboration within the science teacher community.

First, the core of collaboration in the science teacher community is developing a variety of curriculum and teaching activities. In general there were two levels of collaboration between teachers in the activities. The first level of collaboration was in *micro-communities* where teachers collaborated in small groups on developing joint teaching activities. Teachers in the community valued collaboration in micro-communities because it was a shared space where they could discuss not only practical and pedagogical issues of their teaching practice, but also personal aspects of their life. I observed that teachers in micro-communities were more open about discussing attitudes and values about issues that related to the school culture. In this sense, micro-communities can be a secure space where teachers negotiate their attitudes with colleagues with whom they share personal relationships. The second level of collaboration was *large scale collective activities* that engaged many teachers in the science community from different departments e.g. in developing a coherent curriculum in science. Large scale collective activities were often initiated by the school principal in collaboration with a few teachers that would act as community coordinators for this particular activity.

Second, the *dynamic* notion emerges from observing that the structure of collaboration can have different *configurations* within the teacher community depending on teachers' involvement in different activities. Each configuration corresponds to different activities in the community and reflects that teachers are more or less active in the different activities.

Third, in one particular configuration of collaboration (e.g. the activity of developing a coherent curriculum) there are three degrees of *membership* (see figure 1): Core members, active members and peripheral members (E. Wenger et al., 2007). *Core members* are teachers that take on a pro-active role in activities that constitutes a particular configuration of collaboration. They often initiate actions within the activity and play the role as community coordinators. In the particular configuration presented in figure 1, the role as community coordinator was divided between Peter and Susanne. As the community matures core members will take on the leadership, and move the community along the learning agenda of the activity. *Active members* play a re-active role in activities. They will attend the activities regularly and play an auxiliary role in collaboration with the core members. *Peripheral members* rarely play an active role in activities. They will watch the interaction that takes place between the core members and the active members and show moderate interest for the activity. As teachers' collaboration progresses over time some micro-collaborative environments might mature and produce examples of good practice and teaching.

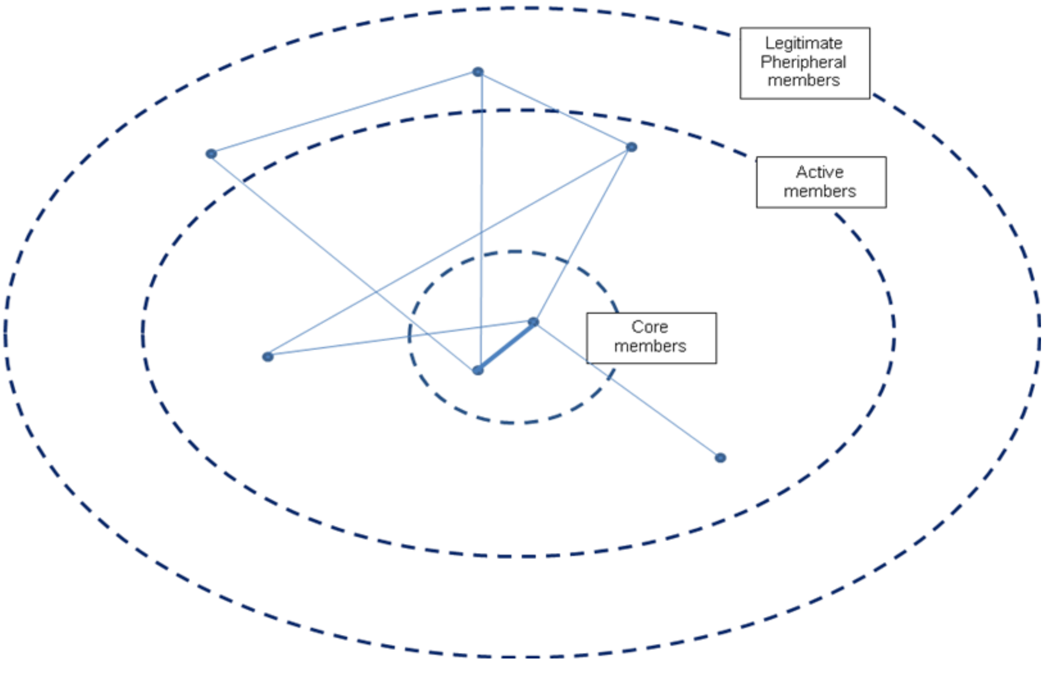

Figure 1: *Structure of collaboration of one activity in the community.* *In this case the activity of developing a coherent curriculum. Each dot represents a member of the community and each line represents a micro-community. A member of the community can have different degrees of memberships in different configurations of collaboration. In this particular case the there are two core members, three active members and two peripheral members.*

Fourth, the strength and quality of collaboration in the science teacher community depends on teachers' mutual engagement in collective activities and that they can have different positions in different configurations of their collaboration. Wenger argues that mutual engagement in collective activities is important for the sustainable development of the community (E. Wenger, 1999-2002). But as Susanne reflected: *It is not possible to be equally engaged in all activities in the community. You can be active in some activities and that have a more passive role in other activities.* This argument resonates with Wengers argument that diversity in community-members involvement is an important quality of mutual engagement.

TEACHER COLLABORATION ON DEVELOPING A COHERENT CURRICULUM IN PRIMARY SCIENCE

The primary science teachers and the principal agreed on that developing a local coherent curriculum in science within and between the departments was the primary objective of the development process.

This included that teachers' within the primary science teacher community started to collaborate about sharing best practice and developing new ways of teaching. But this shift from working individually to collaborating about planning and teaching was difficult, as can be seen in the following excerpt:

> Susanne: […] *it's an interplay. If I bring something, and sense that I get nothing in return, then the collaboration slowly seeps out. So collaboration is a question of equal engagement in some sense.*

Susanne argues that mutual engagement is important about developing the collaboration. Said in another way, lack of mutual engagement poses a constraint on developing collaborative activities.

Another example concerns her perception of collaborating with a science colleague in a micro-community:

> Susanne: *Regarding 6th grade. There Karen and I collaborate closely about planning and teaching in the two classes. Thus when Karen has taught about rocks, then she will come back and discuss what went well and what went bad […] that is, we have a much closer collaboration now about sharing practice. Because this is what we agreed on. It also means that we talk a lot more together now about teaching.*

Susanne emphasizes the quality of collaborating closely with a colleague about the teaching in primary science. Her collaboration with Karen focused both on assessing teaching, planning and developing new ways of teaching. In interviews and observations I found, that the teachers in general emphasized the interplay with other science colleagues in micro collaborative environments in their daily work.

What this means in relation to the objective of the developing the primary science teacher community as a whole, is that collaboration about sharing best practice and new ways of teaching must build on the teacher relations created in micro environments. Otherwise there is a risk that the collaborative processes cannot give meaning to the individual teachers own practice in primary science.

The joint effort of Peter and Susanne as community coordinators in the development process is crucial for this process to succeed. And they have to keep up the process over long time, because progress can be slow (McLaughlin & Talbert, 2006). But research has shown, that over time teachers come to see themselves as members of a professional community within the school (Stein, Silver, & Smith, 1998).

OUTCOME FOR TEACHERS AND STUDENTS

In the third phase of the NaTeKu-project, the teachers assessed how the development of collaborative activities affected their collective as well as individual practice.

In a group-interview the teachers and principal were asked to validate McLaughlin and Talberts' model as a diagnostic tool to assess the development of their community. Susanne argues that the model emphasizes the necessity to activate peripheral members to develop a shared responsibility and ownership towards the collective practice in the community:

> Susanne: *The model makes good sense in explaining the different roles people can have in different activities. It also emphasizes that active members in the community and the principal have to focus on activating peripheral members of the community. If some teachers tend to be peripheral in many activities it is difficult to develop a shared responsibility and ownership to the collective practice of the community.*

But both teachers and the principal agree that Susanne's point represents a minor problem because many teachers in the community are involved in diverse activities and they play different roles in various activities. The principal argues that there is a strong sense of shared responsibility and ownership in the community because most of the teachers play an active role in at least one of the various large scale collective activities. However, as the principal argues, activities that are initiated to improve to collective practice in the community have to be meaningful to each member otherwise there is a risk that the teachers engagement in sustaining the community becomes superficial. On the other hand the principal argues: *If the collective activities are important to each teacher's own practice, then the members might sense a strong connectedness to the culture in the community.* The principal's argument outlines an important criterion for developing collective activities within the community that makes sense in each individual members own practice.

Teacher's collaboration about developing a coherent curriculum is an example of an activity that stimulates the community members to sustain the community. In their final assessment community members concluded *that developing the coherent curriculum stimulated an increased responsibility towards the collective practice in the community*. They also argued that coherence in curriculum-activities between all departments has an impact on students learning outcome. Indications of this is that students transited from e.g. grade 6 to grade 7 act more competent in reflecting scientifically with procedural and declarative knowledge.

CONCLUDING REMARKS

The findings presented here show how the data provided the researchers with information about possibilities and constraints on developing collaborative work within a particular primary science teacher community.
This information is important to assess what actions to take to ensure success in achieving the objectives of a change process.
A summary of all the findings have been reported back to the school and the managing body of the project to help guide specific initiatives.
The framework of McLaughlin and Talbert's address many factors that are important to consider in changing the local science culture of a science teacher community. Data from this analysis will help to answer the research questions.

THE INFLUENCE OF PARENTS, TEACHERS, AND CELEBRITIES IN YOUNG PEOPLE'S CHOICE OF SCIENCE IN HIGHER EDUCATION

Jørgen Sjaastad

Department of Physics

University of Oslo, Norway

jorgen.sjaastad@matnat.uio.no

ABSTRACT

Science role models are often held up as one way to increase the recruitment to educations within science, technology, engineering, and mathematics (STEM). In a national survey in Norway, 5722 STEM students answered questions regarding *persons* and how they might have inspired and motivated a STEM related educational choice. *Parents* are proven essential. Results indicate that parents can inspire such a choice even without having education in STEM subjects themselves. Moreover, findings suggest that the father is the main source of inspiration. *Teachers* also come forth as important individuals. However, students in theoretical STEM educations highlight the influence of teachers more than students in applied STEM educations. *Publicly known people* are often suggested as influential science role models. However, most STEM students attribute famous people with a minor degree of influence for their educational choice. It is suggested that the influence of celebrities on Norwegian youth primarily is indirect, through defining which values and activities are associated with different STEM related careers. *Personal relationships* are essential in order to inspire and motivate STEM related educational choices. Initiatives taken to increase recruitment could benefit from not only having youth, but also those in personal relationships with youth as a target group.

Keywords: *Science role models; recruitment; parents; teachers; celebrities.*

INTRODUCTION

In Norway, as in many other Western countries, there is a lack of candidates with competence in science, technology, engineering, and mathematics (STEM). This fact is elaborated in different reports, e.g. *Europe needs more scientists!* (EU, 2004). To handle a growing population, increased consumption, and other economical, technological, and environmental challenges, it is essential that the work force holds necessary qualifications within STEM. Moreover, although not discussed in most political reports, educations within STEM can offer opportunities for self-development and joy. Both individual and societal needs can be met in these subjects.

Consequently, increasing attention is directed towards recruitment to STEM related educations. Science role models are among the frequently mentioned factors in such discussions. Most commonly, parents, teachers, and celebrities are highlighted as important. These three groups of people are, however, very different in the way they relate to youth.

Thus, actively making use of individuals to increase the recruitment of STEM students requires knowledge about the specific ways these people influence youth's attitudes towards STEM.

In the present paper we investigate to what degree parents, teachers, and publicly known people have inspired or motivated STEM students' educational choices. Furthermore, we discuss in what ways these persons influence youth for whom they function as *significant others*. Responses to a national survey in Norway will be analysed to achieve this.

THEORETICAL FRAMEWORK

Individualization is a prominent feature of Western modern cultures (Myers, 2002). One's identity is defined in terms of personal attributes and not so much in terms of the group one belongs to. For example, being considered an intellectual depends more on one's educational history than to whether or not one belongs to an "intellectual family". Moreover, individuals exercise a reflexive pattern in their development: The self-view is continuously revised based on the present external information. Through this reflexivity, the individual searches for self-realization. Self-realization in late modernity involves pursuing one's perceived "true identity" and the activities one finds meaningful (Giddens, 1991). This pursuit is no longer constrained by gender, family, or socio-economic background, or so it is perceived by youth. The modern constraint is given by *oneself:* One has to be true to one's self. Taconis and Kessels proposed that choosing science depends on students' individual fit to "science culture" (Taconis & Kessels, 2008). They identified a "gap" between pupils' self-image and their image of peers who preferred science. Many high school and college students consider science as difficult, uncreative, and socially isolating (Masnick, Stavros Valenti, Cox, & Osman, 2010). Being true to one's self disfavours a STEM related choice for those with a negative perception of science.

In this context science role models are valuable, since they display traits, patterns of behaviour, and meaningful ways to live and demonstrate how these can constitute a coherent self. The self and others does not exist as mutually exclusive social facts (Cooley, 1902). One hundred years ago, Cooley claimed that no consistent view of the self could describe it as distinct from other persons, and that every thought is some kind of response to influence from the surroundings. Today, we have an extensive amount of research describing in different ways how individuals comprehend each other. By observing and reflecting on other people's actions, traits, appearance, and reactions to the individual itself, the reflexive development is facilitated (see e.g. Bandura, 1977; Giddens, 1991; McClelland, 1951; Mead & Morris, 1934; Myers, 2002).

In particular, a person's attitudes are continuously influenced by the people on whom he depends (Mead & Morris, 1934). These people are in the tradition of Cooley and Mead commonly referred to as *significant others*. Woelfel and Haller describe the significant others as persons who exercise major influence over the attitudes of individuals (Woelfel & Haller, 1971). They have developed a framework to categorize the ways in which significant others contribute to the attitude formation process, and they make a distinction between definers and models. The *definers* hold expectations for the individual (1) by communicating definitions of the individual's self or (2) by communicating definitions of an object. An example of the first could be the parents who throughout their daughter's adolescence tell her that she is sympathetic and should be working with people. They could furthermore tell her about how science is a social activity, thereby communicating definitions of science as an object. The *models* influence attitudes (3) by displaying an example of an individual, as the geeky professor in the evening news exhibits one way to be a geologist, or (4) by displaying an example of an object, as the teacher guiding her students through a fascinating exercise of mathematics applied to water supply. Note that these four acts are not mutually exclusive. A particular significant other can contribute to the attitude formation process in different ways at the same time. A mathematics teacher can display interesting mathematics and play her role as a mathematician, and at the same time communicate to her students their traits and abilities, making her both a model and a definer.

Apparent from the previous paragraph, role models are in this context considered as a subgroup of significant others. Roles can be seen as clusters of norms, traits, and actions, which a person holding a specific social position can display in a given social setting (McClelland, 1951; Myers, 2002). A role model is then, strictly speaking, a person modelling a specific role, showing an example of a role one may choose to adopt (Gagné, 1985; Goffman, 1959). This way of defining a role model is primarily covered by the third category in the framework of Woelfel and Haller.

Two general results are of special interest for our discussion on how significant others influence attitudes towards STEM. Firstly, attitudes are rarely changed in one occurrence. The internalization of these involves a gradual transformation. To stimulate attitude change is much like trying to push a piano uphill: "It is not impossible, but one shove won't do it" (Myers, 2002). Attitude change takes continued effort. Secondly, the influence of a significant other might very well be subtle and non-conscious, unintended by both the individual and the significant other (Chartrand, Dalton, & Fitzsimons, 2006; Aarts, Gollwitzer, & Hassin, 2004). Aarts et al suggest, through six different studies, that individuals may automatically and without conscious awareness adopt and pursue goals implied by other people's behaviour.

METHOD

The results presented here stem from a national survey in Norway, administered in order to deepen the understanding of Norwegian youth's educational choices. Using paper-and-pencil questionnaires, data was collected from undergraduate students beginning STEM educations in August 2008. No sample was drawn; all educational institutions offering STEM educations were invited to collect data. Non-responses were mainly due to university or college administration not finding the opportunity to administer the questionnaire. We estimate that more than 95 % of students who actually received the questionnaire responded. Our respondents constitute more than 70 % of the total population of Norwegian first-year students within these subjects. 1/3 of the respondents are female, which is also representative for the population of STEM students. All data was collected during students' first week in university or college. The present study builds on responses from a sub-sample constituted by 5722 respondents studying mathematics, geosciences, informatics, physics, chemistry, biology, pharmacy, marine subjects, engineering, and graduate engineering.

The questionnaire was designed to give the students a chance to reflect upon their educational choice. It was constructed based on empirical findings and theoretical perspectives from previous research on young people's educational choices and their relationship to STEM (Angell, Guttersrud, Henriksen, & Isnes, 2004; Eccles (Parsons) et al., 1983; Eccles & Wigfield, 2002; Jacobs & Simpkins, 2006; Schreiner, 2006). The questionnaire was validated through hearings with the project reference group as well as a focus group with STEM students responding to the questionnaire pilot. Most questions were closed check-box questions with a 4-point Likert scale scored from 1–4. The two extremes were labelled, and for the question to be analysed here, labels were "to a minor degree" (1) and "to a major degree" (4):

> *To what degree have you been inspired or motivated for your educational choice by the following?*

The students were asked to answer this question considering five different groups of people, namely "teachers", "friends and/or sweetheart", "parents, step-parents and guardians", "siblings", and "other acquaintances". "Publicly known people in the media" appeared as an item later in the same question. For the present analysis, the Likert scale is treated as an interval scale, giving the opportunity to calculate mean scores. The analysis will focus on robust findings using the simple statistics of counting and mean scores.

In addition to the check-box questions, three open-ended questions were included in the questionnaire. Here, the respondents were invited to write about different aspects of their educational choice. In this article analyses will be done on these responses simply by counting which *persons* are mentioned.

RESULTS

The total of 5722 STEM students' responses is in favour of parents as sources of inspiration and motivation to a STEM related educational choice:

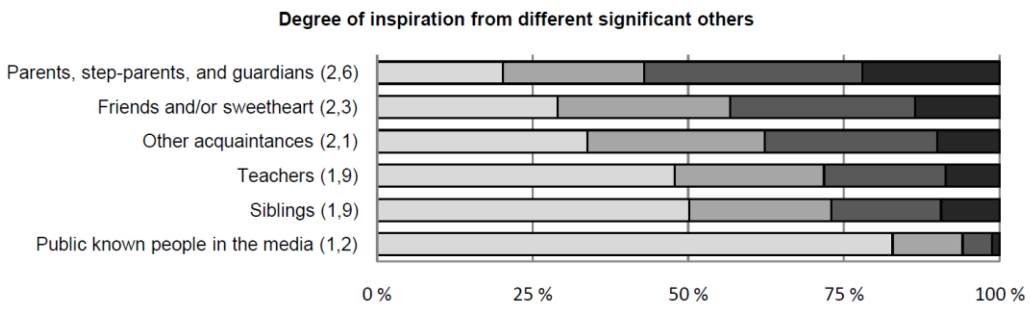

Figure 1. *"To what degree have you been inspired or motivated for your educational choice by the following?" Percentages in the four response categories from "to a minor degree" (light grey) to "to a major degree" (black). The groups are sorted by mean scores (in parentheses).*

PARENTS, STEP-PARENTS, AND GUARDIANS

Among the suggested significant others, STEM students rank parents as the most influential individuals for their educational choice. Parents are the only significant others with a mean score above the midpoint of 2,5. According to Figure 1, a total of 57 % of the students rank their parents in the top two categories.

In the questionnaire, the respondents were encouraged to answer some questions regarding their background. One of these concerned the educational background of their parents: "Does at least one of your parents/step-parents/guardians have education within mathematics, natural science or technology (e.g. engineering, technician, researcher, teacher in mathematics, biology, chemistry, physics, etc.)?" Of our 5722 STEM students, 48 % responded "yes", 48 % responded "no", and the remaining 4 % did not know. Splitting the students into these three groups yields the following regarding parents' influence on a STEM related educational choice:

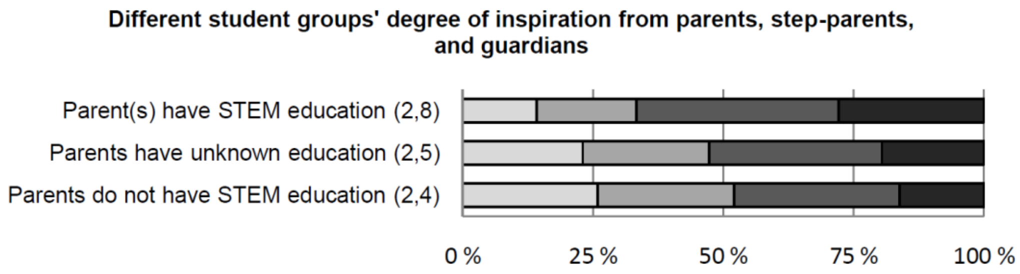

Figure 2. *"To what degree have you been inspired or motivated for your educational choice by the following?" Percentages in the four response categories from "to a minor degree" (light grey) to "to a major degree" (black). Student groups are sorted by mean scores (in parentheses).*

As displayed in Figure 2, there seem to be moderate differences between the students having STEM educated parent(s) and those who have not. However, among the students without STEM educated parents, 48 % still rank parents in the top two categories. Among all students claiming to be inspired and motivated to a major degree by their parents (Figure 1), 36 % report that their parents do not have an education within science, technology, engineering or mathematics. That is, parents do not need education within STEM to inspire a STEM related educational choice.

In the open-ended questions, parents are frequently mentioned. However, a great deal of these refers only to the father. Altogether, different versions of words referring to fathers are mentioned 216 times. The corresponding number of words referring to mothers is 45. This means that four out of five times a particular parent is reported to have inspired or motivated a STEM related educational choice, it concerns the father. Unfortunately, the question about parents' education does not distinguish between the mother's and the father's education. However, statistically we know that more men than women have a STEM education, which may be part of the explanation for fathers' dominance as sources of inspiration for STEM choices.

TEACHERS

The respondents rank teachers relatively low compared to parents, as seen in Figure 1. In the figure we see that a total of 48 % of the STEM students claim that teachers to a minor degree have inspired or motivated their educational choice. This seemingly low ranking is counterbalanced in the open-ended questions. Among the 5722 respondents, teachers are described 457 times. That is, 8 % of our respondents, and 25 % of those who mentioned persons in their descriptions, chose to write about one or several teachers when given a chance to reflect about their educational choice. This is the highest proportion received for any category of significant other.

The relatively low average score received by the teachers in the check-box question may hide interesting differences between subgroups. In fact, dividing the respondents into groups according to their specific choice of subject gives the following result:

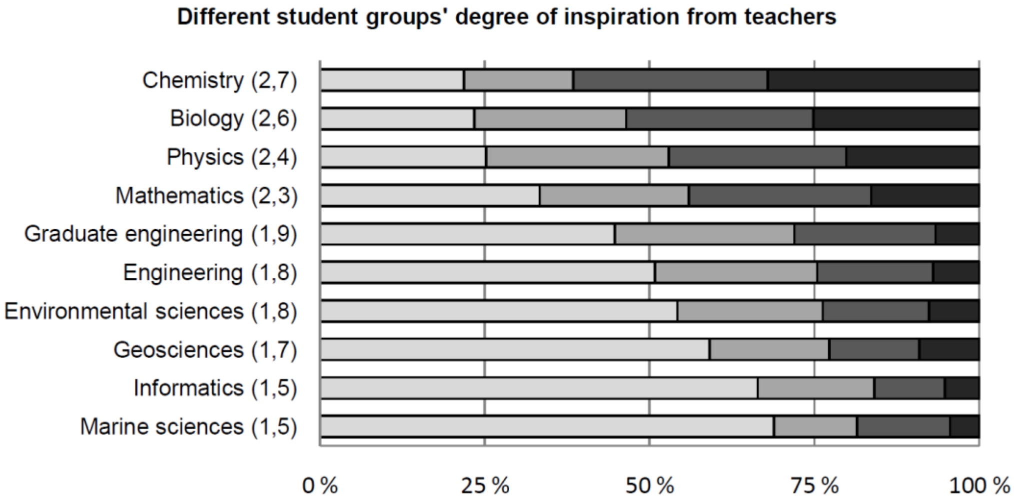

Figure 3. *"To what degree have you been inspired or motivated for your educational choice by the following?" Percentages in the four response categories from "to a minor degree" (light grey) to "to a major degree" (black). Student groups are sorted by mean scores (in parentheses).*

Respondents studying chemistry, biology, physics, and mathematics rank their teachers higher than do the students in other STEM subjects. These four subjects are strikingly similar to the science and mathematics discipline courses offered in upper secondary schools in Norway. Thus, it appears that teachers inspire and motivate more to traditional science and mathematics discipline subjects in higher education, and less to applied or technologically oriented STEM educations.

PUBLICLY KNOWN PEOPLE IN THE MEDIA

STEM students only attribute famous people with a minor degree of influence. As displayed in Figure 1, publicly known people in the media get a mean score of 1,2. A total of 83 % of the respondents claim that these people to a minor degree have inspired or motivated their educational choice. The 65 individual students claiming to be inspired by famous people to a major degree only total just above 1 %.

A related question in the questionnaire concerned films and TV series. The bioengineering students stand out from the other STEM students:

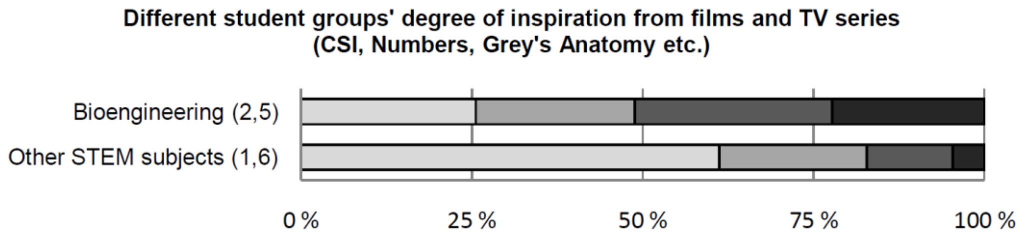

Figure 4. *"To what degree have you been inspired or motivated for your educational choice by the following?" Percentages in the four response categories from "to a minor degree" (light grey) to "to a major degree" (black). Student groups are sorted by mean scores (in parentheses).*

The first example of a TV series given in the questionnaire is CSI. CSI is short for "Crime Scene Investigation": Appealing crime technicians investigate and solve murder cases. In this TV series, bioengineering is used as a tool to reveal the truth. CSI is popular in Norway, and responses given in the open-ended questions confirm that a large proportion of the bioengineering students are indeed inspired by this particular TV series.

DISCUSSION

The present results will here be discussed in the framework of Woelfel and Haller, where the significant others operate as models and definers.

SIGNIFICANT OTHERS AS MODELS

Youth in Western modern countries have the freedom to choose among a wealth of educations and careers. However, it seems like despite individualization trends, young people often choose the *familiar*. STEM students rank their parents as most influential for their educational choice. In particular, fathers are highlighted. This could be due to the current gender imbalance in the Norwegian work force. Fathers are more commonly employed in STEM related professions; hence they can be models to a greater extent. The focus on fathers in the open-ended questions indicates this modeling effect and the fact that the familiar choice is a likely one. In some way, one can identify the same effect among those inspired by teachers and famous people. Those inspired by teachers often choose higher education within disciplines that correspond closely to the classical school subjects and more seldom within applied or technological fields. The few STEM students inspired by TV series also know, or at least hope to know, something about what they will do at work. Modeling is an important way to display which careers exist. Parents with STEM professions, teachers, and publicly known professionals can all be models both by modeling a particular role and by displaying the actual subject, thereby inspiring youngsters to make a choice of the familiar.

Publicly known people in the media are, however, attributed with a minimal degree of influence by the STEM students themselves. We cannot conclude from our results why this is. It could be that the Norwegian media picture does not hold enough science role models, or that the ones that do exist are uninspiring. Perhaps Norwegian youth is not susceptible to this kind of influence, or there might be some negative feelings associated with claiming to be influenced by celebrities ("everyone but me is fooled by commercials"). However, the fact that bioengineering students are inspired by the TV series CSI shows that models in the media can have a great effect. Moreover, the influence of significant others is often non-conscious. Different STEM related professionals might have been portrayed in the media without girls or boys using this information actively to make an educational choice. However, by this exposure the models contribute to which values and activities are associated with the particular STEM subject. These factors are essential in the reflexive process of self-realization, and the gap between youths' self-image and their image of those who practice science might be bridged.

SIGNIFICANT OTHERS AS DEFINERS

The high ranking of the parents is not only due to the modeling effect of fathers. In fact, the present results show that one does not need to have a STEM education to inspire a STEM related educational choice. Parents are in a special position to operate as definers. Long standing personal relationships are essential for the self-development of youth. Next to parents, friends are ranked highest among the significant others. Teachers are ranked low, but in the open-ended questions STEM students report how individual teachers have inspired their educational choices. Famous people are not reported to have had a major influence. Conclusively; it seems like the *personal relationships* are the key issue for recruitment of STEM students. Attitude change is a tedious process, and "one shove won't do it" (Myers, 2002). Lasting personal relationships give the opportunity to be a significant other. As definers, parents and friends can affect the way young people think both about themselves and about STEM, bridging the gap between young people and science from both sides. One does not need any STEM training to tell about the importance, usefulness, and joy offered by science, technology, engineering, and mathematics.

CONCLUSION

Parents are essential in the self-development of youth, given the opportunity to help young people define themselves. As definers, parents can also inform about issues related to STEM. Some parents, most commonly fathers, might furthermore have STEM training and can be models, displaying an example of a professional and displaying the subject itself. Teachers also have the opportunity to be both definers and models, due to the combination of personal relationships with pupils and their professional training. It is suggested that more applied STEM in Norwegian schooling can help teachers inspire to a wider range of STEM educations. Publicly known people are not proven essential for recruitment, although given the chance to be models. However, they might still influence educational choices indirect through their display of different STEM related careers. Conclusively, the present results indicate that initiatives taken to increase recruitment to STEM educations could be aimed not only directly at youth, but also at those in personal relationships with youth. Parents, teachers, and other "significant others" can help youth see themselves as STEM students and future professionals.

ABSTRACT

This study presents results from a questionnaire sent to 224 former science students from Nesna University College. One aim was to investigate to what extent they used teaching like fieldwork and active learning methods, when working as teachers. They were asked about their practice in the classroom and to what extent they wanted to change it. About 73% of the former students that answered were working as teachers and 58% and 96% of them have pupils doing fieldwork 1-3 times/year in primary and secondary school, respectively, while 47% and 77% respectively, wanted to do this more often. Few teachers let their pupils design/plan experiments in half of the lessons or more both in primary and secondary school, but as much as 71% and 83%, respectively, wanted to do this more often. This is in contrast to the amount of theory presented to the pupils where 52% and 76% of the teachers in primary and secondary school, claim to do it in half of the lessons or more, but only 5% and 8%, respectively, want to do this more often. Compared with other countries in OECD, Norwegian schools have few lessons in science, but experience an extensive curriculum and little time available to teach science under optimal conditions.

Keywords: *teaching, questionnaire, activity, teacher education, classroom*

INTRODUCTION

At Nesna University College, we have been giving specialized courses in science for teachers since 1978. We emphasize the use of active learning methods like fieldwork and performing of experiments in the classroom to achieve constructivistic thinking by the pupils, when educating teachers (Zoller et al., 1997). Learning by doing, discovery learning and inquiry-based learning are also variations of the fundamental thinking which are included in the term constructivism (Bruner, 1974, Imsen, 2005, Spronken-Smith et al., 2007). The courses aim to create an environment where the students participate actively in hands-on science activities and discussions to prepare them to create effective science learning environments for pupils in primary and secondary school. The relation between the science teacher education and the teaching practice in school has been studied by Andresen and Tveita (1993). We also use drama as a teaching method for our students, since studies have shown that drama can enhance and facilitate the understanding of both basic but also complicated concepts (Tveita, 1996, 1998, Ødegaard, 2003, Sarıçayır and Bayar, 2008). Visits to local industries and museums are also included in the science teacher education. It is important that the education prepares the teachers for the job in school and that the becoming teachers have had the opportunity to try out different activities during the education. It should therefore be easier to do the same activity together with pupils and the teacher should feel more comfortable in the teaching role. As teacher educators, we wanted to investigate to what extent the active learning methods in the education courses were adopted in the science classrooms and asked our former science students about what they did in the classroom in a questionnaire (Olsen et al., 2008, 2010).

MATERIALS AND METHODS

A questionnaire was sent out in February 2008 to all former science students having at least 30 sp (one half year full time study) in science in Nesna University College in the period from 1990 to 2007. The participation in the study was voluntary and the questionnaire was sent by mail. The questionnaire was sent to a total of 224 former students. To record the former students view on teaching practice in the classroom, they were asked to specify how often different kinds of teaching activities occurred. They could respond on a Likert scale of *Never 1, Some classes 2, About half of the classes 3,* and *Each or almost each class 4.* They were also asked weather they wanted to change their practice in the classrooms and they could answer *More seldom 1, No change 2* and *More often 3.* The incoming data was coded and entered in a SPSS datasheet. The respondants were treated anonymously and the data were analyzed with SPSS (version 17.0 for Windows) statistical program as described in Olsen et al., (2008 and 2010).

RESULTS

A total of 116 (52%) of the former students answered and returned the questionnaire. Of these, 85 (73%) former students were working or had been working as teachers, 38 (45%) of them were men and 47 (55%) were females. Of these, 47 were working in primary school with pupils from 1st to 7th grade and 26 were working in secondary school (8th to 10th grade). The rest of the teachers (12) were working in high school or had a job both in primary and in secondary school and they were therefore not included in this study.

Activity in the Classroom

The former science students (now teachers), seem to use active learning methods to a great extent in their teaching of pupils in primary and secondary school. The results from the investigation are presented in Table 1 and are compared to the Norwegian results in the TIMSS-2007 report (Martin et al., 2007).

Table 1. Percent of science teachers educated from Nesna University College report on what is going on in *half of the lessons or more* **in primary and in secondary school, compared to the "Teachers reports on Students doing Science Report" from Norway from the TIMSS-2007 study of pupils in 4th and 8th grade.**

Activities in the classroom	Primary-school	Secondary school	TIMSS-2007 4th grade*	TIMSS-2007 8th grade*
Pupils do experiments:	28	42	5	28
Teacher demonstrate experiments:	17	8	2	10
Work together in small groups on experiments and investigations:	44	40	7	30
Design or plan experiments and investigations:	11	12	3	14
Relate what students are learning in science to their daily lives:	56	65	42	54
Observe natural phenomena and describe what they see:	33	42	11	8
Teacher lecturing theory:	52	76	-	-

*Data from Martin et al., (2007).

The findings (Table 1) indicate that the teachers who have specialized in science from Nesna University College have much activity in the classroom, both in primary and in secondary school and that the pupils work in small groups doing scientific experiments or they observe natural phenomena and are allowed to describe and discuss what they see. However, 56% and 65 % of the teachers answer that they use half of the lesson or more on relating the science to the pupil`s daily life in primary and secondary school, respectively (Table 1). Presenting theory for the pupils in a lecture seemed to be an activity that is dominating both in primary and in secondary school and 52% and 76%, respectively, of the teachers do this half of the lesson or more (Table 1).

Drama and outdoor activities

The science teachers were asked how often they used drama and role play in science and how often they had their teaching outdoors. Both field work, outdoor teaching and drama in science are activities that we emphasize in the science courses at Nesna University College. The results are presented in Table 2. The teachers were allowed to answer *Never, 1-3 times/year, Every month* or *Every week* to these questions.

Table 2. Percentage of the science teachers educated from Nesna University College having drama and outdoor activities at different frequencies, when teaching in primary and secondary school.

	Primary school (n=45)				Secondary school (n=26)			
	Never	1-3 times/year	Every month	Every week	Never	1-3 times/year	Every month	Every week
Drama/Role play	30	59	9	2	25	71	4	0
Fieldwork/Excursion	6	58	26	8	0	96	4	0
Visit to museum e.g.	36	62	2	0	46	54	0	0
Outdoor teaching	9	30	26	35	42	46	8	4

These findings show that our teachers relatively often do outdoor activities, both in primary and in secondary school, but that the frequency decreases some in secondary school. As much as 70% and 75% of the teachers use drama and role playing in science 1 and 3 times each year or more often in primary and in secondary school, respectively. We also see that fieldwork and excursions are very common at school. In primary school 58% of the teachers work in the field with their pupils 1-3 times/year and as much as 26% do this every month. In secondary school 96% of the teachers work in the field or go on excursions with their pupils

1-3 times/year, but only 4% do this every month. Visits to museums, science centers or factories take place less often and 36% and 46% of the teachers never do this activity, but nevertheless 62% and 54% of the teachers in primary and secondary school, respectively, claim to do it 1-3 times/year (Table 2).

The wish to change teaching practice

We also looked into to what extent the science teachers educated from Nesna University College wanted to change their teaching practice. The result from the questionnaire is presented in Table 3 and shows in which direction the teachers wanted to change their practice in primary and in secondary school.

Table 3. Percent of science teachers educated from Nesna University College that want to change their teaching practice in primary school (1st-7th grade) and in secondary school (8th-10th grade).

	Primary school (n=43)			Secondary school (n=23)		
Activities in the classroom	**More seldom**	**No change**	**More often**	**More seldom**	**No change**	**More often**
Pupils do experiments:	0	37	63	0	46	54
Teacher demonstrate experiments:	2	60	38	0	61	39
Work together in small groups:	0	55	45	0	61	39
Design or plan experiments and investigations:	0	29	71	0	17	83
Relate what students are learning in science to their daily lives:	0	70	30	0	58	42
Observe natural phenomena and describe what they see:	0	67	33	0	58	42
Drama/role playing:	0	51	49	0	36	64
Fieldwork/Excursions:	2	51	47	0	23	77
Visits to museums and factories:	0	19	81	0	32	68
The teacher gives a lection:	2	93	5	4	88	8

The results presented in Table 3 show that the science teachers wanted to increase the amount of pupil-activities in the classroom, both in primary and in secondary school. More than 50 % of the teachers answered that they wanted to let the pupils do more experiments, let them design and plan experiments and investigations and go to visit museums and factories more often, in primary school. In primary school, the teachers seemed to be satisfied with the way science was related to the pupils daily lives (70%), with the amount of experiments that were demonstrated (60%) and with the amount of theory that was presented to the pupils (93%) (Table 3). In secondary school, more than 50% of the teachers wanted their pupils to do more experiments, design and plan experiments and investigations, do more fieldwork and visit museums and factories more often. These teachers were satisfied with the amount of experiments demonstrated for the pupils (61%), with the organization of the class in small groups (61%) and with the amount of theory presented (88%) (Table 3). Presenting theory was the only activity the teachers, both in primary and in secondary school, not wanted to do more. Only 5% and 8 % of the teachers in primary and secondary school, respectively, answered that they wanted to do this activity more often (Table 3), but only 2% and 4% reported that they wanted to do the activity more seldom.

DISCUSSION

Results from TALIS (Teaching and Learning International Survey, (Vibe et al., 2009).) showed that the majority of secondary grade teachers in all participating countries (OECD) were females and that Norway was among the countries with the highest proportion of male teachers (40%). This reflected our survey where 45% of the science teachers were males.

However, Olsen et al., (2010) found that the teachers goals with their science teaching and hence, their teaching practice, seemed to be independent of gender.

Findings shown in Table 1 indicated that the science teachers educated from Nesna University College had a high degree of pupil-activity in their lessons. Compared with the results from Norway in the TIMSS-2007 International Science Report on: “Teachers` reports on students doing science investigations” where the numbers reflects “percentage of students whose teachers reported students doing the activity about half of the lesson or more”, our former students seemed to have more activity in the science classroom (Table 1), (Martin et al., 2007). However, this could partly be due to the fact that our numbers, especially in primary school, reflected the activity in the classroom from 1st to 7th grade and it is likely that there is more activity in the lowest grades and that this percentage therefore is considerably higher than the numbers from the TIMSS report. Our former students seemed to have less activity in secondary school (8th-10th grade), especially in the activities: “Teacher demonstrates experiments” and that the pupils to a smaller extent than the 8th grade teachers in the TIMSS study, are allowed to “Design or plan experiments and investigations” (Table 1). However, as indicated in Table 3, 39% and 83%, respectively, of the teachers in our study, claim that they want to do these activities more often in secondary school.

Also activities like field work, drama and going on excursions to e.g. museums and science centers seemed to be activities that our teachers wanted to do more of, both in primary and in secondary school (Table 3). However, they seemed to be satisfied with the amount of new theory that must be introduced to the pupils and they did not want to do this activity more often (Table 3). They were also satisfied with the way they relate what students are learning in science to their daily lives (Table 3). Table 3, shows that a majority of the teachers wanted to have more activity in the classroom, but Table 1 show that they already had a lot of activities in science compared to other teachers in Norway. Ellingsen et al., (2010) have in their study tried to find out why the science teachers want to have so much activity and what hinder them in having more activity.

Results from UNESCO show that Norway compared to other countries gives much less time for teaching in science (Sjøberg,1992). This has almost not changed in later years. Almost all the teachers in our questionnaire answered that it was enough theory in science, only 5% and 8% wanted to teach theory more often in primary school and secondary school, respectively, but most of the teachers wanted to do more activities, demonstrations and experiments (Table 3). Results from the PISA (Programme for International Student Assessment) project run by the OECD (Organization for Economic Cooperation and Development) show that Norwegian pupils seem to score low in natural science compared to other OECD countries (Kjærnsli et al., 2007). The score of more than 20% of the pupils is below or at level 1 and only 23% of the pupils score at or above level 4 in Norway compared to 18% and 28% below or at level 1 and above level 4, respectively, in the OECD countries (Kjærnsli et al., 2007). The TIMSS 2007 International Science Report shows an average of 8% and 11% science instructional time of total instructional time implemented in the school in the 4th grade and 8th grade, respectively for all countries in the investigation. For Norway, the numbers were lower; 5% and 10% of total instructional time at school were used on science in 4th grade 8th grade, respectively (Martin et al., 2007). Our results show that the former science students use active learning methods when working as teachers, and that they define science as a practical topic. It seems like our science courses, to a high degree, are reflected in the science classrooms. However, the amount of theory in science is high in primary and secondary school. With few lessons in science on the schedule, the teachers have to make priorities and it seems like they focus on working through the curriculum, even though their wish is to do more activities. The teachers are faithful to the curriculum and want to secure that they will go through everything with their pupils, but if there is any spear time, they add activities that will enhance the pupils understanding of science.

ACKNOWLEDGEMENTS

Thanks to our Master student Joachim Einmo who coded and entered much of the incoming data in a SPSS datasheet.

WHY IS IT HOTTER IN SUMMER THAN IN WINTER? K-5 STUDENTS' & PRE-SERVICE ELEMENTARY TEACHERS' CONCEPTIONS OF SEASONAL CHANGE

Ioannis Starakis

ABSTRACT

In the present study, primary school students' and pre-service teachers' ideas of Seasonal Change, are investigated. The research was carried out in nine primary schools of Athens and in the Primary Education Department of the University of Athens. Written reports were used for gathering data while students had also the opportunity to support their answers with drawings. The results showed the following:

1) Pre-service teachers address notions which involve the movement of the Sun and/or the Earth while primary school students address human centered, tautological and phenomenological notions as well.
2) Both primary school students and pre-service teachers adopt mainly two Schemes of explanations; alterations in the distance between the Sun and the Earth and alterations in the Earth–Sun relative orientation/illumination.

Keywords: *K-5 students, Pre-service teachers, Sun-Earth-Moon system, Seasonal Change.*

1. INTRODUCTION

In the past three decades many researchers have examined children's and adults' ideas of basic astronomical events (see Bailey & Slater 2004). Some of these studies concerned Seasonal Change (Baxter 1989, Mant & Summers 1993, Sharp 1996, Atwood & Atwood 1996, Galili & Lavrik 1998, Parker & Heywood 1998, Trumper 2001, Frede 2006, Hsy 2008).

The most common results that can be extracted from these studies are:

- Young students address notions which involve near and familiar objects/phenomena (clouds, day length, weather phenomena, etcetera).
- As they get older they replace them with others which involve the movement of the Sun and/or the Earth.
- The most common notion is the one which attributes Seasonal Change to the variations in the distance between the Sun and the Earth (Baxter 1989).

However, in many cases, significant deviations are recorded among certain studies, either in the percentages or the existence of a notion itself, without any further justifications. For example, while in Baxter's (1989) and Trumper's (2001) studies, a high percentage of 15-16 year old students attributed Seasonal Change to the inclination of the Earth's spinning axis (around 50%), the corresponding percentage in Galili's & Lavrik's (1998) study was just 20%.

The present study is part of a broader research concerning the Sun-Earth-Moon system from an educational point of view and is based on the “Model of Educational Reconstruction”. In this model the understanding of students’ perspectives and the interpretation of the scientific content, are closely linked, aiming at designing new teaching and learning sequences (Duit et. al. 2005).

Consequently our study focuses on addressing and comparing Seasonal Changes’ conceptions of students in Greece who have never been taught the phenomenon before (k-5 students) with conceptions of students who have been taught it twice (pre-service elementary teachers), not as a means of exploring obstacles of learning but as points to start from and mental instruments to work with in further learning (Duit & Treagust 2003).

2. SEASONS (THE SCIENTIFIC MODEL)

The Earth’s spinning axis is not vertical to its revolution level around the Sun, but it forms a $23{,}5^o$ inclination, pointing always to the Polar Star. The combination of the Earth’s inclination and revolution around the Sun, results in Seasonal Change. Specifically, during the Earth’s revolution around the Sun, the hemisphere leaning towards the Sun is exposed to solar radiation more than the other since solar radiation prostrates more vertically to this hemisphere.

3. SEASONAL CHANGE IN GREEK CURRICULUM

In the Greek educational system, Seasons are taught either in elementary (6^{th} grade) or in high school (7^{th} grade) in Geography. The concerned textbooks present the scientific knowledge of the phenomenon ‘in black and white’, accompanied by explanatory figures. It has to be mentioned that students’ conceptions are not taken into account in these textbooks.

4. PRESENT STUDY

The present study took place: a) in nine primary schools of Athens, from different socioeconomic regions, with a sample of one-hundred and forty-two (142) 5^{th} grade students and b) in the Primary Education Department of the University of Athens, also with a sample of one-hundred and forty-two (142) undergraduate elementary pre-service teachers. Each of the participants had approximately 15 minutes to answer the following question in writing:
“*Why is it hotter in Summer than in Winter? How do you explain Seasonal Change on Earth?*”
Apart from giving a written response, both k-5 students and pre-service teachers had to support their answers with drawings. Two students and one pre-service teacher did not answer the question.

5. RESULTS

5.1 THEORETICAL FRAMEWORK

The answers of the participants were categorized according to a two-level hierarchical structure proposed by Galili (1995). According to this model of categorization, several seemingly different explanations (**Facets of knowledge**) may be expressed. However, they can share a common explanatory mechanism (**Schemes of knowledge**). For example, the notions that *“Seasonal Change is caused by alteration in the distance between the Sun and the Earth, due to Earth’s elliptic orbit around the Sun”* and *“Seasonal Change is caused by* *alterations in the distance between the Earth's north and south hemisphere with the Sun, due to the Earth's tilt of its spinning axis*" are two different Facets of the same Scheme (*alteration in the distance between the Sun and the Earth*) .

5.2 SCHEMES

So, according to both k-5 students and pre-service teachers, responses, the following Schemes were identified:

1. Angle of sun rays incidence on Earth
   *(*For example: *In Summer, sun rays prostrate on Earth more vertically than in Winter)*
2. Alteration in the Earth-Sun relative orientation/illumination
   *(*For example: *As the Earth spins, the part that 'sees' the Sun has Summer and the other part has Winter)*
3. Alteration in the distance between the Sun and the Earth
   *(*For example: *In Summer, the Earth comes closer to the Sun, while in Winter the opposite happens)*
4. Mixed (combinations of 1,2 and 3 schemes)
   (For example: As *the Earth follows its elliptic orbit around the Sun, it sometimes goes further away, compared to other points of the orbit. This is when we have winter. This also has to do with the Earth's spinning. When certain places of Earth don't 'look at' the Sun, these places have also winter.)*
5. Phenomenological notions
   *(*For example: *Clouds block Sun rays in Winter)*
6. Human centered notions
   *(*For example: *If there was no Summer, we wouldn't go on vacation)*
7. Tautological Notions
   *(*For example: *In Summer the temperature is high)*
8. Not classified Notions
   *(*For example: *God created the Seasons)*
9. Fragmented Notions
   *(*For example: *The Seasons change because the Earth orbits the Sun)*

Table 1 presents the frequency of answers of each Scheme and each population of the sample, while Figure 1 presents the corresponding percentages.

Table 1: Frequency of answers of each Scheme and each population of the sample

(SCHEME)	Number of K-5 Students	Number of Pre-service Teachers
1. Angle of sun rays incidence on the Earth	1	17
2. Alteration in the Earth-Sun relative orientation/illumination	33	21
3. Alteration in the distance between the Sun and the Earth	26	62
4. Mixed (combinations of 1,2 and 3 schemes)	0	6
5. Phenomenological Notions	21	4
6. Human centered Notions	21	5
7. Tautological Notions	8	0
8. Not classified Notions	8	3
9. Fragmented Notions	22	23
Total	N=140	N=141

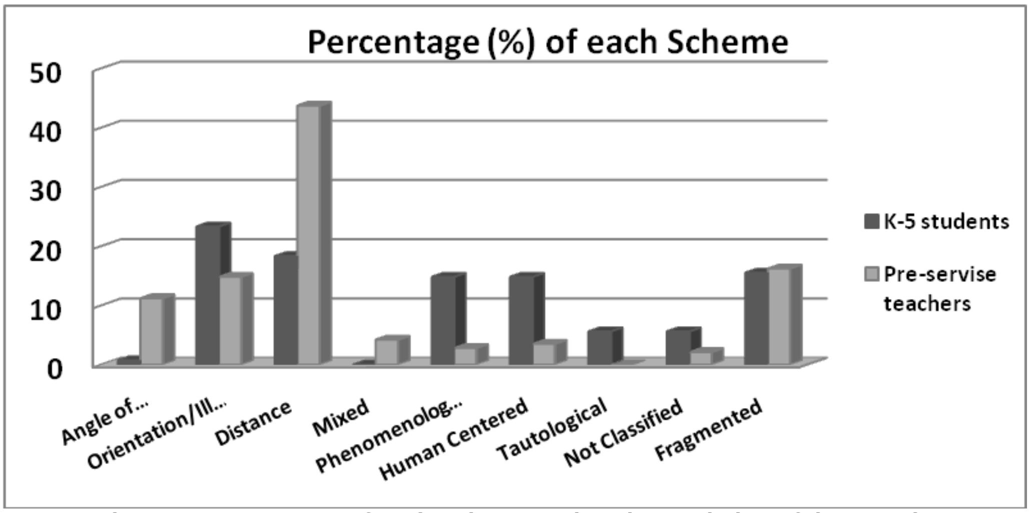

Figure 1: Percentage of each Scheme and each population of the sample

5.3 DATA ANALYSIS

5.3.1 Angle of sun rays incidence on the Earth

Only one k-5 student (0,7 %) used this causal mechanism in his reply, being at the same time far from the scientific model. This student wrote:

> *In Winter the Sun goes under the Earth and hits it sideways with its rays, while in Summer the Sun comes in front of the Earth and hits it vertically with its rays …*

This was a presumable result since k-5 students: i) have never been taught the phenomenon before ii) their everyday experience couldn't lead them to the adoption of such ideas.
Regarding pre-service teachers, the corresponding percentage (11,2%) was not high, bearing in mind that they have been taught the phenomenon twice. Among these university students (N=17), only one came close to the scientific explanation. The rest either just mentioned "The angle of Sun rays incidence on Earth", without any further explanation:

> *During Summer sun rays strike the Earth vertically. In Winter, sideways…*

or tried to combine unsuccessfully and not thoroughly this causal mechanism with the Earth's rotation around the Sun:

> *As the Earth orbits the Sun, in Summer sun rays strike more vertically in certain places while in Winter they strike sideways…*

5.3.2 Alteration in the Earth-Sun relative orientation/illumination

A number of k-5 students (N=33 or 23,3%) and pre-service teachers (N=21 or 14,8%) adopted the second Scheme, according to which, when a place of Earth is orientated towards the Sun it "receives" more sun rays and has Summer, compared to the places which "receive" less or no sun rays and have Winter. It seems that students who have adopted this Scheme of Knowledge confuse the causal mechanism of Seasonal Change with the one of Day and Night Cycle.

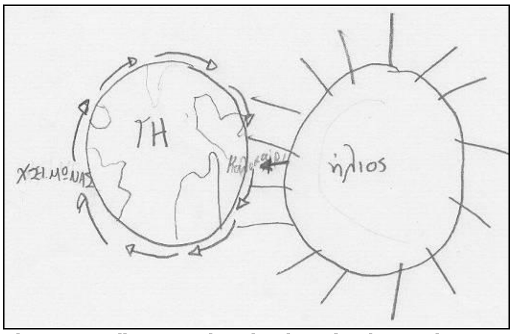
This Scheme, according to both k-5 students' and pre-service teachers' responses, manifested itself in five Facets (table 2). Each of them linked the alterations in the Earth–Sun relative orientation to the following movements:
a) The Earth's spinning (figure 2a),
b) The Earth's revolution around the Sun,
c) A combination of 'a' and 'b',
d) The Sun's revolution around the Earth
e) The Sun moving across the North and South hemispheres of the Earth.

There were also some cases where respondents just addressed the parameter of orientation without stating how this orientation changes. For example, one pre-service teacher wrote:

It has to do with the Earth's position compared to the Sun. When the Sun illuminates a certain place of the Earth, this place has Summer. The opposite place is not illuminated. This place has Winter. (figure 2b)

Table 2: Frequency of answers of each Facet within Orientation / Illumination Scheme

FACETS WITHIN ORIENTATION/ILLUMINATION SCHEME	Number of K-5 Students	Number of Pre-service Teachers
a) Earth orbits Sun	9	8
b) Earth spins	11	2
c) Earth rotates around Sun and spins	2	4
d) Sun rotates around Earth	2	2
e) Sun moves across north and south hemisphere of Earth	1	0
f) No further explanation provided	4	4
g) Fragmented explanation	4	1
Total	N=33	N=21



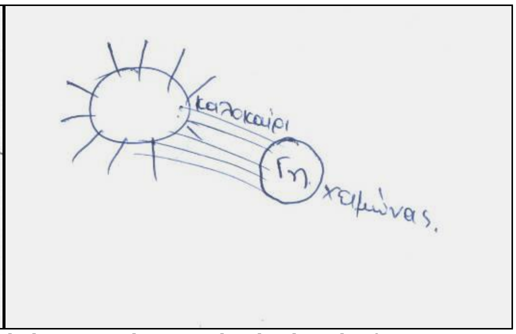


Figure 2a (k-5 student's drawing) Figure 2b (pre-service teacher's drawing)
In Greek "Καλοκαίρι" means "Summer" and "Χειμώνας" means "Winter".

Data analysis revealed a relative decrease in the corresponding percentages, from k-5 students to pre-service teachers. This decrease regards mostly Facet "b" which ascribes periodic alteration in the Earth-Sun relative orientation, to the Earth's spinning (N=11 for k-5 students, N=2 for pre-service teachers). This is consistent with the findings of bibliography, according to which as students get older, they adopt the scientific model of Day and Night Cycle in higher percentages (Baxter 1989). Hence, one could assume that pre-service teachers confront themselves cognitively if they try to use the same movement of the Earth (spinning) and the same causal mechanism (illumination of the Earth from the Sun) in order to explain two completely different phenomena (Day-Night Cycle, Seasons). A typical example of such a confrontation is the written answer of one of the two pre-service teachers who displayed Facet "b":

The Earth spins (but I am not sure if this spinning lasts one day or one year). Anyway, I would answer, that because the Earth spins around its axis, each season, the Sun illuminates us or not… If so, then what happens with day and night?

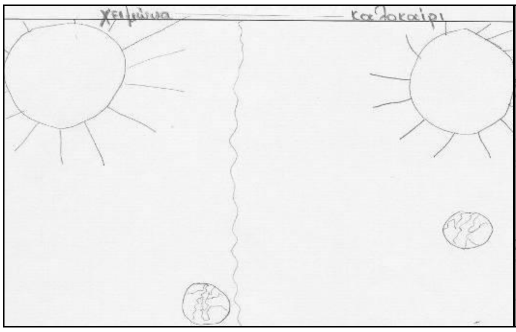
On the contrary, when the chosen movement differs from the one which explains the Day-Night Cycle (see Facets a, c, d, and e), there is not such a confrontation, as shown in the results. For example, one pre-service teacher, holding Facet "d", wrote:

According to the Sun's revolution around Earth, 3 months per year the Sun "illuminates" and warms a certain part of the Earth (Summer)...At the same time theSun doesn't "illuminate" the opposite part of the Earth (Winter).

5.3.3 Alteration in the distance between the Sun and the Earth

The basic root of this Scheme seems to be the everyday experience, according to which, the closer we come to a source of heat the warmer we feel (Halkia 2006). It is worth, however, stating that data analysis revealed a considerable increase of the corresponding percentages, from k-5 students (N=26 or 18,3%) to pre-service teachers (N=62 or 43,7%). Moreover, while k-5 students' highest frequency Facet of this Scheme (14 out of 26) refers to the simple statement that the Earth approaches and goes away from the Sun or vice versa (figures 3a, 3b):

> *When the Earth is close to the Sun we have Summer. When the Earth goes away from the Sun, Winter is coming…*



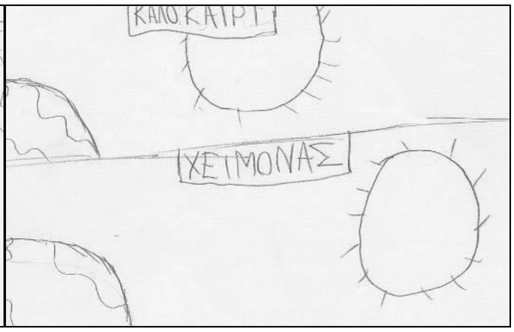


Figure 3a **Figure 3b**
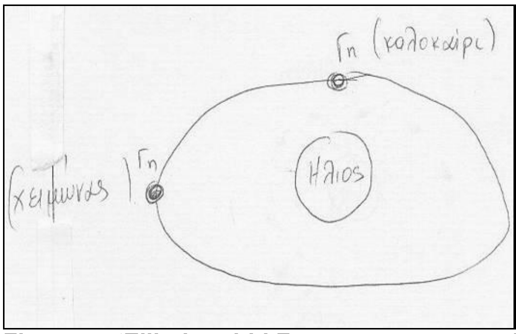
(both are k-5 students' drawings)
In Greek "Καλοκαίρι" means "Summer" and "Χειμώνας" means "Winter".

Pre-service teachers' highest frequency Facet (27 out of 62) refers to the periodic variation in the distance between the Sun and the Earth, due to the Earth's elliptic orbit around Sun (figure 4a). One pre-service teacher explained:

> *Because the Earth's orbit is elliptic…Therefore, when it approaches the Sun we have Summer and when it is far from the Sun, Winter.*

Another Facet within this Scheme (only pre-service teachers displayed it) connects the Earth's tilt of its spinning axis with the variation in the distance between the Earth's north and south hemispheres from the Sun (figure 4b). There were seven (7) pre-service teachers (4,9 %) who held this Facet:

> *Because the Earth has a tilt. So, when the north hemisphere is near the Sun it has Summer and when it is far from Sun it has Winter.*



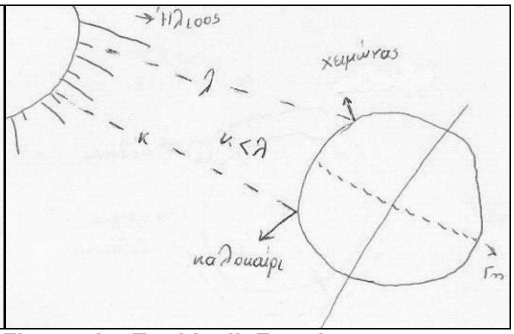


Figure 4a 'Elliptic orbit' Facet **Figure 4b: 'Earth's tilt Facet'**
(both are pre-service teachers' drawings)
In Greek "Καλοκαίρι" means "Summer" and "Χειμώνας" means "Winter".

There were also some replies in the context of "distance" dependence Scheme, either from k-5 students (N=5 or 3,5%) or from pre-service teachers (N=14 or 9,8%), which have never been recorded before on related bibliography. According to these responses, when a place on the Earth is orientated towards the Sun it has Summer since it is closer to the Sun than an opposite situated place. One pre-service teacher explained:

> *Because in Summer the part of the Earth where we stand is closer to the Sun, so it gets warmer. On the contrary, in Winter the same part is far away from the Sun, so it gets colder…*

(Figure 5 corresponds to the pre-service teacher who gave the above answer)

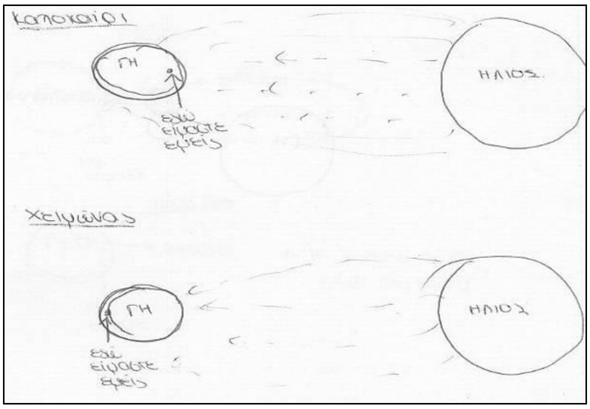

Figure 5 (pre-service teacher's drawing)
In Greek "Καλοκαίρι" means "Summer" and "Χειμώνας" means "Winter".

Given that teaching Seasonal Change in the Greek educational system does not step on the '*dissatisfaction with existing conceptions*' (Posner et. al 1982), it seems that, as time goes by, students incorporate declarative aspects of scientific knowledge (*elliptic orbit, tilt of the rotational axis, etcetera)* into the aforementioned "*distance"* dependence Scheme.

5.3.4 Mixed (combinations of 1, 2 and 3 schemes)
Only very few pre-service teachers (N=6 or 4,2%) gave responses within this Scheme. They tried to combine "*distance"* dependence Scheme either with '*angle incidence*' or with "orientation/illumination" dependence Schemes, resulting mostly in incoherent outcomes:

> *When we have Summer in Greece, sun rays strike vertically. At the same time the Earth is closer to the Sun due to the elliptic orbit around the Sun…*

5.3.5. Phenomenological Notions
K-5 students in a percentage of 14,8% (N=21) attributed Seasonal Change to : a) weather phenomena (snowing, sun shining e.t.c), b) clouds as obstacles for sun rays' propagation, c) warm and cold air-streams, d) day length and e) the change of the Sun's position on the horizon, during the year. In other words, they made use of everyday experienced objects and phenomena. The corresponding percentage for pre-service teachers is minimized (2,8% or N=4).

5.3.6 Human centered Notions
As far as the percentages of this Scheme are concerned, the picture is analogous to the previous one. Twenty-one (21) k-5 students (14,8%) related Seasonal change to human needs:

> *Because people can't survive only with cold, they need heat as well…*

That happens because we must swim in Summer... play with snow in Winter ... all kinds of flowers must blossom in Spring and make our city beautiful.

On the other hand, only 5 pre-service teachers (3,5%) adopted this Scheme:

In order to be able to adapt to all temperatures…

5.3.7. Tautological Notions

Only few k-5 students (N=8 or 5,6%) gave responses within this Scheme by reproducing the content of the question they were given:

…As time passes, seasons change. It is hot in Summer and it is cold in Winter. That is to say that for every season we have a different temperature.

5.3.8. Not classified Notions

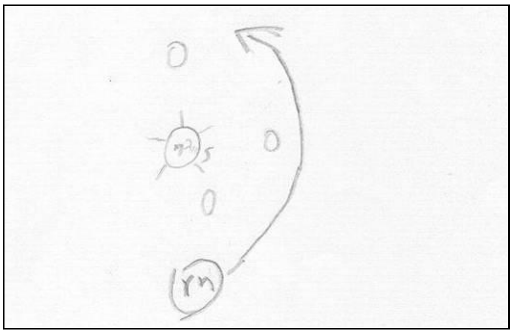
Some explanations (*God's will, hot and cold planets, natural warming and freezing of the Earth, molecules' movement, etcetera)* either from k-5 students (5,6% or N=8) or from pre-service teachers (2,1 % or N=3) could not fit to any of all the aforementioned Schemes and could not form distinguishable Schemes owing to their small number.

5.3.9. Fragmented Notions

Finally, twenty-two (22) k-5 students (15,5%) and twenty-three (23) pre-service teachers (16,2%) gave answers which either i) did not make any sense or ii) did not include any causal mechanism for Seasonal Change. Answers of category 'ii' just involved celestial movements (The *Earth's spinning, the Earth's revolution around the Sun, a combination of the two aforementioned movements, the Sun's revolution around the Earth*) *or* the tilt of the Earth's rotational axis:

As the Earth rotates around Sun, the weather changes…

(Figure 6a corresponds to the k-5 student who gave the above answer)
Seasonal change is owed to the Earth's tilt...
(Figure 6b corresponds to the pre-service teacher who gave the above answer)



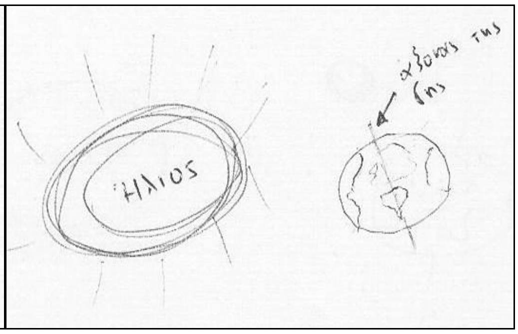


Figure 6a (k-5 student's drawing) **Figure 6b(pre-service teacher's drawing)**

Unlike other studies (Baxter 1989, Atwood & Atwood 1996, Galili & Lavrik 1998), the present study did not classify such answers to specific categories because, according to the model of categorization we followed, there was no accounting for why these movements or the Earth's tilt affect seasonal change.

6. CONCLUSIONS

Four basic conclusions could be drawn from the data analysis of our research concerning k-5 students' and pre-service teachers' conceptions of Seasonal Change:

1. Confirming previous studies (Baxter 1989), is seems that, as time goes by, children move from a) human centered, b) tautological and c) phenomenological notions to notions which involve Sun and/or Earth movements.

2. Despite the fact that pre-service teachers, unlike k-5 students, have been taught about Seasonal Change twice (both *in elementary and in high school*), very few of them adopt the '*Angle of sun rays incidence on Earth*' Scheme. The results showed that pre-service teachers, within this Scheme, cannot present a coherent explanation of the Seasonal Change. They only reproduce pieces of scientific information in a piecemeal fashion.

3. Both k-5 students and pre-service teachers adopt mainly: a) "Alteration in the distance between the Sun and the Earth" and b) "Alteration in the Earth-Sun relative orientation/illumination" as seasonal change's causal mechanisms. Regarding the "Alteration in the distance between the Sun and the Earth" Scheme, a considerable increase in related percentages, from k-5 students to pre-service teachers, takes place. This is mainly because, as time passes after having been taught at school, students "embody" in this Scheme all parts of scientific knowledge *(Earth's elliptic orbit around Sun* and *Tilt of Earth's rotational axis)* that can be assimilated, while they "reject" that part which cannot assimilated *(Angle of Sun rays incidence)*. That is consistent with previous studies on how students embody the culturally accepted views to their initial models (Vosniadou & Brewer 1994). As regards the "Alteration in the Earth-Sun relative orientation/illumination" Scheme, it seems resistant to change as long as it is not confronted with the scientific explanation of the Day and Night Cycle.

4. Conclusions 2 and 3 lead us to the final conclusion that teaching of Seasonal Change in school should step *firstly* on the dissatisfaction with students' initial Schemes and *secondly* on activities aiming at explaining why a different angle of the sun rays' incidence results in a difference in the Sun's radiation received.

ABSTRACT

This study refers to the research conducted with primary school students examining whether they can identify the ‘scientific context’ through analyzing science fiction short stories involving extraterrestrial intelligence. In addition, we examine whether they can write science fiction stories of their own using scientific elements in order to make their stories plausible. The research was conducted with a sixth-grade primary school class of 30 students over a period of five weeks in two-hour sessions during which students read and analyzed science fiction short stories and wrote science fiction stories of their own.

Our data (worksheets and science fiction stories by the students) were analyzed with Qualitative Content Analysis. Our analysis shows that the students are able to identify the elements of the text referring to the ‘scientific context’ and associate them with the literary context of the stories. However, the students find it difficult to integrate ‘scientific context’ in their own stories.

Keywords: *science fiction, extraterrestrial intelligence, science education*

INTRODUCTION

In this world transformed by technological, economic, and ecological changes, the role of literary culture seems more important than ever. This is a fact that is recognised as an imperative in the field of Science Education, as recent decades have seen an increase in sociocultural perspectives within Science and Environmental Education that are reflective of the cultural turn in intellectual theory more generally. These critical, historical, political, and socioecological views, interested in access to scientific knowledge, education, and power, have become part of enlightened Science and Environmental Education discourses (Carter, 2008). In this perspective, the gap between the sciences and the humanities and the urgent need to confront it, do not exist on the theoretical level alone. Indeed, we face an increasing number of situations that Bruno Latour, variously describes as ‘borderline’ questions or ‘sociotechnical’ and ‘ethicoscientific’ imbroglios (Latour, 2003). These are intricately woven mixes that pertain simultaneously to the domains of the natural sciences and the humanities. Therefore, a sort of composite sciences-humanities literacy is required to help a democratic citizenry not only to scrutinize but also to contribute to science-and technology-based decisions about such imbroglios.

One way of investigating into these issues is through the literature of science fiction. With the genre's license to create new societies and worlds, it seems an ideal tool with which to explore socio-scientific alternatives. Moreover, as science fiction is so often taken to be the expression of political opinion or ideology of the scientific and technological society aimed at presenting alternatives to social condition, it functions as thought experiment and critical discourse which can also bring more skepticism about politics, ideologies and epistemological certainties in the context of Science Education (Gough, 2006, Weinstein, 2006).

Science fiction is an 'incubator' for imaginative minds to create visions that help us to glimpse not only the scientific present and future, but also something about ourselves, and functions as the integrator of socio-cultural space that supports the dialogue between science and humanities. Yet more, science fiction is a genre well-suited to express the concerns about environment and explore humanity's place in ecological systems since it encompasses a broad range of issues that derive from the interaction of humans with the natural word, and this literary genre's articulations contribute significantly to the broad rethinking of the relations between human and nature that is currently taking place specially in western societies (Merrick, 2005).

To bring science fiction into the science classroom is a way of "cross- fertilizing" the disciplines; yet these are precisely the sorts of things that can and should be done to open our students to broader intellectual perspectives. In reality, there is a great deal of overlap between the disciplines. The common thread that holds imaginative works and scientific works together is a celebration of the sense of wonder and awe that comes with addressing big questions about the nature of humankind and the universe our species inhabits (Brake *et al,*2006).

Science fiction as creative and innovative literary genre addresses complex questions about our role in the cosmos which is both cross-curricular and invigorating, demanding a widening knowledge of various disciplines, drawing together the disparate strands of science and the humanities, and generating application to our modern world and its broadening horizons (Griffiths, 2009). Science fiction narratives (stories) are considered as highly valuable resources for Science Education (Negrete, 2003). Negrete and Lartigue (2004) suggest that narratives are indeed an alternative and an important means for science communication to convey information in an attractive, imaginative and memorable way. To present scientific information through stories should be regarded as an important means to transmit information in the repertoire of both science teachers and science communicators (Van Dijck, 2003).

Science fiction is often roundly criticized by scholars and educators as misleading (Michael & Carter, 2001), as a significant source of students' misconceptions (Barnett *et al,* 2006) and sometimes as offering a distorted and stereotypical view of science and scientists, especially in science fiction films (Haynes, 1994:50-56; Thacker, 2005:140-142; Weingart, 2003). However, as science fiction can have a substantial impact on students' scientific ideas (Barnett *et al,* 2006) as well as on their cultural response on science (Bates, 2005) it is important that teachers and science educators not only be aware of the ideas that are presented in science fiction but also be ready to confront this issue in science teaching in the classroom. (Jane *et al,* 2007). Therefore, rather than avoiding using science fiction in schools it may be a better strategy to engage students in the critique of science fiction (Barnett *et al,* 2006).

This Case Study refers to the research conducted with primary school students examining whether they can identify the 'scientific context' through analyzing science fiction stories involving extraterrestrial intelligence as well as the ethical, moral, political and cultural issues raised in the stories. In addition, we examine whether they can write science fiction stories of their own using scientific elements in order to make their stories plausible.

This study is a part of a wider research project whose main aim is to examine whether science fiction texts can be used as supplementary educational material in a cross-disciplinary approach between Science and Humanities in Primary School (Stavrou & Skordoulis, 2008; Stavrou *et al,* 2009).

In this Case Study we have chosen the “extraterrestrial intelligence” issue taking advantage of the intense interest that young students have in the existence of extraterrestrial life to introduce them with the multidisciplinary sciences, as this issue involves astronomy, life sciences, earth sciences, biology, chemistry, and physics problems associated with the question of the existence of life inside or outside our solar system (Brake *et al,* 2006; Griffiths *et al,* 2001; SETI, 2003). Moreover, students are given the opportunity, through the subject of “extraterrestrial intelligence” to confront controversial topics, such as ‘otherness’ and to deal with moral and ethical issues as well as perspectives about humanity’s situation in the universe (Griffiths, 2009; Saunders *et al,* 2004).

In the condition of the classroom the concepts of “difference” and “commonality” regarding “extraterrestrial intelligence’, could be a starting point in understanding how acts of meaning and interpretation, identity, and ending of subordination can share similar features. Recognizing the similarities in feelings, in counteractions, despite the sundry differences that students have with extraterrestrial beings, sets no determining direction or final outcome for social conflict. At best, the struggles and hopes supported by this point of view share a sense of community, dialogue, and intersubjectivity that bind peoples (SETI, 2003).

METHODOLOGY

Due to the fact that this study is part of a wider research project aiming at examining whether science fiction texts targeted at adult readers could be used in the context of educational process in primary school, we designed and conducted the following Case Study (Yin, 2003).

Case Study Protocol

Research Questions

- Whether students can identify the ‘scientific context’ and associate it with the literary context of a science fiction text.
- Whether students can identify the ethical, moral and political issues raised by the extraterrestrial intelligence issue.
- Whether students can integrate scientific elements into literary context in their own stories.

Sample

The research was conducted with a sixth-grade primary school class of 30 students (12 years old) of 16th Primary School of Athens, situated in the centre of the city. The majority of them came from low-income and middle- income families. Thirteen (13) of the students were children of financial immigrants, five (5) of which faced difficulties in understanding Greek language.

Our research consisted of five two-hour sessions which covered a period of five weeks.

Over this period and during their physics lessons, we worked out the scientific viewpoint of extraterrestrial intelligence using magazine articles and the Internet.

Procedure - Implementation

I) Initially students were asked to answer a *Questionnaire,* which consisted of 4 open questions and 2 closed questions, in order for us to examine the students' perceptions of extraterrestrial intelligence as well as the students' knowledge of scientific inquiry concerning the subject. The questionnaire, in the context of the present study, was given to students as an introduction to the subject of 'extraterrestrial intelligence, therefore, it is not part of the conclusion procedure.

II) *Reading and analyzing the texts*: Thereafter, the students were presented with the following science fiction texts (stories) involving extraterrestrial intelligence and they were asked to study and analyze them, in order to reinforce their ability to examine, to associate and to justify both the scientific and literary elements in the text.

Science Fiction Stories

- "Report on Planet 3" (1959) by Arthur Clark (short story): Being a report of Martian scientists on planet Earth, yet containing the 'scientific assumptions' of earthly scientific community. It also addresses the 'what if 'assumption of science fiction.
- "The Heavenly Host" (1975) by Isaac Asimov (short novel): Newly arrived on planet Anderson Two, just before Christmas, Jonathan, child from Earth, is warned about the dangerous native inhabitants, but an accidental meeting with one of the natives convinces him that they are friendly and peaceful. He devices ways to communicate with an 'alien child' based on shared feelings rather than conventional language.
- "Moby Quilt" (2001) Eleanor Arnason (short novel): The teaming of disparate species (squid-like aliens and humans) together to investigate the possible sentience of one another. At its core the story is essentially an exploration of different kinds of intelligence. In this story AI (Artificial Intelligence) has the role of benevolent mentor.

The above texts were chosen on the basis of the following criteria: a) they were written by acclaimed and awarded science fiction writers b) they refer to socio-scientific controversial issues c) the extraterrestrial beings are depicted in a positive way.

The textual analysis was based on the elements comprising the "scientific context" of the stories. The term "scientific context" refers to scientific concepts, scientific instruments as well as the authors' scientific assumptions. In these particular texts it is concerned with the planet's position in the universe (planet or satellite), the planet's conditions (the composition of the atmosphere, climate, its flora and fauna), the references to scientific instruments, the extraterrestrial beings themselves and the ways of communicating with them as well as the authors' scientific assumptions.

Having read and analyzed each text, the students had to work on a *worksheet* on the 'scientific context' of the text, as well as the characters, their actions, the facts and the plot. The worksheets were designed in order for us to examine the students' ability to identify the literary elements, such as theme, plot, setting and conflict and associate them with the scientific elements of the stories, such as scientific concepts, instruments as well as the authors' assumptions. In addition, through the *worksheets,* we examined the students' ability to highlight any societal and /or ethical, moral and political issues raised by the extraterrestrial intelligence subject.

III) In the next stage, the students were asked to write their own stories in order for them to elaborate further on the issues presented. Even if they didn't manage to write a complete

story, they were asked to come up with a plot outline and then discuss how “scientific context” would play a role in the story they envisioned.
The students’ writing assignments were examined in the light of their references to:
a. The way in which they used the “scientific context”.
b. The way in which they used literary elements such as plot, characters, setting and their assumptions of the theme of extraterrestrial intelligence and the way they associated them with ‘scientific context’.

Our data (worksheets and science fiction stories by the students) were analyzed in accordance to “Qualitative Content Analysis” (Mayring, 2000, Krippendorff, 2004).

I) Worksheets: For each worksheet we established the following *categories* and *subcategories*

Category: Identification and recording of ‘scientific context’ of science fiction text.
Subcategories
Complete identification and recording of ‘scientific context’: worksheets containing complete identification and recording of scientific elements of ‘scientific context’ (scientific concepts, scientific instruments as well as the authors’ scientific assumptions).
Adequate identification and recording of ‘scientific context’: worksheets lacking one of the aforementioned scientific elements.
Deficient identification and recording of ‘scientific context’: worksheets lacking more than one scientific elements.

Category: Connection of ‘scientific context ’with literary context.
Subcategories
Setting: worksheets in which the scientific elements are associated with the setting of the story.
Characters: worksheets in which the scientific elements are associated through the characters.
Plot (‘scientific’ assumptions’): worksheets in which the scientific elements are associated with ‘scientific assumptions’ contained in the story line.
Conflicts: worksheets, in which the scientific elements are associated with conflicts, either these concern the characters or the plot.

Category: Ethical, moral, political and cultural issues
Subcategories
With reference to scientific research: worksheets that contain references to ethical, moral, political aspects of the scientific research presented in the text.
With reference to scientists: worksheets that contain references to ethical, moral, political aspects of the scientific community and scientists characters presented in the text
With reference to Human – alien encounter: worksheets that contain references to ethical, moral, political aspects of encounters between humans and aliens as presented in the text.

II) Science fiction stories written by the students
In order to analyze the science fiction stories written by the students we established the following *categories:*

Categories

Category: ‘scientific context’: stories in which students use scientific elements in order to make their story plausible.
Category: ‘literary context’: the literary elements of each story as setting, characters, plot.

Category: Integration of 'scientific context' with literary context: stories in which the scientific elements are associated with literary elements in order for the students to put forward their claims and reasoning.
The questionnaire was also analyzed with "Qualitative Content Analysis" but as we mentioned above, was given to students as an introduction to the subject because our study was conducted in class conditions.

RESULTS

I) Questionnaire

The scientific research concerning extraterrestrial intelligence.
As far as scientific research was concerned, 27 students mentioned NASA's and SETI's Projects, the radio telescopes as well as the Hubble space telescope, while only 3 of them mentioned, manned or not spacecraft missions.

Concepts and standpoints concerning extraterrestrial intelligence.
All the students held a firm belief in the existence of extraterrestrial beings. 25 of them claimed that there was extraterrestrial life in the solar systems of our galaxy or in other galaxies apart from ours. 21 of them considered the beings to have humanlike characteristics, including the ability to express emotions, and 19 of them believed that such beings possessed higher intelligence than that of humans.

Ethical, moral, political and cultural issues concerning scientific research for extraterrestrial intelligence.
16 students maintained that the scientific research for extraterrestrial intelligence promoted the advance and development of science and technology, while 18 of them believed that such research was carried out for the purpose of humanity's future colonization of other planets. Only 2 students believed that the research aimed at finding out the extraterrestrial beings' intentions concerning the earth.

II) Worksheets

- "Report on Planet 3":

Category: Identification and recording of 'scientific context' of science fiction text.	
Subcategories	
Complete identification and recording of 'scientific context'	28
Adequate identification and recording of 'scientific context'	2
Deficient identification and recording of 'scientific context'	-
Category: Connection of 'scientific context 'with literary context.	
Subcategories	
Setting	30
Characters	30
Plot ('scientific' assumptions')	27
Conflicts	28
Category: Ethical, moral, political and cultural issues	
Subcategories	
With reference to scientific research	30
With reference to scientists	30
With reference to Human – alien encounter	30

All students mentioned and elaborated on the subject of the 'scientific context' of the text, as it refers to a Martian scientists' report on Planet Earth. Students could link the text's 'scientific context' with literary context when the former had reference to setting, characters and conflicts, whereas they were confronted with some difficulties to define the 'scientific assumptions' which were enunciated to the plot of the story.

- "The Heavenly Host":

Category: Identification and recording of 'scientific context' of science fiction text.	
Subcategories	
Complete identification and recording of 'scientific context'	29
Adequate identification and recording of 'scientific context'	1
Deficient identification and recording of 'scientific context'	-
Category: Connection of 'scientific context 'with literary context.	
Subcategories	
Setting	30
Characters	30
Plot ('scientific' assumptions')	30
Conflicts	30
Category: Ethical, moral, political and cultural issues	
Subcategories	
With reference to scientific research	30
With reference to scientists	30
With reference to Human – alien encounter	30

The majority of students (29 students) mentioned and elaborated on the subject of the 'scientific context' of the text (planet's position, existing life forms – means of communication with them) and all of them associated it with literary elements.

- "Moby Quilt":

Category: Identification and recording of 'scientific context' of science fiction text.	
Subcategories	
Complete appreciation and recording of 'scientific context'	25
Adequate appreciation and recording of 'scientific context'	1
Deficient appreciation and recording of 'scientific context'	4
Category: Connection of 'scientific context 'with literary context.	
Subcategories	
Setting	25
Characters	30
Plot ('scientific' assumptions')	23
Conflicts	28
Category: Ethical, moral, political and cultural issues	
Subcategories	
With reference to scientific research	23
With reference to scientists	28
With reference to Human – alien encounter	28

While analyzing this text, which was the most difficult of the three, some of the students (5 students) couldn't soundly identify the scientific elements (as Artificial Intelligence) and associate them with literary context. These were the students that found it difficult to complete the worksheets as well, and they were the ones that had difficulties in Greek language. Nevertheless, these students (5) did remarkably well in the first two stories.

In all three texts (stories) students were at ease associating the scientific elements with literary elements as well as raising the ethical, moral and political issues involved, especially concerning scientific inquiry as well as the scientists' role. It's worth mentioning that all students paid special attention to the colonization of other planets convention, which was mentioned in two of the texts, and according to which, humans do not have the right to colonize planets where there is intelligent life.

Science fiction stories written by the students

Categories

Category: 'scientific context'

As far as the students' writing assignments (stories) are concerned, the "scientific context" was focused on the conditions of the planet (24) and the description of the beings (21), without however any effort on their part to associate the beings' appearance with the conditions existing on the planet.

Category: 'literary context'

Fictionally, their stories, mostly (29 stories) involving two characters - the child itself and an alien creature - were set on almost all occasions on another planet but earth, except one set on earth. The 'aliens' were always depicted as friendly beings that meant no harm to the human race and, most of the times (28 stories), were in need of help. The student protagonist, who in all of the stories held the role of a scientist, always prevailed without any evident conflict.

Category: Integration of 'scientific context' with literary context

The majority of students (29) failed to fully integrate the 'scientific context' in the 'literary context', in their stories, in accordance to science fiction conventions.
Ultimately, the students were eager to write a story and they took special care to present a piece of writing devoid of spelling errors.

CONCLUSIONS

Although the students were not familiar with written science fiction, they were at ease identifying, writing down the 'scientific context' of science fiction texts and making associations between the scientific and literary elements of a story, especially when presented with texts referring to subjects familiar to them.

Throughout the process the students were successfully motivated to get involved both in physics sciences and in fiction. In particular, the texts' reading as well as the worksheets, succeeded in arising all students' interest. Even immigrant students kept asking questions about definitions of unknown words. All students eagerly participated and managed to comprehend and process the "scientific context" and the literary elements of the texts. They also very easily processed the societal, ethical and moral issues raised concerning scientific inquiry, scientific community and human-alien encounter.

Because of their engagement with science fiction texts students were queried and discussed not only about scientific issues but also about social and scientific ramifications on finding intelligent life on another planet as well as human's role in the cosmos. Consequently, selective science fiction texts can be useful and effective teaching tools in Science Education.

ABSTRACT

The research reported in this paper was conducted to determine if student teachers enrolled in a Bachelor of Education programme at a South African University, are able to integrate Science and Technology in their teaching. The participants were a cohort of students registered for a course aimed at preparing them to teach in the primary school. The theoretical framework which frames this study is based on Rogan's analogy that curriculum strategies are good when they proceed just ahead of current practice i.e. are within the Zone of Feasible Innovation (2006). Students' understanding of integration was compared to their knowledge base. The findings show that students who intend teaching in the Grades 4 to 6 in the B.Ed programme generally have a poor grounding in Learning Areas such as Science and Technology. Given the reluctance of students to engage with these two learning areas, expecting them to engage in the integration of the two, is too difficult for the vast majority of students in this module. The ZFI for these students implies better preparation in the basic learning areas with regard to content as well as teaching strategies.

Keywords: *teacher education*, *integration, science and technology, curriculum strategies*

INTRODUCTION

One of the many changes implemented with the advent of democracy in South Africa, was the introduction of a new education system. The introduction of Curriculum 2005 (C2005), (DoE 1995) as a single national curriculum for everyone heralded a different approach in education as C2005 advocated an interdisciplinary approach to education. While the advent of a new innovative education system was widely welcomed, the problem of implementing such a radically different curriculum soon became evident. Curriculum developers had high hopes for this curriculum, but the reality was that implementation of this curriculum was more difficult than anticipated.

BACKGROUND

The B.Ed programme at a South African University contains three modules referred to as 'Learning Area Studies'. These modules are aimed at teaching students how to integrate the different learning areas as prescribed by the national curriculum (C2005). One of these modules focuses on the integration of the Natural Science and Technology Learning Areas

(LAS 310). This module is compulsory for students who register for courses preparing them to teach from Grades 4 to 6 (the intermediate phase). As C2005 expects teachers to present learning programmes in the Intermediate Phase in which Science and Technology are integrated, the aim of this module is to teach students how to effect such integration. Integration in this context refers to the ability to design activities for learners in which they achieve Learning Outcome 1 of Natural Science (Scientific investigation), as well as Learning Outcome 1 of Technology (Solving a technological problem). While the intention is a noble one, the reality is that a large number of students who register for this module had very little exposure to Science and Technology during their school years. Added to this, many students do not register for Science or Technology modules in the B.Ed programme. Such students come into the LAS 310 course with no background in Science or Technology. Those registered for the Grades 7-9 programme must register for at least one of the Mathematics, Natural Science or Technology Learning Areas. This is in accordance with the regulations set out in the Norms and Standards for Teacher Education (DoE 2000).The result is that students who register for LAS 310 often have little or no grounding in Science or Technology. Very few select both Natural Science and Technology as their Learning Areas of choice.

THEORETICAL UNDERPINNING AND LITERATURE REVIEW

The conceptual framework underpinning the study is an adaptation of Rogan's Zone of Feasible Innovation (ZFI), (2006). While Rogan used the construct to frame curriculum levels within a schooling context, the construct will be applied to innovation in the B.Ed curriculum in a teacher education programme. The ZFI is analogous to Vygotsky's Zone of Proximal Development (ZPD) which is defined as the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers (Vygotsky 1978 ,86).

Rogan uses the analogy that curriculum strategies are good when they proceed just ahead of current practice i.e. are within the Zone of Feasible Innovation (2006). The ZFI in this context comprises content knowledge, as well as teaching and learning strategies within the context of C2005 that are realistic and achievable (Rogan 2007). This would include compulsory modules in the Natural Science and Technology Learning Areas that are achievable for students selecting the Intermediate Phase for teaching. 'The strategies in the ZFI are regarded as stepping stones to some defined goal, which is not yet attainable given the prevailing context' (Rogan 2006, 441). The defined goal in this context is a course aimed at developing the skill of designing integrated science and technology activities, and this research is aimed at determining what the steps within the ZFI should be to attain this goal. While the use of the term innovation may be questioned with regard to student learning, its use is deemed appropriate as the curriculum for teacher education was designed to meet the needs of C2005 which is deemed a curricular innovation.

Rogan (ibid) describes his ZFI as 'a collection of teaching strategies that go beyond current practice, but are feasible given the existing resources available to the teacher, or group of teachers and the prevailing environment of the school in terms of its availability to foster and sustain innovation. In our adaptation of Rogan's ZFI we pay less attention to resources, than to student teachers' knowledge of science and technology which operates as the ZFI. We wish to determine what the steps would be that are deemed 'beyond current practice' but progress to the defined goal. In the light of this conceptual framework, the research question we wish to address is if the reason for many students' inability to integrate science and technology effectively in the design of activities is due to the fact that the structure of this B.Ed Programme is not within the ZFI?

In this module students are not only required to interpret and implement Learning Outcomes 1 of the Natural Science and the Technology Learning Areas respectively (Appendix 1); they are expected to design activities in which the two outcomes are integrated. Many researchers report on curriculum policies that are ambitious in their goals of implementing change over short periods of time. Hargreaves (1998) points to the fact that when intended change is too broad and ambitious it often results in no change at all.

Joseph and Brooks (2008) report on a project where an integrated science and technology approach was introduced in certain elementary schools in the state of New York. To facilitate this approach, teachers were required to observe demonstration lessons by the researchers with classes and engage in discussions after the lessons, prior to them attempting to apply this integrated approach themselves. It would appear that, despite the fact that teachers may be experienced, if their knowledge base is weak, curriculum change is very difficult.

If integrating Science and Technology in education appears to be such a challenge, it raises the question why South African curriculum developers would introduce integration in the Intermediate Phase, given the many challenges which confront education? One reason may be the realisation that developing a scientifically and technologically literate citizenry requires not only the inclusion of the two disciplines in the curriculum; it necessitates the understanding of the link between the two disciplines. A developing country such as South Africa is in dire need of scientific and technology literate citizens as this can alleviate poverty, while developing useable skills required by developing countries (Blueford & Rosenbloom 2003).It is for this reason that UNESCO (in Blueford and Rosenbloom) supported the development of an innovative curriculum to support developing countries This integrated Science-Technology-Mathematics approach lends credence to the integrated approach suggested by C2005. This approach aims to develop critical thinking that can be applied to problem solving in real life situations. The purpose of an integrated Science and Technology Curriculum in the Intermediate Phase is to develop precisely these skills which are demonstrated with the achievement of the Natural Science and Technology Learning Outcomes 1 respectively. For teachers to facilitate the development of such skills, they should possess these skills themselves.

Technology is very much part of our lives- we live in a technological society where technological inventions permeate our lives. Yet Technology takes up little of our attention. Cheek (2000) bemoans the fact that although Technology is so pervasive, it barely is part of the consciousness of most Americans, despite the fact that they interact with technological systems and artifacts every moment of their waking lives. He ascribes this partly to the marginalisation of Technology in the curriculum. The planners of C2005 appear to have attempted to satisfy two opposing approaches. On the one hand, Science and Technology are presented as two separate learning areas; on the other, the curriculum suggests an integrated approach, albeit in the intermediate phase of schooling.

If Science and Technology are closely linked and should be viewed in an integrated manner, the question arises why the two disciplines have become separated to the degree it has been up till fairly recently. The separation of Science and Technology has developed over time and this separation has led to confusion as it creates the impression that the two are distinct disciplines and neglects the close relationship between the two (Zuga 1996) The two disciplines are enmeshed in their own culture and this separation has been extended into schools. Traditionally the two have been taught separately. The two disciplines operate differently –Science is abstract and theoretical and Technology is seen as practical. Zuga (1996), however, argues that the link between the two is too strong to present them so distinctly.

The Science-Technology-Society approach to Science Education is an attempt to develop scientific literacy by making students aware of the impact of Science and Technology on society. Both the technology and science curricula include a Learning Outcome (LO3) which is aimed at developing an 'understanding of the interrelationships between Science, Technology ,society and the environment (DoE 2002,18). By integrating Science and Technology it may be easier for learners to understand the impact of Science on society and lends further justification for curriculum developers to suggest integration. The STS movement advocates scientific and technological literacy as it is believed that literate people would be sensitive to issues that affect society. Rubba (1991) believes this is our only hope for resolving environmental problems. C2005 assumes that LO3 would achieve this, but this requires learners to think holistically. To achieve this would require the ability to integrate disciplines successfully.

Fears that integration would have a negative impact on Science as it would lead to the watering-down of Science is probably the reason why integration is only suggested in the Intermediate Phase and only implied in the higher grades through Learning Outcome 3. Integration implies a fundamental change in the way Science is presented as advocated by Fensham (in Aikenhead,2003) from learning science, to learning through science and a more 'science for society' approach.

In summary, the literature strongly supports the integration of Science and Technology and provides justification for the decision taken by the designers of C2005. The purpose of this research is to determine if students are in fact capable of integrating Science and Technology effectively, given their grounding in these disciplines.

METHOD

The research is framed by an interpretive paradigm as we wanted to find out what students' understandings and interpretations are of an integrated science and technology approach. Information from biographical data was used to determine what the students' background knowledge of Science and Technology was when they enrolled for LAS 310. Qualitative data obtained from a questionnaire and interviews provided deeper understanding of students' ability to design integrated science/technology activities. By determining what students understand and how they design activities, we were able to evaluate whether the outcomes as set out in the module are realistic and reachable i.e. whether they are located within the ZFI.

Table 1 Methods of Data Collection

Instrument	Purpose
1. Information sheet	To obtain information with regard to their previous experience of Science and/or Technology
2. Questionnaire	To probe their understanding of what the course entails
3.Examination task Students were expected to design an integrated Science/Technology activity.	While the examination results were not used as data in this study, the tasks were used as a basis for the interview
4.Interviews 12 students were interviewed	Interviews focused on the following aspects Students' understanding of the design process as set out in LO1 of the Technology LA Students' understanding of the scientific process and the process skills associated with the process Did the examination task demonstrate the integration of the scientific and technological process? Students' understand of Learning Outcome 3 of both learning areas and how to incorporate this Learning Outcome in their teaching.

The examination task

The task required students to demonstrate an understanding of what a scientific investigation entails as opposed to solving a technological problem. This means a student could use the technological process to design something (eg a rain gauge) that could then be used to carry out a scientific investigation (eg measuring rainfall over a period of time). Alternatively a student could use a scientific investigation to make decisions as to what kind of structure should be designed (eg subjecting certain materials to a test for durability, making a decision based on the outcome and using a particular material to build a structure).

FINDINGS AND DISCUSSION

Students' background in Science and Technology

The first set of data gave us some indication of the background students who enrolled for the course had in Science and Technology. Table 2 shows the results.

Table 2. Students' background in Science and Technology

A	B	C	D	E	F
General science (Grade 9)	Physical Science or Biology (Grade 12)	Natural Science LA (B.Ed)	Technology LA (B.Ed)	Science and Technology LA (B.Ed)	No LA (B.Ed)
		24=Int/Snr 1=Found/Int	11= Int/Snr 1= Found/Int	All(3) Int/Snr	All (24)Found/ Int
40,6%	57,8%	39,2%	18,7%	4,6%	37,5%

The table shows that only 57,8% of these students who will be expected to teach an integrated Science/Technology course to grade 4-6 learners were involved in science learning up to grade 12 during their school years, while 40,6% only had science up to grade 9.

With regard to students selecting Science and/or Technology, there is a clear pattern, as most students who selected these learning areas were Intermediate /Senior Phase students (Columns C, D and E). The Intermediate/Senior Phase students' who did not select mathematics, were obliged to select Science or Technology in the B.Ed programme. Natural Science or Technology was not compulsory for those students who were registered for the

Foundation/ Intermediate phase (Columns C and D) and the table shows that only 2 of them did.

Key questions exploring students understanding of the course
Students were asked three questions. Table 3 shows their responses.

Table 3. Students' expectations of the course

Questions	**Responses**	
What do you expect to gain from this module?	How to integrate Science and Technology	13,3%
	More knowledge of both learning areas	30,6%
	More Science knowledge	13,3%
	More Technology knowledge	5,3%
	Improved teaching of both learning areas	25,5%
	How to teach science	5,3%
	Other	6,7%
Do you foresee any specific challenges?	Too little background in Science and Technology	7,8%
	Too little science knowledge	13%
	Too little technology knowledge	6,5%
	Concern about projects in Technology	13%
	Responses not directly related eg, concerns about time, examinations, group work, class size etc.	22%
	No Challenges	37,7%
Do you think science and technology can be integrated?	Yes	87,8%
	Not sure	5,4%
	No	6.8%

With regard to what students expect from the course, it is significant that only 13,3% of the students expected to learn how to integrate science and technology knowledge in their lessons. The majority of students expected to improve their science and/or technology knowledge (49,2%). They are fully aware of the gaps in their knowledge and understand the importance of improving their content knowledge. A significant percentage also expected the course to enable them to teach the Natural Science and Technology Learning Areas. This response may be interpreted as including the ability to integrate the disciplines of Science and Technology in lessons, but the fact that some students mention both learning areas and others specifically mention science, seems to indicate that the teaching strategies referred to do not include integration.

With regard to possible challenges, a significant number foresaw no challenges(37,7%) this is possibly due to the fact that their expectations of the course were merely to improve their content knowledge and therefore was not seen as a problem. Their concerns lay with their weak knowledge base in Science and /or Technology, as well as the technology design they were expected to produce. The fact that no students were concerned about integrating Science and Technology demonstrates how far this construct is removed from their experience.

When the question of integration was pertinently put to them, the majority agreed that it was possible. This is an expected response as the fact that integration is a possibility was brought to their attention. More significantly however, is the fact that a certain number of students (12,2%) was either adamant that, or unsure if integration of these disciplines was at all possible. This may of course point to the possibility that they had a limited understanding at that stage of what integration entailed.

Interviews

Students generally find it easier to understand the technology process. Those who selected Technology as a learning area were able to design a task using the technology process.

> R: Would you say Technology is easier, because you did it in your degree or is it generally easier than Science or is Science more challenging?
> S1: I enjoyed Technology because for me it was easier

They find the scientific process much more difficult. Even the students who selected Natural Science, had difficulty in understanding what the process entailed.

> S2: Science was a big challenge for me. To integrate was very difficult. To integrate something that I did not know with something I knew, was a big challenge.

They did not understand what was meant by a hypothesis and could not describe the scientific process.

R: Let's look at your exam task- Natural Science LO1-what was the problem statement you identified?
S3: Pause
R: Do you understand the question?
S3: Not really.
R: OK –if you expected the learners to conduct the investigation. What was this problem?
S3: I have no idea
R: But an investigation is more than this is it not? It's about asking a question, formulating a hypothesis …….
S3: We missed that completely I think
S4: Well where we were at fault- we thought that by just planning the investigation –you know the steps –we thought that was more Natural Science, but actually it wasn't-but I think we did not really grasp that concept related to gravity
R: yes, because you took something that was actually a technology exercise

The biggest problem appeared to be the fact that students had difficulty distinguishing between the technology design and the scientific process. For instance, a student who designed a birdfeeder saw the design of the bird feeder as satisfying both the Technology and Natural Science Assessment Standards. She could not conceptualise how to use this technology design to do a scientific investigation

Students who had difficulty distinguishing between the technological and scientific processes invariably had difficulty integrating the two learning areas as the scientific process was left out in their planning. The most significant difficulty was differentiating between the meaning of what is meant by a problem in the two disciplines. They tended to see a scientific 'problem' as a barrier, rather than a leading or investigative question and tended to interpret a problem in the way it was used in technology.

R: Lets go on to the second section –integration. With regards to your exam task- looking at LO 1 of the Natural Science LA. Obviously you have to identify a problem- what was the problem the learners would identify?
S7: OK – they needed to identify the measurement of rainfall- how can they in the classroom develop something to measure rainfall.
R: Was this a scientific problem or a technological problem?

> S7: Well it's a bit of both –you need your science knowledge- you need to know about rainfall. And the tech knowledge, you can't just measure rainfall –you need to make something.

It would appear that the Technology Learning Area as offered in the B.Ed programme is sufficient to give students the necessary grounding to design technology tasks. However, the Natural Science does not appear to be sufficient as students expressed their lack of confidence to plan investigations and this was supported in the interview where it was clear that they did not understand what was meant by a scientific investigation. This lack of understanding hampers their ability to integrate the two learning areas. Even students who elected to do both science and technology as learning areas, expressed their lack of confidence in planning scientific investigations.

None of the Foundation/ Intermediate Phase students interviewed had Technology in their course, while two had Natural Science. These students had particular difficulty integrating Science and Technology as they had limited knowledge of the Technology as well as the Natural science learning outcomes. They did not fully understand the technological process and had a very poor understanding of what a scientific investigation entailed.

> S8: So it was difficult because it is kind of new to me. Even though I did the whole module, it was difficult for me. The integration was difficult to grasp and everyone had a problem there.

The interviews revealed serious shortcomings in students understanding of the technological and scientific processes respectively and these shortcomings made it difficult for them to design integrated activities.

CONCLUSION

The findings show that students who intend teaching in the Grades 4 to 9 generally have a poor grounding in Learning Areas such as Science and Technology. In the B.Ed programme described in this study, students prefer to select learning areas other than Science or Technology. It is only when they have no choice that they select one or the other; seldom both. Out of a cohort of 64 students only 3 selected both learning areas.

Given the reluctance of students to engage with these two learning areas, expecting them to engage in the integration of the two, is too difficult for the vast majority of students in this module. The ZFI for these students implies better preparation in the basic learning areas with regard to content as well as teaching strategies. Expecting them to integrate the learning areas is unrealistic and not feasible. While the designers of the B.Ed curriculum at this institution attempted to align the curriculum with C2005, this has resulted in the inclusion of a module that is impractical as most students benefit very little from it. The argument is that poor performance of students is due to the fact that they are expected to demonstrate the ability to transfer concepts between Science and Technology, as well as the integration of science and technology processes in lesson planning, while they lack the basic knowledge in Science and Technology. This is not realistic or achievable The boundry of a ZFI in this context needs to be redefined to include only Technology and Science, rather than a module that requires students to integrate Science and Technology in lessons. There is no opportunity for these students to scaffold their knowledge as they do not have the basic science and technology knowledge on which to build. Students who lack sufficient knowledge of Science or Technology may find it very difficult to interpret the learning outcomes of either learning area in such a way that would enable them to integrate the two effectively.

Appendix 1

Learning Area Studies 310: Examination - June

1. Examination dates: 25, 26, 27 May

- Indicate on the list on which day you prefer to do your presentation.
- It is compulsory to be present for all presentations **on the day** you present as you will be requested to assess your peers as they present

2. A maximum of two people per presentation.

- You will be allocated 15 minutes for your presentation.
- Both you and your partner must participate in the presentation.

3. TASK

- Select a topic from the Natural Science Intermediate Phase Curriculum or the Technology Intermediate Curriculum. Choose a topic that you **HAVE NOT** covered in class.
- Indicate the Grade that your activity is aimed at.
- The RNCS for Natural Science discusses Learning Outcome 1 on page 8 where it refers to four kinds of practical problems that learners may investigate. One category is problems of making.
- Select an activity that allows learners to put their mind to a 'problem of making' that will require them to construct something. This also encompasses Learning Outcome 1 of Technology: "The learner will be able to apply technological processes and skills ethically and responsibly using appropriate information and communication technology" (DoE, 2002, p.31)
- Your activity must engage learners in a scientific investigation which involves Learning Outcome 1 of Natural Science: "The learner will be able to act confidently on curiosity about Natural phenomena, and to investigate relationships and solve problems in scientific, technological and environmental contexts." (DoE, 2002, p.16)
- Build an example of a construction you would expect learners to make.
- Prepare a poster indicating what the chosen activity is. Your poster should clearly display the Learning Outcomes and Assessment Standards that your activity addresses.
- Give an explanation of how the Technology Learning Area Learning Outcomes and Assessment Standards may be attained when learners make the construction.
- Give an explanation of which Natural Science Learning Outcomes may be achieved through this activity and how they are achieved.
- Explain exactly how the selected Assessment Standards may be attained.

STUDENT-TEACHERS EXPLAINING ACIDIFICATION IN THREE DIFFERENT SCALES: A CASE STUDY

ABSTRACT

In the context of Environmental Science in Education students study phenomena and problems occurring on a time and space scale which is too large to be immediately perceived. Such occurrences are interpreted through processes and changes taking place in macro scale, while the macro scale processes themselves are interpreted by means of models of systems and processes at cellular and atomic molecular scales – micro scale. In order for us to analyze the way student-teachers link the three levels of understanding (micro, macro and large scale) so that they will be able to explain the environmental phenomena and problems, we designed a didactic intervention addressing the issue of acid rain interaction with the natural environment on all the three scales. The students' pre-tests post-tests and worksheets analysis showed that, although the students were not eager to use models of the micro scale in their explanations, the contact with the models and processes on micro scale through educational software rendered the majority of them able to correlate the macro with large-scale changes in their explanations.

Keywords: *Environmental Science, student-teachers, acid rain*

INTRODUCTION

Recently, the need for introducing the environmental dimension of science in education has become prominent (Gough, 2002; Edelson, 2007). Usually, in the context of Environmental Science in Education students study the natural dimension of environmental systems, which are complex socio-ecological systems. This study concerns phenomena and problems such as the hole in the ozone layer, acid rain and the greenhouse enhancement effect, that take place on a very large scale of time and space (Mitchell, 1989; Tett *et al,* 2000; WMO, 2007; Akselsson *et al,* 2003), and, therefore, can not be fully perceived. These phenomena can only be conceived and interpreted via macro-scale changes and processes that can be perceived directly (ranging approximately from 1mm to 1km). Macroscopic systems and processes are explained "using models of systems and processes that are too small to see, at the cellular and atomic-molecular scale", micro scale (Anderson, 2007).

The objective of this study is to examine the way student-teachers link the three levels of understanding of the natural world (micro, macro, large) when interpreting environmental phenomena and problems. In particular, this is a case study examining student-teachers ability to perceive and explain the interaction of acid rain with the natural environment. The fundamental factor of this interaction is the acid / weathered bedrock reaction when acid rain penetrates the soil. When soil buffering capacity is strong (calcareous subsoil) the weathered rock (soil minerals and weathered bedrock) reacts with acidic water beneath the soil and neutralizes the acidity, thus protecting aquatic and terrestrial ecosystems. When soil lacks buffering capacity (siliceous subsoil) ecosystems are, in the long run, strongly affected (JCE, 2003). The occurring reaction is perceived at macro level but is explained at a molecular level (micro scale) and its results can be seen in ecosystems in a time range of some decades (large scale).

METHODOLOGY

The research questions of this article are:
1. In which way students describe and explain the reaction that underlies the different effect of acid rain on different ecosystems?
2. Which scales are used by the students when they describe and explain the acid rain effect on the natural environment?
3. In which way the students' contact with models and processes of micro scale influences their ability to explain the phenomenon in macro and large scale?

The research described here was conducted in a class of 59 pre-service teachers, students of the National and Kapodistrian University of Athens who attended the one-semester course "Natural and Environmental Sciences – a Laboratory approach" in 2008-2009. In the above mentioned course, students study modern environmental problems, acid rain being one of them. Acid rain is included in the course curriculum since Athens city has been faced with a serious acid pollution problem resulting in the permanent degradation of some of the most important monuments of its cultural legacy.

Nowadays, as a result of intense effort and environmental measures taken, a reduction of the acid pollution in Athens has been achieved, although acid pollutants have not been entirely eliminated (Adamopoulos *et al,* 2009). Although the main concern of our study is the acid rain / natural environment interaction, acid rain / human environment interaction is important for the course curriculum. Therefore, we constructed a didactical intervention in which, without underestimating the part of study concerning the acid rain effects on monuments, the study of acid rain / natural environment interaction is appropriately integrated and emphasized in the didactical activities.

The didactical intervention:

Before the actual didactical intervention a pre-test was filled in by the students. This pre-test contained both multiple-choice questions in which justification was asked for their choices, as well as open-ended questions. This pre-test was the first source from which we drew upon our first data collection for our research. More specifically, the students' answers in 7 key questions of this questionnaire comprised the 1st data collection.

Initially, students approached the acid rain / environment interaction in macro scale in the wet lab where they tried the way in which acids interact with siliceous and calcareous materials in order to elaborate on and answer the following questions: 1)How does the kind of the stone used as building material affect the vulnerability of constructions in case of acid pollution attack? 2) Is it possible that the underlying bedrock of an ecosystem can affect its interaction with acid rain and in what way? Students were given worksheets in which they concisely recorded the experiments they designed and executed, and answered the two questions according to their findings. The answers in the second question comprised our second data collection.

Afterwards, in the computer laboratory students, in groups of two, investigated the way acid pollution affects different semi-natural environments (large-scale approach) with the use of educational software. Approximately half of the groups built a virtual semi-natural landscape with underlying siliceous bedrock. The landscape consisted of a forest of various trees near a lake and an industry on the other side of the lake. Near the lake they also built a statue made of indigenous material (granite). The remaining groups built a similar virtual landscape but with calcareous bedrock and erected a statue from marble which was abundant in their local landscape. All groups filled in worksheets in which they recorded the changes that they observed occurring in the landscape under the influence of acid pollution. That means, changes to the statues' condition, changes in the life of ecosystems and the physicochemical properties of the abiotic factors of ecosystems such as soil pH, pH of rain clouds and fog, as well as the lake water pH. In addition, students were able to record some other physicochemical properties of abiotic factors such as detection of air pollutants, the presence of nutrients or poisons in the soil -depending on which of those properties they considered important for the study of the evolution of the landscape.

When the groups finished the exploration of the virtual landscapes, all of them discussed their findings together. They compared the different evolutions of their virtual landscapes, and they talked about their observations. Finally, they recorded their opinion on how acid rain affects the environment. These recordings are the third collection of data (texts) to be analyzed in order for us to answer our research questions.

The third stage of our didactical intervention took place in the computer laboratory again using the same educational software. Students, again teamed up in groups of two, investigated the nature of acid rain, and the importance of acid / rock reaction at the microscopic scale. More precisely, they built virtual landscapes (similar to the above mentioned) where they "zoomed in to the micro scale dimension" of the rain falling in order to "see" the acids dissociation and have a clearer idea of the concept of acidity and, consequently, of the meaning of acid rain. In order to "see" the deeper explanation that chemistry can offer on acid / rock interaction, all of them built virtual landscapes resting on calcareous bedrocks, with marble statues. Students zoomed in the microscopic scale of this reaction taking place on the statue material, an interaction that at macroscopic level is interpreted as monument erosion. They also studied the same reaction as it occurred in weathered bedrock (stones and minerals) as the acidic waters flowed in the soil, leading to neutralization and therefore, to ecosystems protection. In the last part, of this stage of the didactic approach, all groups discussed the way acid rain affected the city of Athens, which is founded on calcareous bedrocks, and wrote down their own conclusions. These last recordings comprised our 4rth data collection. After the didactic intervention, students completed post-tests. The post-tests were not identical to the pre-tests, but all questions corresponded to the pre-test questions. The students' answers in 7 key questions of the post-test, corresponding to the 7 key questions of the pre-test, comprised the 5th data collection. These pre and post-test key questions, gave students the opportunity to describe in detail how they perceived the acid rain / environment interaction. Four of these questions (1st set of questions) encouraged students to describe this interaction without introducing the "type of underlying rock" factor. The other three (2nd set of questions) encouraged students to describe this interaction by introducing this factor, thus providing students with the opportunity to express their opinion whether and how the rock may affect the impact of acid rain on ecosystems.

As far as these two sets of questions are concerned, a first analysis showed that in the pre-test students answered the two sets of questions in a different way. So, when analyzing pre-tests, we analyzed the two sets of answers separately. However, in the post-tests students answered all 7 questions in a way that their answers were complementary to each other, thus avoiding repetitions. The answers to the post-test 7 key questions were analyzed as a whole.

The fact that there were more than one questions concerning the same subject in the tests gave us the chance to compare the students' answers -in the varied questions- so that we would be able to interpret as accurately as possible the students' recordings. Thus, we accomplished internal validity which, obviously, is not identified with the strict objective validity of quantitative research (Winter, 2000; Velentzas, 2010, p. 183).

Similarly, in the worksheets the key questions were themselves part of a wider recording context in case the respective answers seemed controversial or difficult to be classified. In such case they could be clarified by means of students' recordings in relevant parts of the worksheet. Moreover, the fact that both the tests and the worksheets were filled in the context of the didactical intervention in real class conditions increased the data validity since the students were motivated to give veracious and clear answers.

Defining categories and subcategories for data quantification

In order to analyze our data (students' answers), we referred to previous researches of science didactics examining the way students describe and explain phenomena at different scales. In particular, we focused on the researches in which the phenomena explanation is based on chemical or biochemical reactions since this is the central theme of our case study (Mohan *et al;* Anderson, 2007; Ahtee & Varjola, 1998; Barker, 1999; Hesse & Anderson, 1992; Ardac & Akaygun, 2005; Solsona *et al,* 2003). Finally, we decided to perch on the study of Solsona *et al* (2003) in which senior high school students were categorized according to the way they described the concept of chemical change, a concept that was interpreted at two scales (micro and macro) in school science. This decision was taken because in that research the data were in form of texts, and our data are mainly texts too. A second reason for this decision was the fact that the way students interrelate processes and changes described at the macroscopic scale to the processes described at the microscopic scale, plays a key role in the data analysis in this research. This is something of great importance in our research too. The initial (Solsona's and her colleagues') categories were modified and expanded so that our data could be displayed more precisely, and the large scale which is absent from traditional Chemistry curriculum but is crucial in Environmental Science in Education could be included. Below we describe the categories and subcategories as they solidified and finally turned out to be a tool with which we were able to quantify our data.

1st category: "Levels". In this research, we considered as highest performance on the part of the students, their ability to describe the acid rain / natural environment interaction as following: At large-scale level we expected them to describe the different effects of acid rain on terrestrial and aquatic ecosystems depending on how the subsoil allowed or prevented the soil and water acidification. At the macroscopic-scale level we expected them to interpret the different effects of acid rain on surface waters and soils through acid / rock chemical interaction.

Finally, we expected them to use models of the microcosm to explain this interaction (microscopic-scale level). For this category the following subcategories were distinguished:

- "Non reference to interaction". When students don't describe processes or changes at all. This is depicted as "LØ" in tables and charts.
- "Large-scale level description". When students describe how acid rain affects abiotic factors and life in ecosystems. There may be different versions of their descriptions regarding how detailed the latter may be, which properties of abiotic factors the students focus on, and whether they describe both abiotic factors and their impact on life or only one of the two. This subcategory is depicted as "La" in tables and charts.

- “Macro-scale level description”. When students in order to describe how the acid rain affects the natural environment, they only describe the acidic water / stone interaction. This subcategory is depicted as “Ma” in tables and charts.
- “Description at Macro and Large scale levels which are not successfully interrelated”. It is a combination of the two above mentioned levels, macro and large, but without establishing the correct interrelation between the macroscopic and large levels. That means that macro-scale processes are described in such a way that they are inadequate to explain and justify what is described in large scale. This subcategory is depicted as “Ma#La” in tables and charts.
- “Description at Macro and Large scale levels which are successfully interrelated”._It is the correct combination between the macroscopic and large levels. This means that in their recordings, students describe the outcome they anticipate (or observe) of acid rain affecting ecosystems, and they explain their opinion based on the different way acidic water interacts with different kinds of rocks. This subcategory is depicted as “Rel(Ma,La)” in tables and charts
- “Description at Micro, Macro and Large scale levels which are successfully interrelated”. It is the perfect and thorough way of describing the environmental phenomena and problems. This means that recordings classified in this subcategory, not only explain the different ways acid rain interacts with seemingly similar ecosystems through acid /rock interaction, but also explain this interaction using entities and systems of the microcosm. In order for a text to be classified in this category, it is not sufficient to contain references to some entities of the microcosm, but should be obvious in the texts why these entities are important. This means that the microcosmic entities and processes mentioned must substantially contribute to the explanation of the observed changes at the macro and large scales. This subcategory is depicted as Rel(Mi,Ma,La) in tables and charts

2nd category: “kind of change”. Through this category we are trying to investigate how students understand the acidic water interaction with the natural environment in the two lower levels, namely microscopic and macroscopic level. As mentioned above, this interaction is defined by the acidic water / rock reaction in the soil, ie when this reaction is strong it buffers the acidity of abiotic factors (soil and water). Consequently, we are investigating how students understand and describe this very chemical reaction. In this category we distinguish the following subcategories.

- “No change statements given”._This subcategory is depicted as “ChØ” in tables and charts
- “Erosion”. When students refer to stone erosion, or stone plasterization by the acidic water percolating the soil, without giving more information about changes in properties or substances. This subcategory is depicted as “Ers” in tables and charts
- “Physical Change / Change in Properties”. When students describe the change of properties (acidity, calcium and aluminum concentration) resulting from the acidic water / stone (in the soil) interaction. Some of the texts belonging to this subcategory describe the interaction as mixing, absorption, dissolution, while others regard it as reaction. However, even in the latter texts, it is not clear that the students have fully understood the nature of the reaction. This subcategory is depicted as “Ph/Pr” in tables and charts.
- “Substance change”. When students, having fully understood the reaction, describe precisely the acid/stone interaction as formation of new substances from the initial substances which have practically disappeared. As the new substances’ properties are different from the initial ones, the reaction results in the change of properties in the reacting system. This subcategory is depicted as “Sub” in tables and charts.

3rd category: "Effects on Ecosystems". Through this category, we are trying to investigate how students understand the acidic water interaction with the natural environment at the large level, ie at the level where the evolution of entire ecosystems is observed. These changes are exactly the subject of environmental science, and it is because we need to predict and explain them that we study the changes at the lower two levels (scales). In this category we distinguish the following subcategories.

- "No effect statements given / undefined"_When students select "don't know" in multiple-choice questions, do not answer at all, or give an answer not relevant to the question. This subcategory is depicted as "NA" in tables and charts.
- "All Vulnerable"._When students describe damage that occurs in terrestrial and aquatic ecosystems but without considering the possibility of any factor in the ecosystems playing an important role in protecting the ecosystems from acid pollution.
- "Calcareous Vulnerable"_When students express the view that ecosystems with underlying calcareous subsoil are more vulnerable to acid rain attack than similar ecosystems with underlying siliceous subsoil.
- "Differentiated effects" When students consider that the different interaction of acid rain with the different rock types may be important to the ecosystems, but they also consider that the strong interaction with the calcareous rock results in both positive and negative consequences to ecosystems founded on such subsoils.
- "Calcareous Resistant" When students express the view that ecosystems lying on calcareous subsoil are more durable to acid rain attack than similar ecosystems lying on siliceous subsoil. This last view is the "correct approach" to the acid rain / natural environment interaction phenomenon.

RESULTS

Analyzing our data by means of the set of categories and subcategories described above, we derived the quantified results that are depicted on the tables that follow.

Table 1: quantification of 1st data collection, 1st set of questions

Effects on Ecosystems	Levels	kind of change	instances

Calcareous Resistant	LØ	ChØ	2
	Rel(Ma,La)	Ph/Pr	1

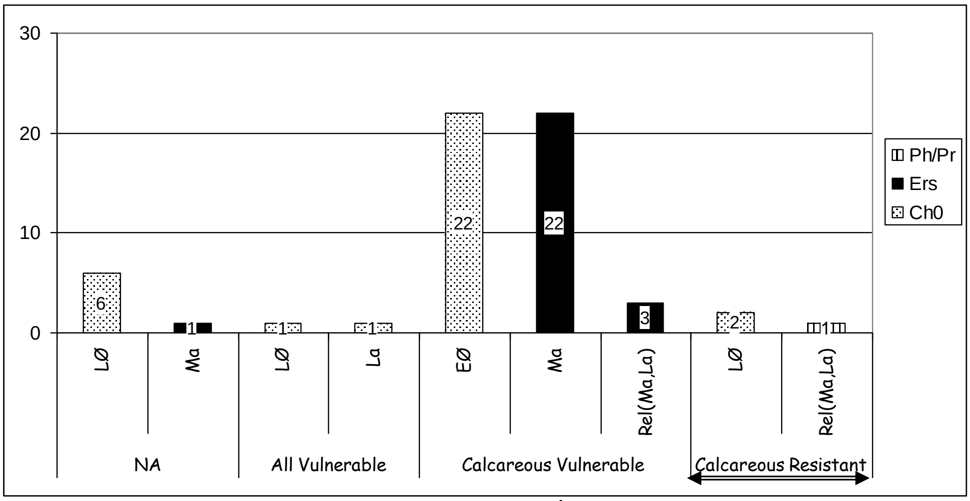

Chart 2: 1st data collection, 2nd set of questions

In the pre-tests students preferred to give large and macro-scale descriptions but without linking large scale changes described in the first set of questions to macro scale processes described in the second set of questions. So, in the first set of questions, the large majority (51 subjects) described the consequences that –in their view- acid rain had on ecosystems' abiotic factors (surface water acidification, soil erosion), but mainly on ecosystems' biota (trees and aquatic organisms). However, they didn't refer to the acidic water / rock interaction and, therefore, didn't distinguish between ecosystems more resistant or vulnerable to acid attack. In contrast, in the second set of questions, the majority of them (47 out of 59) thought that ecosystems resting on calcareous foundation were more vulnerable to acid rain attack. Approximately half of them justified their view by referring to their knowledge about acid rain / calcareous stones strong interaction. Therefore, they deduced that the rock vulnerability was somehow transferred to the ecosystem but without describing which factors of the ecosystem were influenced and in what way. Only 3 out of 47 referred to specific effects on abiotic factors (soil erosion, collapse of the terrestrial ecosystem). The other 22 did not justify their view at all.

Table 3: quantification of 2st data collection

Effects on Ecosystems	Levels	kind of change	instances

	Rel(Ma,La)	Ers	1
		Ph/Pr	4

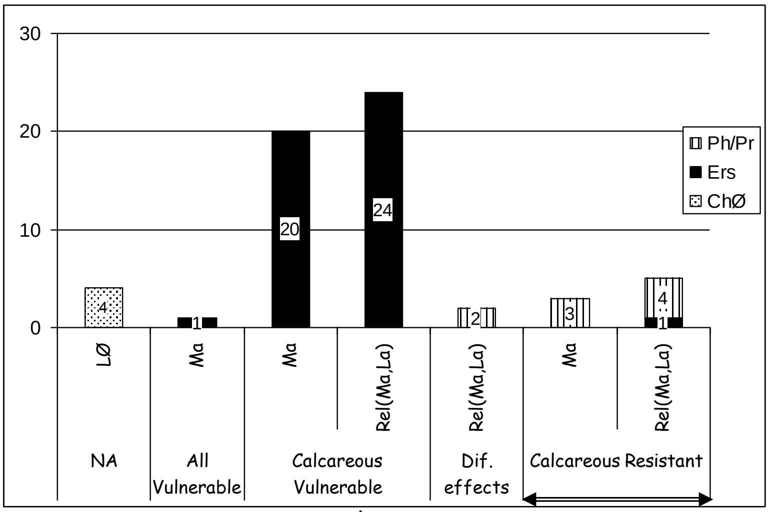

Chart 3: 2nd data collection

In the wet lab they tried different rock types interaction with acidic solutions and they confirmed their initial notion about the acid / calcareous stone strong reaction. From the experiment descriptions in their worksheets it can be derived that, although the vast majority of them measured the pH increase this interaction entailed, they persisted focusing on the destructive side of the reaction. Consequently, they deduced that this interaction led to natural environment erosion (which is wrong). Half of them suggested soil collapse, thus interrelating macro and large scales. However, a small part of the sample (9 subjects) begun to suspect the impact the pH change might have on ecosystems.

Table 4: quantification of 3rd data collection

Calcareous Resistant	La	ChØ	30
	Ma # La	Ers	3
	Rel(Ma,La)	Ph/Pr	19

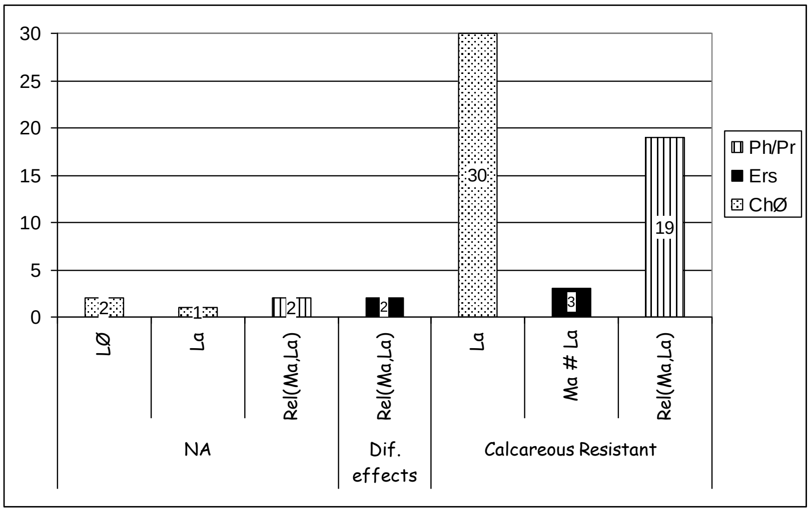

Chart 4: 3nd data collection

When, through the software, students approached the problem at the large-scale domain (ecosystems' long term alteration), the large majority described it at this scale correctly. Moreover, a remarkable part of the sample (19 subjects) were able to interpret the large-scale phenomena (different acid rain effects on, at first sight, similar ecosystems) by macro-scale processes, more specifically by the acid /stone interaction as acidic water percolated the soil. They described this interaction as a change in properties - mainly in acidity.

Table 5: quantification of 4th data collection

Effects on Ecosystems	Levels	kind of change	instances
Calcareous Vulnerable	La	ChØ	1
	Rel(Ma,La)	Ers	2
Differentiating effects	La	ChØ	2
	Rel(Ma,La)	Ers	2

		Sub	13
	Rel(Mi,Ma,La)	Sub	8

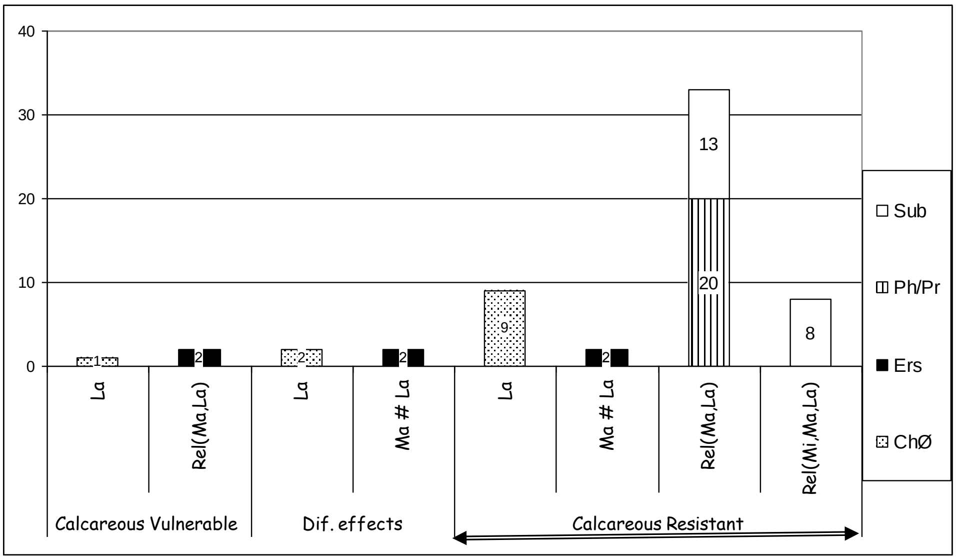

Chart 5: 4th data collection

When students, through the software, encountered micro scale systems and models they seemed to satisfactorily comprehend the chemical reaction and its significance to the ecosystem. Approximately one third of the sample described the reaction accurately as being a process of disappearance of some substances (the strong acid being among them) and a formation of new ones with different properties. One third of the sample described the reaction as a change in properties (mainly in acidity) without clearly defining this reaction. These two parts of our sample successfully explained what occurred at large scale through macro scale processes. However, only a small part of the sample (approximately 1/10), correlated the three scales (micro macro and large).

Finally, students described acid rain / natural environment interaction in a similar way in the post-tests as depicted in the following table and chart.

Table 6: quantification of 5th data collection

		Sub	9
	Rel(Mi,Ma,La)	Sub	6

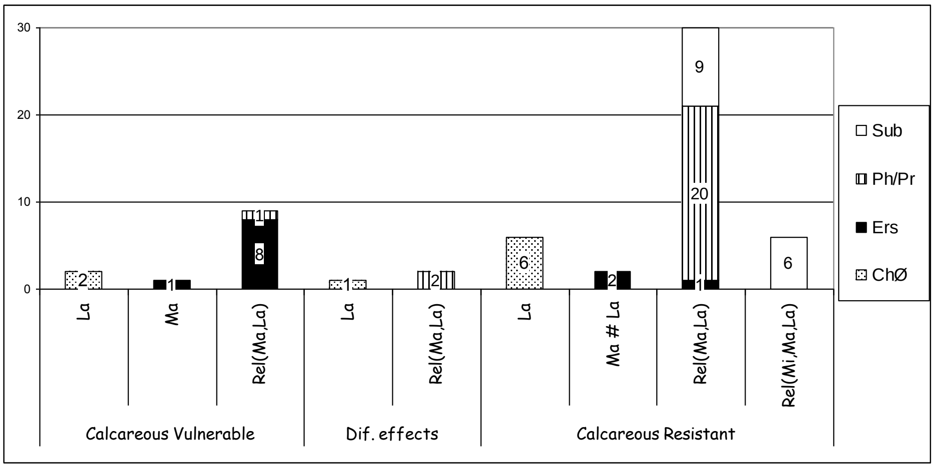

Chart 6: 5th data collection

CONCLUSIONS

In order to answer the research questions of the current study we had to observe and interpret the charts given in the results section. As far as the scales used by the students when they described and explained the acid rain effect on the natural environment are concerned, we noted the following: In the two first stages of the didactic intervention, students tended to describe the changes occurring in ecosystems (large scale), or macro-scale processes depending on the level on which the particular stage focused. A relatively small part of the sample tried to predict or explain the large-scale changes using deductions from the macro-scale ones. However, this did not occur in the third stage of the didactic approach which focused on micro-scale. That means that they did not incorporate microcosmic systems, entities and processes in their descriptions although microcosm was at play in this stage. However, it is worth mentioning that a larger part of them correctly interrelated changes and processes at the two higher levels, i.e. they correctly explained the way local bedrock offered (or did not offer) adequate protection to ecosystems from acid rain attack.

As far as the way in which students described and explained the acid / stone reaction is concerned, we noted that, initially, students (in the pre-tests and the first worksheets) described this reaction rather superficially, as damage to the stones. When the students interacted with the virtual landscape for the first time, they tried to explain their observations which, judging from their descriptions in the pre-test and the first worksheets, contradicted their initial views. Therefore, they began to describe the acid / rock interaction more precisely, by focusing on the properties changes this interaction resulted in. Finally, students' interaction with the virtual representation of the microcosm in the computer lab played a key role in the understanding of the very nature of this reaction.

In conclusion, we could say that it was difficult for the majority of the students to use micro scale systems, models and processes in their explanations. Their interaction with the micro scale world helped them to enhance their understanding of the chemical reaction, and this enabled them to associate macro scale processes with large-scale phenomena.

ABSTRACT

In Science teaching, laboratory work is recognized as one of the cornerstones. It can be successfully done with different methods of laboratory work. A previous research study of the influence on students´ knowledge of three different laboratory methods proved the connection between students´ leisure activities and better cognitive results for students. A group of 198 students of both genders from lower secondary school in Slovenia were chosen. These students, aged between 11 and 15 (5th to 9th grade), performed three Biology laboratory exercises (Activity of yeast, Gas exchange in breathing, Heart rate) as classic, computer-supported and virtual experiments. By using a pre-test and a post-test, we established the level of knowledge acquired in each exercise. With a questionnaire about leisure activities, we discovered that one of the most popular leisure activities, besides hanging out with friends, watching TV or listening to music, was playing on the computer; however, this did not contribute to higher levels of cognitive knowledge among students, neither did different laboratory methods. The most important factor leading to high cognitive levels of knowledge is students´ pre-knowledge.

Keywords: *Computer-supported laboratory, high cognitive levels, ICT, laboratory work, leisure, simulations*

INTRODUCTION

One of the active learning methods in Biology is laboratory work. With laboratory exercises and experimental work, we can achieve an understanding of many natural processes and empirical goals (Eschenhagen et al, 1998) which are less practicable or even unattainable with other education methods (Šorgo, 2007). With laboratory work students are actively included in the education process; they can create the process and in this way they can absorb more information for quality creation of knowledge (Luneta et al, 2007; Šorgo and Špernjak, 2007). Students in primary and secondary school (Šorgo and Špernjak, 2007) have a desire for active, creative and up-to-date laboratory work. Such laboratory work need not be limited to classic achievement; it can be strengthened with the application of information communication technology (ICT), where students, besides hand skills, can also develop computer competences (Špernjak and Šorgo, 2009). However, ICT in schools is mostly used for document creation, collecting information, for various methods of communication, or for using multimedia or virtual and real design biology laboratory work (Rogers and Wild, 1994; Strømme, 1998).

Higher education laboratory exercises have the potential not only to help students confirm theoretical knowledge, elaborate on it, and place it into a meaningful context, but also to help them learn scientific methodology and cultivate practical skills (Winberg and Berg, 2007). This is important not just for higher education but for all educational system. At the primary education level, the computer can be used on three different levels: for ‘basic computer skills’, ‘as an informational tool’, and ‘as a learning tool’ (Tondeur et al, 2007). Computers as a learning tool can be used in the laboratory for virtual or computer-supported laboratory work (CSL). With CSL, we have real results; conversely with virtual laboratory and computer simulation, the results are unreal (Kocijančič and O'Sullivan, 2004). In previous research we established that CSL and computer simulation can be included in biology laboratory work in primary school (Šorgo and Špernjak, 2007; Špernjak and Šorgo, 2009a). The major obstacles to incorporating CSL and computer simulation in primary schools are the teachers (Špernjak et al, 2009).

Yet the usage of ICT in Slovenian schools outside of specialized subjects like Computer Science or Informatics is welcomed but not obligatory for teachers. In existing teaching practice there exists an asymmetry with the expectations of students, who expect the teaching of biology to involve a mixture of interesting, multimedia-supported lectures with frequent laboratory and field work. In reality they most often get direct instruction intended to cover the textbook content in detail, with success on final examinations as the ultimate goal of education (Šorgo and Špernjak, 2007).

Unquestionably, ICT has had an impact on the quality and quantity of teaching, learning, and research in teachers’ and principals’ education (Moradi, 2009). Using ICT in schools can certainly offer interesting, topical and useful experience in education for both students and teachers. Graff (2003) and Mikropoulos et al (2003) claimed that students using ICT display effective mental processes and are more creative (Wheeler, 2002). The level of student knowledge is higher when using ICT than when using traditional educational techniques (Selinger, 2004), and students develop more key competences at the same time (Špernjak and Šorgo, 2009). Despite all the positive results of using ICT, up-to date technology should never replace teachers. Instead ICT should be a useful aid in education. We must seek the precise ratio between traditional ways of teaching and incorporation of ICT into education (Kubiatko and Haláková, 2009).

Computer usage in students´ leisure time

Research on children’s and youths’ use of technology in domestic settings is a growing field (Facer et al., 2001; Livingstone, 2003). One of reason is the growing cheapness and attainability of ICT equipment. In Slovenia there are more home computers every year. In 2003, 55 % of households owned computers, and in 2007 more than 66 % of Slovenian households had computers at home. Homes with children are better equipped with ICT than households without children. In 2007, as much as 77 % of households with children had access to the internet, compared to only 48 % of households without children (http://www.stat.si). Some researchers found that students use the home computers for different purposes than in schools (van Braak and Kavadias, 2005; Kerawalla and Crook, 2002; Livingstone, 2002; Meredyth et al., 1999; Ruthven et al., 2005; Selwyn, 1998; Somekh et al., 2002). One reason involves differing student interests, while computers in homes or in leisure clubs are more technologically advanced and offer a greater range of activities than those found in the normal classroom (Mumtaz, 2001).
To establish whether students of lower secondary schools who use computers during their leisure time develop higher levels of knowledge is one goal of our research. The other goals are to find the relation between students´ leisure-time intellectual activities (playing on the

computer, reading books, watching TV and studying school subjects) and the development of higher cognitive levels of knowledge.

Results will be targeted towards the development of a new generation of tested experiments and laboratory work to help teachers introduce active methods of teaching into their daily routine and the development of experiments to connect students' leisure time with school subjects.

METHODS

The pilot research was performed during summer school in 2008, with 198 students between 11 and 15 years of age. The fourteen-day summer school was performed on Krk, the largest Croatian island. Although the students were at the seaside, during the most intense heat of the day (between 1-3 p.m.), we arranged various activities. One of these was testing three different methods of Biology laboratory work. We used a pedagogical experiment with a questionnaire, a pre-test and a post-test.

In the test group were 25 (12.6 %) students in fifth grade, 33 (16.7 %) students in sixth grade, 52 (26.3 %) in seventh grade, 52 (26.3 %) in eighth grade and 35 (17.7 %) students in ninth grade. One (0.4 %) student left a field in the questionnaire blank, so we did not include this response in our analysis. To test the suitability of computer-based real and virtual laboratory, and to examine the differences among various styles of laboratory work, we prepared triplets of laboratory exercises. Each laboratory exercise in a triplet was prepared as classic laboratory work, computer-supported (real) laboratory work and interactive virtual laboratory work (computer simulations). In such a way, results were collected as 3x3 matrixes, which enabled us to search for differences between groups. Initially, we chose a well known and easy to perform laboratory exercise from current school practice. In the second phase this was adapted for computerized laboratory exercises. Vernier's interface, sensors and software (http://www.vernier.com) were used, but other acquisition systems would work as well. Interactive simulations were programmed in Microsoft's Visual Basic 6.0. Every simulation is a self-standing, auto-executive programme. The data obtained from computerized laboratory work were used to produce realistic graphs in interactive simulations developed for the purpose of the research.

The quality of knowledge produced by each method of laboratory work was tested by a pre-test and an equal post-test. For the pre-test, students received a questionnaire, where they ranked ten given activities from 1 to 10 according to their importance during the student´s leisure time. For each activity, they had to circle how much time per day they spent on it.

Description of laboratory exercises

Activity of yeast
This exercise is a standard one on account of its safety, the availability of materials and its potential for use at different points and contexts (rising of bread, fermentation, enzymatic activity, etc.) in teaching. The effect of temperature on the activity of yeast is examined. The speed of production of carbon dioxide is measured. In real experiments (both classic and computerized) a suspension of yeast obtained in a local store was prepared. A spoonful of plain sugar was added to the suspension. The suspension was divided into three bottles and put into water baths at different temperatures. Ice cubes were added to the first one, the second one stayed at room temperature, and the third was warmed to a temperature between 35 and 40°C. In the "classic" variant the rising of balloons indicates the speed of the reaction, in the computerized laboratory, the rise in gas pressure is measured using gas

pressure sensors, and in interactive simulation results are presented as graphs and flasks with balloons.

Gas exchange in breathing

The main goal of the exercise is to show that the composition of gasses in inhaled air is different from that in exhaled air. Oxygen is consumed in respiration and carbon dioxide is released. The differences are not constant but are in correlation with the activity. In the classical variant, a volunteer from each group exhales air through a straw into a sealed plastic bag with known volume. The exhaled air is poured into distilled water. Carbon dioxide forms a weak acid with the water, which results in a change of pH. The drop in pH can be registered with a pH meter or as a change in colour of bromthymol blue as an indicator. In the computerized version of the experiment, a volunteer exhales air into a plastic bag, and a gas oxygen sensor is used to record changes. Experiments can be repeated under other conditions (after some kind of activity) with the same or other volunteers. In interactive simulations, changes are presented as a drop in the concentration of oxygen in inhaled air and a rise of carbon dioxide in exhaled air.

Heart rate

The main task of the exercise is to examine differences in heart rate among students, changes caused by some sort of activity and the speed of recovery to an initial state. A stop watch is used to measure arterial pulse in the classical method; a heart rate monitor is used in the computerized laboratory. In simulations, students can choose between three different persons of varying gender (a student, a sportsman and someone overweight) and examine differences in heart rates before and after activity or between persons.

Pre-test and post-test

The quality of knowledge for each method of laboratory work was tested with a pre-test and an equal post-test. Students completed the pre-test before doing the exercises and the post-test after each exercise. The test for each exercise comprised tasks of factual knowledge, connection and use of knowledge, and tasks of high cognitive levels (solving new problems, independent interpretation and evaluation). The reliability test was done with Cronbach´s α. Cronbachs´ α for the Activity of yeast test was 0.84; for the Heart rate test Cronbachs´ α = 0.89, and for Gas exchange in breathing it was α = 0.74.

Microsoft® Excel 2007 was used for input data. Statistical analyses were done with the statistical package SPSS 17.0. One way ANOVA was used to examine differences between knowledge on the pre-test and on the pos-test. With multiple regressions we tested the influence of selected factors on results for knowledge at high cognitive levels.

RESULTS

The students´ leisure-time interests differ according to their gender.

With one way ANOVA, differences by gender for ten leisure activities were tested (Table 1). Not all students filled in the space for gender, and these were not included in the analyses. From Table 1 we can conclude that students´ most popular activities during leisure time, by gender, is hanging out with friends. In nine of the leisure activities there are no statistically significant differences by gender except in the case of reading books; girls are more likely to read books than boys ($F_{1, 188}$ = 7.42, (p = 0.01)).

Table 2: Popularity of leisure activities by gender; (1–most popular, 10–less popular).

Legend: No. = rank of activity popularity; N = number of students; M = mean; SD = standard deviation; SE = standard error.

Students´ most popular leisure-time activity is hanging out with friends. Their other activities are presented in Table 1.

Whether intellectual activities (watching TV, reading books, playing on the computer and studying school subjects) in leisure time influenced the development of high cognitive levels of knowledge can be seen in Tables 2 - 4. In the tests Activity of Yeast and Heart rate, one of six tasks was set at a high cognitive level. In the test Gas exchange in Breathing, two of nine tasks were at high cognitive levels. In Model 1 with multiple regressions we tested whether intellectual activities in leisure time contributed to better results on tasks requiring high levels of cognitive knowledge. In Model 2 we added some variables that may have influenced results for the same tasks. One of the variables is the school grade; however, for privacy reasons, we are denied the chance to test students' performance levels or intelligence, so we used the final school grade as one of the possible scales. In Slovenia final grades at the end of the year are compiled and students are recognized as excellent, very good, good, fair or failing.

In the test Activity of yeast the high cognitive levels question was, ˝Why is bread not sweet after baking although sugar is added before baking?˝ From the results in Table 2, we can see that none of selected intellectual leisure-time activities influenced in the development of high cognitive levels of student knowledge. The sole predictor of better student knowledge in the post-test was students´ pre-knowledge, which we established during the pre-test (β=0.22, p<0.001).

	Task 8 (pre-test)	0.18	0.07	0.21**	2.64
	Gender	-0.09	0.09	-0.09	-1.04
	Class	0.01	0.03	0.02	0.27
	School grade	0.02	0.05	0.04	0.44
Note: R^2 = 0.02 for Model 1: ΔR^2 = 0.06 for Model 2. ** p < 0.01, N = 169.					

In the Heart rate test the first high cognitive level question was, ˝ Why during strenuous physical activity or sport do we breathe through the nose and not through the mouth?˝ and the second: ˝We have been flown by helicopter to the top of Kredarica Mountain. On disembarking from the helicopter, we should be breathing faster. Try to explain why˝. From the results in Table 4, we can see that answer to the first question were influenced by watching TV (β=0.26, p<0.01), and by students´ pre-knowledge (β=0.33, p<0.001), but on the second question only the students´ pre-knowledge influenced the development of high cognitive levels of knowledge (β=0.21, p<0.01).

DISCUSSION

Few studies have examined the link between home computer usage and school achievement. One study from the USA (Attewell and Battle, 1999) indicates a connection between most school subjects and home-PC usage, even after correcting for socio-economic status. In our studies we did not examine students´ socio-economic status but just the popularity of leisure activities. Students have home access to internet surfing (Kuhlemeier and Hemker, 2007), but the question is: what are the content and goals of this internet surfing? According to our research, playing on the computer is not the dominant activity among students in lower secondary school; instead, hanging out with friends takes first place. This is not surprising because we are social beings and we need interactive relations and socialization.

In a Scandinavian sample of secondary school students, Leino (2003) found a positive relation between PC-usage and grades achieved in academic school subjects. He claimed that this relationship might be explained by the individual's level of literacy. Poor readers/writers did not do as well in most school subjects, and they used computers infrequently because this required reading/writing ability. In another study, Naevdal (2004) found that only school-relevant PC activities like information seeking and doing lessons predicted general school achievement; playing and chatting did not. The use of a home computer to obtain information and to handle text documents was obviously an advantage when it came to marks in English, independent of the total PC-time or of gender. These activities may be interpreted as regular school work, and work on school subjects at home usually improves school achievement (Nævdal, 2007). In general, if a student´s search topic on the computer were Science-related, they would have better results in knowledge. The question is not how knowledge is gained but the quality of the students´ knowledge. In Wills and McNaught´s (1996) research, we find a conclusion about the quality of knowledge acquired through classical and computer-supported learning. Students with traditional methods of education achieved better basic cognitive levels of knowledge (knowledge and understanding); meanwhile, students using computer-supported learning achieved better high cognitive levels of knowledge (analysis, synthesis and evaluation). We did not get similar results; the methods for different laboratory work (classic, computer-supported or computer simulation) do not contribute to higher cognitive levels of knowledge (Table 2-4). We also confirmed that using computers during students´ leisure time does not contribute to achievement of high cognitive levels of knowledge (Table 2-4). The same goes for other intellectual activities such as reading books or studying school subjects. In one case (the Heart rate test), watching TV did contribute to higher cognitive levels of knowledge (Table 4). We think that students may have been watching sporting events where they could have gained knowledge about breathing during activities. Gender, class and students´ school grades do not contribute to high cognitive levels of knowledge.

CONCLUSIONS

For the development of high cognitive levels of knowledge, what matters is the subject of all the leisure-time activities and previously-acquired knowledge but not the exercise methodology used in laboratory. Our results provide partial confirmation of Johnston (1997), Winberg and Berg, (2007), who emphasized the significance of pre-knowledge for effective laboratory based learning: ˝First-time, unprepared learners are not in a position to process laboratory experiences with understanding'' (p. 267), he wrote, claiming that what and how you learn is controlled by what you already know. The most important single factor influencing learning is what the learner knows. Ascertain this and teach accordingly (Ausubel, 1968).

ICT was included in education to facilitate the teaching, studying and training of students for quality use of ICT in later life (employment and social life). Gürbüz et al (2009) claimed that ICT influences students and teachers positively. In previous research (Špernjak and Šorgo, 2009b) we established that ICT in biology laboratory work is, for students aged 11 – 15, interesting, motivating and effectively just like classical methods of laboratory work. For the students´ benefit, it is a teacher´s duty to make a varied selection of pedagogical methods and good connections between subjects where students can make sense of pre- knowledge and later even attain high cognitive levels of knowledge.

ABSTRACT

This research aims to develop educational materials for teachers using *manga* as a support aid and to verify the materials' effectiveness. A practical evaluation was attempted targeting 83 second-year students at a women's college who were not specializing in science and who wished to become elementary school teachers, and 27 high school lab teachers specializing in science. The results show that both groups evaluated the *manga* as easy to read and as an effective method for understanding the characteristics of laboratory materials and for learning methods of instruction.

Keywords: *teacher education, narrative approach, manga, science materials, laboratory skills*

INTRODUCTION

The primary goal of teacher education is to cultivate teachers' qualities and capabilities and heighten their expertise in prospective teachers. The principles of Pedagogical Content Knowledge (PCK) are widely viewed as a model for these qualities and capabilities (e.g., Gess-Newsome & Lederman, 1999; Mishra & Koeher, 2006). PCK is knowledge directly linked to the teachers' practical abilities and expertise. In particular, in the field of science education, the understanding of laboratory equipment and materials and knowing how to use teaching tools effectively are essential practical abilities. However, in most cases in Japanese elementary schools, teachers who do not specialize in science are teaching science classes. Therefore, it cannot be said that their knowledge and understanding of laboratory equipment is sufficient. In fact, many elementary school teachers say that science is their weakness (Hanaue et al., 2009). This is why we have created teacher educational materials using *manga* as a tool to provide elementary school teachers with necessary science knowledge. *Manga* is a medium that enables the reader to understand content in a relatively short time. Important messages can be embedded into symbols, such as pictures or lines spoken by characters, making *manga* an ideal tool for learning materials that use the narrative approach as advocated by Yoshikawa (2007). Daikoku et al. (2009) developed *manga* educational material for teacher education in order to establish a cooperative learning method using this narrative approach, and they have confirmed its effectiveness. Therefore, this study developed *manga* educational material for teachers who are teaching science classes using the narrative approach, and then evaluated the material. The material was evaluated by students at a women's college who wish to become elementary school teachers but who have a weakness in science instruction, and high school science laboratory teachers who specialize in science. The evaluation of the *manga* educational material by both parties helps to more fully assess the effectiveness of the material for science teachers.

OVERVIEW OF *MANGA* EDUCATIONAL MATERIAL

The *manga* educational material examined here deals with instructions on using a hand crank generator (Figure 1) to learn about units of energy. The character of the teacher in the *manga* educational material is a woman. Since the majority of elementary school teachers

Figure 1: Hand crank generator

are women, it was believed that a female character would be easier to relate to.

Matsumoto et al. (2009) report that more than 70% of elementary schools do not have hand crank generators due to insufficient experiment equipment for physics education; therefore, it is assumed that teachers have little experience in using them in classes. Furthermore, college students aiming to become elementary school teachers have had very little science education in their elementary, middle, and high school years due to massive cutbacks in science education that stem from a relaxed education policy (yutori kyoiku); thus, they have little or no experience in using hand crank generators. The survey targeting 83 second-year students at a women's college who wish to become elementary school teachers revealed that 86% of them had no experience with hand crank generator experiments.

Implementation of hand crank generators in schools began in 1981. Currently, several different types of hand crank generators are used in science labs. The differences in the functions and usage of each type of hand crank generator are narrated using *manga*, along with actual classroom situations. Reading this *manga* educational material will enable teachers to not only learn in a simple way how to operate the generators or how to instruct students, but also to cultivate the ability to handle unexpected problems during class and to understand the structural characteristics of the experiment equipment and make appropriate judgments in various situations.

Instead of showing the phenomenon in which cranking the hand crank generator generates electricity and illuminates a miniature light bulb, Figure 2 shows a recognition of how the light differs among groups and how the miniature light bulb goes out due to excess voltage. There can be two causes for this. One is that the capacity of the hand crank generator exceeds the withstanding voltage of the light bulb. The other is that the teacher lacks a sufficient grasp of its capacity and cannot provide appropriate experiment instructions.

Then, there is the manner in which the teacher handles the situation when the light bulb goes out. The phrase “Oh! You too?” indicates that this is not the only group with a light bulb that is out, and the phrase “What should I do?” and the facial expression shows insufficient preparation for such a situation. This is because the teacher did not anticipate the light bulbs going out; in other words, the teacher was using a hand crank generator without having sufficient understanding of the relationship between the generator’s function and the experiment itself, and she did not have enough spare light bulbs to prepare for unexpected problems. In order to prevent such problems, in the *manga* educational material, product information for the hand crank generator is shown as modified to an appropriate voltage (approx. 3 volts) so that the miniature light bulb will not go out even if the generator is cranked rapidly. However, another point that must be derived from this series of scenes is that such trouble can be avoided if the teacher provides appropriate preliminary instructions and also pays sufficient attention to students during the experiment.

Figure 2: A scene from the *manga* educational material

Apart from the issue of the teacher’s instructional abilities, students often have a tendency to ignore study guidance and set procedures when they find the resulting phenomenon interesting or when they are intrigued by the differences between their experiment and that of someone else. Therefore, the development and improvement of experiment material with consideration of the characteristics of the students conducting the experiment as well as ease of operation is indispensable. However, this is not meant to compensate for the teacher’s lack of sufficient instructional ability. Rather, in the current school situation in which new and old experiment materials coexist, teachers who are able to provide appropriate instructions to students are called for more than ever.

Moreover, this *manga* educational material is designed so that science teachers with more experience and skills can gain deeper understanding. Take the example in Figure 3, where a teacher is lost in thought in the science lab. Shown behind the teacher is a shelf

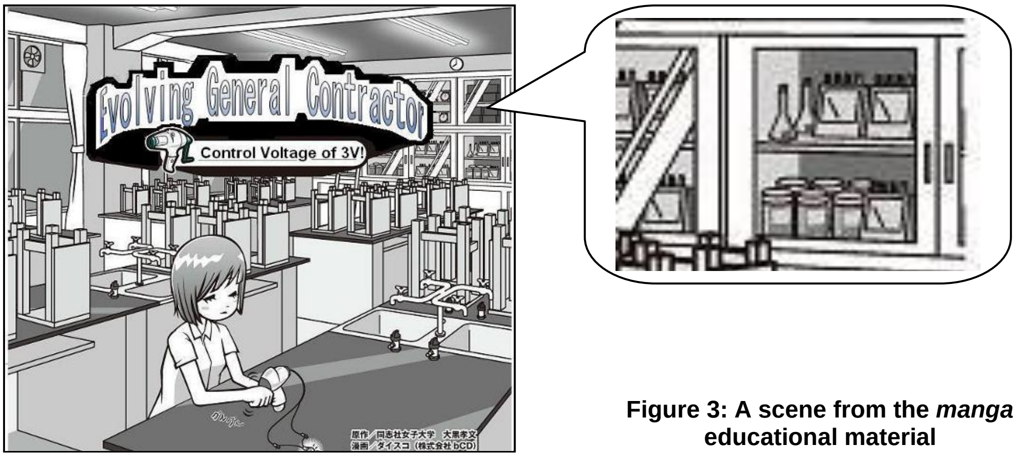

Figure 3: A scene from the *manga* educational material

containing experiment materials. To untrained eyes, this might seem like a well-organized shelf, but to teachers who teach in science labs, it is obvious that chemical experiment materials and electricity experiment materials should never be stored on the same shelf. Furthermore, people might tend to focus on the students conducting experiments in Figure 4, but experienced teachers will immediately realize that experiments dealing with weak light such as the miniature light bulb would never be conducted in a classroom where the curtains are not shut and the sunlight is streaming in.

In other words, issues with instructional skills and experiment skills are embedded as viewpoints in order to direct the readers’ focus to the ideas being conveyed; the amount of experience, knowledge, and skills that teachers have will affect what each teacher can gain from the *manga*. This indicates that *manga* educational materials can be highly effective in cultivating context adaptability and situation assessment ability.

Figure 4: A scene from the *manga* educational material

EVALUATION OF THE *MANGA* EDUCATIONAL MATERIAL

The evaluation in this study consisted of a questionnaire survey administered to 83 college students attending a private women's college in Kyoto Prefecture who want to become elementary school teachers but who do not specialize in science (conducted October 19, 2009) and 27 high school science laboratory teachers in Oita Prefecture (conducted November 13, 2009). The aim was to assess the effectiveness of *manga* educational material by having it evaluated by both college students who are weak in science instruction and laboratory teachers specializing in science.

EVALUATION 1: EVALUATION BY QUESTIONNAIRE SURVEY

Table 1 lists the survey questions. The survey content consisted of seven questions (1 to 7) on the "Ease of Reading *Manga*" and 17 questions on "Effectiveness of the *Manga* Educational Material." Within "Effectiveness of the *Manga* Educational Material," questions were asked about (1) understanding of functions and usage of experiment materials by the *manga* educational material (8 to 14), (2) comparison of explanations by the *manga* educational material and by conventional texts (15 to 18), (3) effectiveness of the *manga* educational material in depicting the functions and usage of experiment materials (19 to 22), and (4) effectiveness and expectations of the *manga* educational material for teachers with a weakness in science instruction (23, 24).

The results were analyzed based on a four-level rating method. For each question, answers were categorized into "Positive" and "Negative"; the tendencies of respondents were assessed using the exact probability test (both sides).

EVALUATION 2: EVALUATION BY FREE WRITING

Table 1: Questions regarding *manga* educational material

[Ease of Reading *Manga*]

1 Students can relate to the character design in the *manga* educational material.
2 The *manga* educational material is easy to continue reading.
3 The way in which frames progress in the *manga* educational material is easy to understand.
4 The text of the *manga* educational material is easy to read.
5 The amount of text in the *manga* educational material is appropriate.
6 The *manga* educational material accurately depicts the experiment materials, lab equipment, etc.
7 The *manga* educational material accurately depicts actual classroom situations.

[Effectiveness of the *Manga* Educational Material]

(1) Understanding of functions and usage of experiment materials by the *manga* educational material

8 The *manga* educational material aids in understanding the functions of educational material.
9 The *manga* educational material shows the usage of experiment materials in an easy-to-understand manner.
10 The *manga* educational material shows the problems with using experiment materials in an easy-to-understand manner.
11 The *manga* educational material shows the development concept of experiment materials in an easy-to-understand manner.
12 Even when teaching students how to use the experiment materials after reading *manga* educational material, there are times when desirable experiment results are not achieved, depending on the characteristics of the experiment materials.
13 After reading the *manga* educational material, I understand why the experiment material needed to be improved.
14 Because I understood why the experiment materials needed improvement after reading the *manga* educational material, I know what I need to watch out for when providing experiment instruction, even when I'm using outdated experiment materials.

(2) Comparison of explanations by the *manga* educational material and by conventional texts

15 The *manga* educational material helps me understand the function of the experiment materials better than plaintext.
16 The *manga* educational material explains how to use the experiment materials better than plain text.
17 The *manga* educational material shows the problems with using experiment materials better than plain text.
18 The *manga* educational material explains the development concept of experiment materials better than plain text.

(3) Effectiveness of the *manga* educational material in depicting functions and usage of experiment materials

19 I think it is effective to use the *manga* educational material to explain the functions of the experiment materials.
20 I think it is effective to use the *manga* educational material to better explain how to use the experiment materials.
21 I think it is effective to use the *manga* educational material to better show the problems with using the experiment materials.
22 I think it is effective to use the *manga* educational material to better explain the development concept of the experiment materials.

(4) Effectiveness and expectations of the *manga* educational material for teachers with a weakness in science instruction

23 I think it is effective to use the *manga* educational material for teachers with a weakness in science experiments.
24 If other *manga* educational material introducing_other experiment materials exists, I would like to read it.

Second-year college students were asked to answer freely on the “Effectiveness of the *Manga* Educational Material.” Their answers were reviewed based on the four perspectives related to “Effectiveness of the *Manga* Educational Material.”

RESULTS AND CONSIDERATION

EVALUATION 1: RESULTS AND SPECULATION OF QUESTIONNAIRE EVALUATION

Table 2 shows the results of the questionnaire. In both groups of college students and laboratory teachers, the numbers of positive answers for almost all questions were significantly larger ($p<0.01$). To compare the two groups, each question was assessed using the chi-square test. No differences existed for any questions regarding ease of reading or effectiveness. This suggests that both groups felt the same way about ease of reading and effectiveness.

Regarding “Ease of Reading *Manga*,” the above results show that the *manga* with its characters and lines is easy to relate to and read. This can be understood as the result of the careful design of the *manga* educational material to target female teachers, who comprise the majority of elementary school teachers.

As for “Understanding of functions and usage of experiment materials by the *manga* educational material,” a positive evaluation was given on all questions. In particular, the reason why the experiment material was improved was understood by almost everyone. This can be considered the achievement of one of the goals of this educational material, which is to explain the reason behind the development of experiment material.

Table 2: Questionnaire results

No.	College students			High school science laboratory teachers		
	Positive	Negative	SS	Positive	Negative	SS
1	82	1	**	22	5	**
2	73	10	**	26	1	**
3	71	12	**	27	0	**
4	73	10	**	27	0	**
5	83	0	**	23	4	**
6	53	30	*	20	7	*
7	71	12	**	24	3	**
8	71	12	**	21	6	**
9	60	23	**	20	7	*
10	62	21	**	23	4	**
11	65	18	**	21	6	**
12	68	15	**	26	1	**
13	80	3	**	26	1	**
14	67	16	**	26	1	**
15	80	3	**	25	2	**
16	76	7	**	25	2	**
17	78	5	**	24	3	**
18	74	9	**	24	3	**
19	79	4	**	27	0	**
20	81	2	**	27	0	**
21	83	0	**	27	0	**
22	78	5	**	26	1	**
23	81	2	**	24	3	**
24	80	3	**	23	4	**

**$p<.01$ *$p<.05$

Regarding "Comparison of explanations by the *manga* educational material and by conventional texts," all answers proved the effectiveness of the *manga* educational material. This is due to the characteristics of the *manga* material itself: it is easy to understand and a comparison of the context can be easily done by looking backward or forward to other frames.

A high evaluation was received for all questions regarding “Effectiveness of the *manga* educational material in depicting functions and usage of experiment materials” as well, especially for the question of whether or not issues regarding usage of experiment materials are easy to understand, to which everyone answered positively. It is likely that this is due to the successful implementation of the narrative approach, which allows readers to recognize problems by building them into the story of the *manga*.

Lastly, regarding “Effectiveness and expectations of the *manga* educational material for teachers with a weakness in science instruction,” almost everyone acknowledged its effectiveness and said that they would like to read more new *manga*. This can be interpreted as readers empathizing with the teacher in the *manga*, who is not good at science instruction.

There was no difference in the evaluation by the two subject groups. This indicates that the validity of the *manga* educational material was confirmed, since experiment teachers specializing in science gave high evaluations, and also that this *manga* educational material is an effective teaching method for teachers who have a weakness in science instruction.

EVALUATION 2: RESULTS AND SPECULATION OF FREE WRITING EVALUATION

Table 3 shows representative examples of free writing answers by college students with a weakness in science instruction, based on the four perspectives of “Effectiveness of the *Manga* Educational Material.”

(1) Understanding of functions and usage of experiment materials by the *manga* educational material

Many of the free writing answers mentioned experimental material, usage, and method of instruction; this indicates that students were able to read through the material with an awareness of the relationship between the material and classroom instruction.

(2) Comparison of explanations by the *manga* educational material and by conventional texts

In free writing answers, the difference in the method of conveying information between text and *manga* was mentioned. This indicates that students were able to compare and contrast the context by looking backward or forward to other frames, enabling them to easily recognize the causal connection of problems that occur.

(3) Effectiveness of the *manga* educational material in depicting the functions and usage of experiment materials

From the expression “hidden traps were very difficult to find” found in the free writing answers, it can be seen that the narrative approach that allows readers to recognize problems by reading into the story of the *manga* is working effectively. In addition, the evaluation stating that “it can be read over and over again” also shows a characteristic of the *manga* educational material.

(4) Effectiveness and expectations of the *manga* educational material for teachers with a weakness in science instruction

As can be seen from the free writing answers, for students with a weakness in science instruction, *manga* educational material can be an effective method for conveying information. Also, the reading of *manga* can be interpreted as a willingness to improve as a science teacher.

This shows that the *manga* educational material was evaluated as effective by college students with a weakness in science instruction. It suggests that *manga* educational materials can be an effective tool to help teachers who are weak in science understand the characteristics of experiment materials and learn methods of experiment instruction.

CONCLUSION

Table 3: Examples of free writing answers by second-year college students

(1) Understanding of functions and usage of experiment materials by the *manga* educational material
− In a real classroom setting, it was easy to get into. Characteristics of hand crank generators were easy to understand with *manga*. − What to watch out for when conducting experiments, and what exactly was improved were very easy to understand. How to use it was a little difficult to understand.
(2) Comparison of explanations by the *manga* educational material and by conventional texts
− What I couldn't understand before with just instructional text became easier to understand with *manga*. When the miniature light bulb went out after students cranked the generator too hard, at first I thought the generator broke, but after I kept reading, I understood that the voltage became too high. − I didn't feel much like reading the first pamphlet (manual) I saw, so the difference between the new and the old hand crank generator was difficult to understand, but the *manga* made it easy.
(3) Effectiveness of the *manga* educational material in depicting functions and usage of experiment materials
− The *manga* educational material was easier to relate to than text, and was more interesting. Also, I thought the *manga* educational material was intriguing because one could read it over and over again. I'd like to read more such *manga* educational material in the future. − Unlike text, *manga* allowed easy understanding of the contents, and made learning fun. But, although fun, this enjoyable *manga* had many hidden traps, which were very difficult to find.
(4) Effectiveness and expectations of the *manga* educational material for teachers with a weakness in science instruction
− Text is often not enough to explain certain things; therefore, I think this *manga* educational material is very useful. I think it can be very effective in practical situations, and I myself would love to read more. − Very easy to understand. I am not good at science and have anxieties about whether I can teach students adequately, so I would like to read such *manga* when I become a teacher. I would like to have easy-to-understand explanations of the traps hidden in the *manga* attached at the end, too.

This study developed teacher educational material using *manga* to support science teachers, and evaluated its effectiveness. *Manga* is a medium that allows readers to follow a story in a relatively short time, and it allows the creators to embed important messages in the drawings and spoken lines. In the *manga* educational material dealing with how to provide usage instructions for hand crank generators, the problems in instruction skills and experiment skills were narrated in order to focus on the important messages.

The effectiveness of the *manga* educational material was evaluated by both college students with a weakness in science instruction and experiment teachers specializing in science. Both groups provided high evaluations, indicating that the *manga* educational material is an effective educational tool for science teachers. The results of this research demonstrate the possibility of using *manga* for teacher education.

In the future, we would like to continue this development in order to realize a more effective utilization of *manga* educational material, such as creating teachers' manuals and case study programs.

ABSTRACT

In order to build a sustainable society, there is a need for the development of human resources who can deal with unsolved sustainability issues and related environmental issues. First, this paper examines differences between the human resources developed through conventional education and through sustainability education. Second, this paper discusses the core competencies required for the sustainability education and introduces our educational challenges in Japan.

Keywords: *sustainability education*, *skills*, *mind*, *knowledge*

INTRODUCTION

In order to build a sustainable society, there is a need for the development of human resources who can deal with unsolved sustainability issues and related environmental issues. When defining the human resources desired, we must clarify what core competencies are required of these resources. Asking what capabilities should be acquired is a question essential to human resource development, one that enables us to share a specific vision of the human resources desired, and also provides clues for the implementation of this vision in practical education. Therefore, alongside education for sustainable development (ESD), which has grown in popularity internationally in recent years (see, e.g., UNESCO, 2005, 2007), there is a need for education that can provide a comprehensive understanding of the global, social, and human systems and their interrelationships, which are regarded as the essential components of sustainability science (Komiyama & Takeuchi, 2006). For example, in the context of climate change issue caused by the mutual contradiction between global and social systems, the role of human resource development is significant. Education or capacity development may reduce the adverse effects of climate change.

In Japan, the five participating universities (University of Tokyo, Kyoto University, Osaka University, Hokkaido University, and Ibaraki University) in the Integrated Research for Sustainability Science (IR3S) are collaborating on the educational program that can nurture specialists who can make an active contribution to the construction of a sustainable society on the global stage (Figure 1). For instance, the Graduate Program on Sustainability Science (GPSS) in Ibaraki University, which has started on April 2009, is an interdisciplinary program intended to produce specialists in sustainability science who will contribute, domestically and internationally.

This paper discusses the core competencies required of the sustainability education and introduces some challenges for the human resource development. This paper mainly focuses on the activities for sustainability education in Japan. For the discussion and activities about the other countries, see, e.g., Segalàs et al (2009).

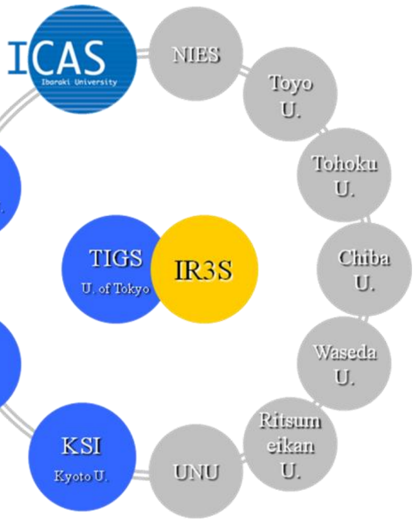

Figure 1 I Integrated Research for Sustainability Science (IR3S)

GOALS FOR HUMAN RESOURCE DEVELOPMENT

Table 1 summarizes the differences between human resources required in conventional education and sustainability education in the case of Japan. Conventional education in Japan has largely focused on the accumulation of knowledge. This tendency is particularly prominent in higher education (see, e.g., Central Council for Education, 2003). Undergraduates and graduates dedicate themselves to the acquisition of segmented expertise by taking specialized and segmentalized courses from the time they enter universities and graduate schools. Conventional undergraduate and graduate education has adopted this approach because the main goal of this education is to impart expertise. The root of this tendency is, no doubt, a presumption that higher education best serves society by producing human resources who are specialists who can apply the latest specialized knowledge in specific fields.

However, the fundamental issue addressed by sustainability science is how to reconstruct the global, social, and human systems into appropriate forms in order to establish a sustainable society, based on a recognition that there are mutual contradictions among these three systems. Therefore, the human resources trained by sustainability education must have in their minds a long-term vision for building a sustainable society and must acquire competencies that can contribute to solving the problems that are actually occurring in various areas of society.

The following characteristics of human resources fostered by sustainability education can be identified: (1) their activities are problem-oriented rather than discipline-oriented; (2) their field of action is envisioned as a broad field embracing various occupations as well as various activities appropriate to diverse social perspectives but sharing the goal of building a sustainable society; and (3) students belonging to any discipline may be candidates for sustainability education.

Figure 2 summarizes the desired competencies for the above human resources (Tamura & Uegaki, 2010). In addition to expertise, sustainability education requires comprehensive competencies that combine holistic knowledge, skills, and mind.

Holistic knowledge mainly helps provide human resources with the competency to detach and position themselves. In other words, this competency enables the students to (1) place their own accumulated experiences and knowledge in a larger context, thereby defining their positions, and (2) identify the issues to be dealt with.

Required skills are divided by three components: (1) Communication skills. This includes the ability to understand the emotions of others, see perspectives other than one's own, and build relationships with others. Whether taking a local or global perspective, it is necessary to cooperate with different people with different viewpoints in order to actually resolve problems. (2) Collaboration skills. These are skills in building relationships using communication skills and linking these relationships with various other related factors. With the complex and all-encompassing challenges involved in attaining a sustainable society, the ability to link individual problems to other problems and recognize patterns is critical. Collaboration skills also include the ability to recognize the relationships between different activities occurring at the same time and to bring together the various stakeholders involved. (3) Problem-solving skills. Unlike the ability to link factors or build relationships, which are germane to dealing with individually occurring problems, problem-solving skills include the ability to single out problems and find clues for their resolution. Because efforts to achieve sustainability include a variety of actors, conflict can arise even when care is taken to avoid it. While communication skills can help to prevent conflict before it occurs, problem-solving skills enable us to manage unavoidable conflicts in the best manner possible.

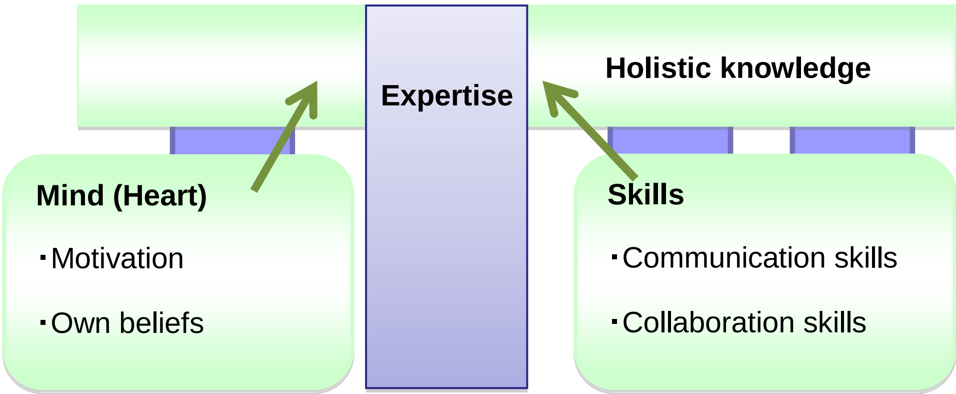
Mind as envisioned here includes the following elements: (1) Motivation. This refers to the mental strength and endurance to bring to completion actions that are initiated. (2) One's own beliefs. A new activity often runs into failure or barriers of some sort. Maintaining one's motivation without giving up requires a strong belief in or rationale for one's own practice. (3) Synchronic consciousness. This is the competency of not being restricted to narrow personal relationships, but rather being able to imagine people around the world in situations different from one's own and striving to communicate with them. This also refers to the ability to expand one's sphere of activity even when in unfamiliar areas or foreign countries. (4) Diachronic consciousness. Behind the ability to motivate people, raise awareness of a problem into a belief, and refine the sensibilities of others sharing the same epoch, is an omnipresent love expressed toward the existence of other individuals and other generations.

Finally, these should be combined with the expertise that is emphasized in conventional education. The human resources we seek to develop should acquire their own core expertise and additionally acquire the specific competencies required for sustainability science. In other words, by learning holistic knowledge and expertise in addition to mind (including motivation, one's own beliefs, and synchronic/diachronic consciousness) and skills (including communication skills, collaboration skills, and problem-solving skills), these human resources will be prepared to discover, identify, and take steps to resolve sustainability issues on their own.

Table 1 Differences between human resources required in conventional education and sustainability education

	Conventional education	Sustainability education
Orientation for action	Discipline-oriented	Problem-oriented
Field	Field in which students can make use of their expertise; specific job descriptions	Local to global fields; various job descriptions
Target	Students who belong to specific faculties, or candidates seeking expertise in specific academic fields	Students who belong to all fields and candidates seeking expertise in various areas of knowledge who also aspire to help build a sustainable society

Figure 2 Core competencies for human resources fostered by sustainability education



CHALLENGES IN JAPAN

Ibaraki University launched its Graduate Program on Sustainability Science (GPSS) in April 2009 (For the other Japanese programs for sustainability education, see, e.g., Onuki & Mino, 2009; Uwasu et al., 2009). Figure 3 shows an outline of this education program. An interdisciplinary program, it is designed for postgraduates and is composed of the Sustainability Science Course and the Sustainability Science Program. The Sustainability Science Course is one of the regular master's courses of the Urban System Planning Course of the Graduate School of Science and Engineering. The Sustainability Science Program is composed of minor courses offered by all graduate schools of Ibaraki University (Humanities, Education, Science and Engineering, and Agriculture). In the case of the Sustainability Science Course, subjects are included in the regular curriculum (a total of 30 credits must include 6 credits from Basic Subjects and 2 credits from Practical Subjects), and students earning the required units of credit will receive a Certificate of the Sustainability Science Course in addition to their master's degree. In the case of the Sustainability Science Program, students can receive a Certificate of the Sustainability Science Program once they have fulfilled the requirement of 6 credits from Basic Subjects or Practical Subjects and 4 credits from Specialized Subjects authorized by the respective graduate schools (this requirement differs slightly depending on the graduate school).

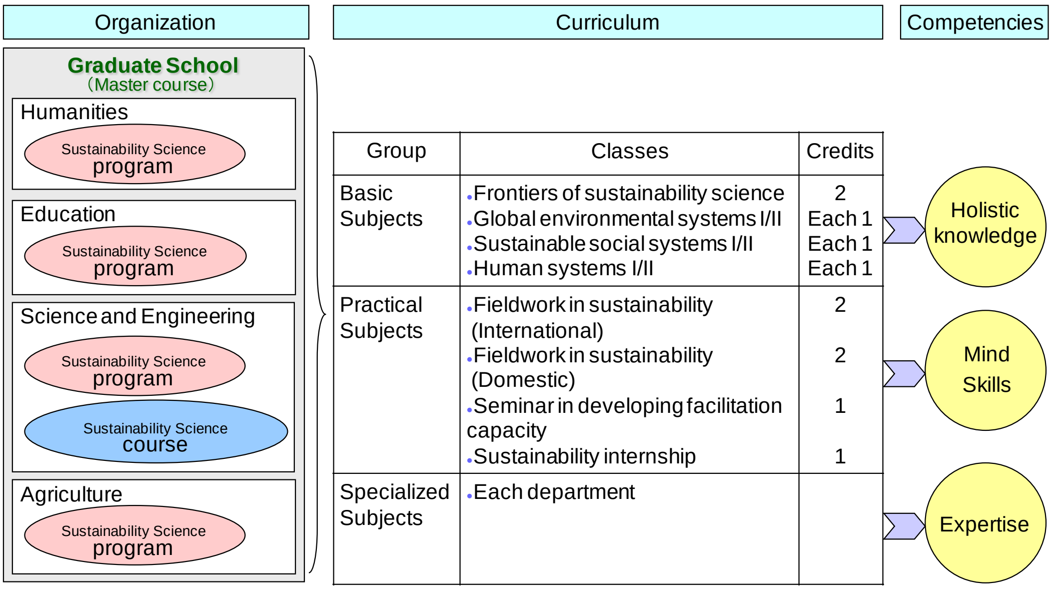
These courses aim to develop not only advanced expertise but also the following three different competencies. The first competency is holistic knowledge of the broad range of issues associated with sustainability science, so as to enable students to adopt different viewpoints as well as position their own expertise in various fields. The second is the development of communication skills to enable students to understand others and form relationships, collaborating skills to encourage various stakeholders to address issues, and problem-solving skills to identify real issues and resolve conflicts. The third is “mind” or “heart,” which includes the motivation to dedicate oneself to the public, having one’s own beliefs to maintain that motivation, and synchronic/diachronic consciousness.

The education model can be referred to as “Education across Mind-Skill-Knowledge” (Shin-Gi-Chi in Japanese). This is an analogy derived from a proverb about traditional Japanese sports that defines Shin-Gi-Tai as the three elements essential to being a great athlete. Shin-Gi-Tai expresses the need in competitive sports for a comprehensive foundation combining physical ability (Tai = body), sophisticated athletic skills (Gi = skill) and sound mind (Shin = mind). The replacement of Tai with Chi (knowledge) yields the expression Shin-Gi-Chi: “Mind-Skill-Knowledge.”

In order to achieve this objective, the curriculum is composed of three main categories. First, Basic Subjects for holistic knowledge aim to help students understand the structures of the global system, social system, and human system, and consider the interactions among these systems from an integrated viewpoint. Second, Practical Subjects aim to nurture the skills and mind needed to work in international or domestic fields where students will experience complex problems, and must communicate and work with people living with those problems. Lastly, Specialized Subjects are offered with the expectation that recipients of sustainability education need expertise in a real field of specialization to which they can commit themselves.

Ibaraki University anticipates that graduates who finish this education program will be equipped to contribute both locally and globally in such fields as government, business, education, international organizations, NGOs and NPOs.

In 2009, as a result, the number of graduate students who registered for and took this educational program numbered 45 for the Sustainability Science Program and 4 for the Sustainability Science Course, for a total of 49 students. This greatly exceeded our original expectations.



Group	Classes	Credits
Basic Subjects	･Frontiers of sustainability science ･Global environmental systems I/II ･Sustainable social systems I/II ･Human systems I/II	2 Each 1 Each 1 Each 1
Practical Subjects	･Fieldwork in sustainability (International) ･Fieldwork in sustainability (Domestic) ･Seminar in developing facilitation capacity ･Sustainability internship	2 2 1 1
Specialized Subjects	･Each department	

Figure 3 Graduate Program on Sustainability Science at Ibaraki University

IMPLEMENTATION OF PRACTICAL SUBJECTS AND EVALUTATION

The Practical Subjects are one of the essential components of the education program. In 2009, the program initiated an international fieldwork seminar (Fieldwork in Sustainability) at Mai Khao village in Phuket, Thailand. Additionally, a domestic fieldwork seminar deals with issues in Oarai City, in Ibaraki Prefecture. Through the group works and discussion between students and people in the site, these fieldworks particularly contributed the education for mind and skills.

'Fieldwork in Sustainability (International)' was implemented in the field at Mai Khao, in Phuket, Thailand from August 22 to 30. Four teaching staffs and 12 graduate students went there from Ibaraki University. They were joined by some teachers and 13 students from Phuket Rajabhat University. In the field, the graduate students from both schools were divided into four groups: a Rice Paddy-Agriculture Team, a Waste-Garbage Team, a Turtle-Biological Conservation Team and an Afforestation Team. Each team drafted a research plan, carried out field investigation and brought their results together and put on a poster. The finished poster introduced the people of Mai Khao village and shared opinions. By working together to complete the poster as well as communicating with the villagers, students in different countries and different graduate schools, though they were from many backgrounds and nationalities, the students were able to work proactively to understand the problems, discover the issues and seek solutions. From this experience, not only was there an increase in the desire to study and learn English, there was also a feeling of accomplishment, a sense of fulfillment and a definite change in level of motivation. On the other hand, the solutions shown in the fieldwork were inadequate, but we hope that with the further accumulation of results, we will see developments from next year on.

For 'Fieldwork in Sustainability (Domestic)', we held a preliminary briefing, listening to a lecturer on September 11. Then from September 12 to 13, we did fieldwork in Oarai, Ibaraki. 20 graduate students took part. Over the two days, they did field surveys and had discussions on four main themes: Coastal Ecology and Clams, Coastal Development and Recreational Beaches, The Water Environment of the Naka River and Lake Hinuma, and Fresh-water Clam Digging and Lake Hinuma. Furthermore, a follow-up discussion was held on September 25. Local knowledge was exchanged and research results were shared. An overall theme of 'How to construct the city using water environment' was put forth, and the results were put on posters by groups.

Just as with 'Fieldwork in Sustainability (International)', students from a variety of backgrounds could proactively understand problems and have the motivation to discover issues and seek solutions through the cooperative work. In the process, they cultivated a desire for learning and an attachment to the field. The preliminary briefing also contributed to the liveliness of the local hearing. Having a workshop to bring the research results of all the various themes together was a good way to develop the ability to form a holistic viewpoint of the field.

Questionnaire surveys of the students were implemented before and after the fieldwork. The questionnaire is divided by qualitative and quantitative one. The former is description of their feelings and comments. One of the significant differences between before and after the fieldwork was the volume of students' description. Most of the students wrote more than before because they learnt many things from the fieldwork. The latter is self-evaluation of their abilities and competencies. They evaluated their scores of abilities from 1 to 5.

Table 2 shows the result of self-evaluation. Most of the components increased after the participation in both International and Domestic fieldwork. On the other hand, some abilities such as interdependence decreased after the fieldwork. During the group work and discussion, students might recognize both possibility and limit of their own abilities. Of course, it should be prudent to examine the results of self-evaluation. However, it is obvious that these Practical Subjects contributed for the students to acquire skills and mind, which are the important competencies for the sustainability education.

Table 2. Self Evaluations for the Students

Fieldwork in Sustainability (International) (*n*=12)

		Before fieldwork (average)	After fieldwork (average)	Difference
Independence	Self responsibility	4.5	4.3	-0.2
	Positiveness	4.6	4.6	0.0
Motivation	Receptivity	4.0	4.0	0.0
	Self-reform	3.8	4.4	0.7
Action	Continuation for the belief	4.0	4.0	0.0
	Responsibility for the results	4.2	4.3	0.1
Sociality	Contribution to the groups	3.9	4.2	0.3
	Contribution to the society	3.8	3.8	0.1
Communication skill	Ability to guess	3.8	3.9	0.1
	Team work	3.8	3.8	-0.1
Thinking faculty	Structural understanding	3.9	4.1	0.2
	Logical understanding	3.4	3.8	0.4

	Imagination	3.6	3.8	0.2
Managing ability	Ability to analyze	3.7	4.2	0.5
	Ability to correspond	3.8	4.0	0.3

Field Work in Sustainability (Domestic) (*n*=20)

		Before fieldwork (average)	After fieldwork (average)	Difference
Independence	Self responsibility	4.2	4.1	-0.1
	Positiveness	4.4	4.2	-0.2
Motivation	Receptivity	4.3	4.4	0.1
	Self-reform	3.9	4.1	0.2
Action	Continuation for the belief	3.7	3.7	0.0
	Responsibility for the results	3.8	3.7	-0.0
Sociality	Contribution to the groups	3.8	4.1	0.3
	Contribution to the society	3.5	3.5	0.1
Communication skill	Ability to guess	3.7	4.2	0.5
	Team work	3.7	4.4	0.7
Thinking faculty	Structural understanding	3.3	4.3	1.0
	Logical understanding	3.5	3.7	0.3
Planning ability	Collection of the information	3.7	3.9	0.2
	Imagination	3.4	3.7	0.3
Managing ability	Ability to analyze	3.8	4.1	0.3
	Ability to correspond	3.4	3.9	0.6

CONCLUSION

This paper firstly examines differences between the human resources developed through conventional education and through sustainability education. Secondarily, this paper discusses the core competencies required for the sustainability education and introduces our educational challenges.

The aim of sustainability education is to develop human resources with different specialties who, from various social backgrounds and various perspectives corresponding to their individual situations, can share a long-term and comprehensive perspective toward the construction of a sustainable society. Through sustainability education, these human resources will be expected to work toward solving actual problems while building collaborative relationships with a broad diversity of actors.

ABSTRACT

The purpose of this study is to examine the effect of cooperative learning on students' understanding of reaction rate in 11th grade chemistry course. 110 students participated in the study. The participants were selected from two different schools. Two classes from each school were included. One of the classes in each school was randomly assigned as a control group instructed by traditional way and the other as an experimental group instructed by cooperative learning. Reaction Rate Concept Test (RRCT) was given to measure students' understanding of reaction rate. In addition, Science Process Skill Test (SPST) was administered before instruction to decide whether there was a significant difference between two groups in terms of their science process skills. At the end of the instruction, there was a significant mean difference between the experimental and control group students' performances. According to the results of RRCT and interviews, cooperative learning removed most of students' misconceptions about reaction rate concept and so brought about a significantly better understanding of reaction rate compared to traditional instruction.

Keywords: *Cooperative learning, misconception, reaction rate*

INTRODUCTION

Abstract concepts are difficult for students to comprehend. Therefore, it is necessary to be aware students' misconceptions and develop proper teaching strategies having regard to them. Research studies indicated that students have great difficulties in understanding reaction rate. For example, Kousathana and Tsaparlis (2002) examined 17-18 aged students' errors while solving numerical-chemical equilibrium problems in an elective course. According to the results, majority of the students could not understand that reaction rate and reaction yield are different concepts and they are not directly related to each other. Many students expressed the following misconception: "*Rate of reaction means the same as extent of reaction*", that it is also supported by Griffiths (1994). Kousathana and Tsaparlis (2002) also concluded that students applied Le Chatelier's principle to rate of reaction concept. Several students thought that if the reaction is thermoneutral (neither endothermic nor exothermic) the rate of reaction is not influenced by a change in temperature in line with Le Chatelier's principle. There is a hidden misconception here: "*heat is evolved or absorbed only in the cases that heat is explicitly involved (that is, shown) in the chemical equation ("thermochemical" equation*) (p. 14).

In another study, Garnett, Garnett and Hackling (1995) investigated 17-19 years old students' understanding of chemical kinetics and found the following misconceptions:

- "The forward reaction rate increases as the reaction 'gets going'" (p. 81).
- "The forward reaction rate always equals the reverse reaction rate" (p. 81).
- "The forward reaction is completed before the reverse reaction commences" (p. 81).

Çakmakçı (2005) examined secondary school and undergraduate students' conceptual understandings of chemical kinetics. The study indicated that though most of the school students knew the factors affecting reaction rate (e.g. temperature, concentration, catalysts), many of them did not agree that volume or pressure are factors affecting rate of reactions in gas phase. Some students used the terms of concentration and number of moles interchangeably. A misconception held by students is the rate of a reaction is directly proportional to the concentration of reactants. They did not consider the order of the reaction. Other results showed that students could not interpret the graphs related to the factors affecting reaction rate. Also, they had difficulty in understanding the fact that the rate of a reaction must be determined experimentally.

Cooperative learning is a suitable strategy to deal with the misconceptions and improve students conceptual understanding of abstract concepts (Acar & Tarhan, 2008; Basili & Sanford, 1991; Slavin, 1987). It requires students to work together in small groups to support each others' learning and understanding and to accomplish shared goals. The research studies suggest that successful cooperative learning needs to provide following elements to increase students' efforts to achieve, and to improve their interpersonal relationships: positive interdependence, face to face promotive interaction, individual accountability, social skills and group processing (Johnson & Johnson, 1975; Johnson, Johnson, Holubec & Roy,1990). When *positive interdependence* is obtained, students will understand that each member's contributions are crucial and each member has a unique contribution to help the group achieve its goals. *Face to face promotive interaction* exists when students work in small groups where they can see each other so that they can engage in face-to-face discussions about their tasks. *Individual accountability* implies that each group member is responsible for his/her own contribution, free-loading is not tolerated and everyone must contribute. For *social skills* to be established, students need to be taught how to communicate efficiently with each other to know how to express their ideas, acknowledge contributions of others, deal with discrepancies, and manage conflicts. *Group processing* is a kind of formative assessment including students' reflections on how they are managing the process of learning and what they may still need to do to reach their goal. Group members discuss how well they are reaching their goals and maintaining effective working relationships with each other.

Teachers can guide learning of students having different backgrounds by creating an environment in which they are actively involved in their learning. Cooperative learning, which is based on constructivism, is one of the proper methods satisfying this goal. When students work in cooperative groups, they more frequently use higher levels of reasoning and critical thinking skills to create new ideas and solutions compared to competitive and individualistic situations (Johnson & Johnson, 1999). Furthermore, Johnson and Johnson (1987) found out that when cooperative learning approach was used more in the classroom, students would learn science better, they would tolerate the differences more and value themselves more as science students.

Correspondingly, following research questions were investigated in the present study:

1. Is there a significant mean difference between 11^{th} grade students who are taught by cooperative learning and traditionally designed instruction in terms of their understanding in reaction rate when the effect of science process skills is controlled as a covariate?
2. What are 11^{th} grade students' conceptions about reaction rate?

METHODOLOGY

Sample

One hundred and ten 11th grade students were involved in the study since the concept of reaction rate was taught at this grade level. The students were from two different schools, one of which was a high school and the other was an Anatolian high school. Students of Anatolian high school were accepted to that school through a nationwide exam while the high school has no academic selection criteria; therefore, they were brighter than the students of high school. The researchers picked two classrooms randomly from each school since it was not possible to assign students to experimental and control group one by one randomly. One class was assigned randomly as experimental group and one class as control group in each school. Correspondingly, experimental and control group involved 56 and 54 students, respectively.

Two teachers, one in each school, taught related chemistry content. They had nine and 11-year-teaching experience and similar chemistry content background. Both teachers took experimental and control group.

Instruments

Reaction Rate Concept Test (RRCT)
RRCT, developed by the researchers, is composed 16 two-tier items and 7 multiple choice items in Turkish. A two-tier question involves two parts. First part includes three or four alternatives. In the second part, students are expected to provide their reason for the answer given in the first part by selecting among four alternatives. These alternatives are constructed based on students' misconceptions (Treagust, 1987). Therefore, the alternatives of the two-tier items and multiple choice items in RRCT were prepared by considering students' misconceptions revealed by some studies (Haim, 1989; Garnett et al., 1995; Nakiboğlu, Benlikaya & Kalın, 2002; İcik, 2003; Bozkoyun, 2004; Çakmakçı, 2005; Balcı, 2006; Kıngır & Geban, 2006). Each item was assessed by four chemistry educators and two chemistry teachers to check its content validity, accuracy, and format. The test covered rate of reactions chapter including reaction rate, collision theory, activation energy, heat of reaction, potential energy diagrams, reaction mechanisms, rate equations and orders and the factors affecting reaction rate (concentration, temperature, surface area, and catalyst).

It was piloted to 251 high school students who had already learned reaction rate concept, from different schools at 11th grade. Reliability coefficient of the test was found as 0,78.

RRCT was implemented to both groups as pre-test to control students' previous knowledge and post-test to measure students' conceptual understanding in the context of reaction rate.

Science Process Skill Test (SPST)
SPST, which was developed by Okey, Wise and Burns (1982), is composed of 36 multiple choice questions measuring five skills: identifying variables, operationally defining variables, identifying appropriate hypotheses, interpreting data and designing experiments. It was adapted into Turkish by Geban, Aşkar and Özkan (1992). The reliability of the test was found to be 0,85.

Science process skills contribute to students' achievement in education (Blosser, 1975). Brotherton and Preece (1995) stated that there is a close link between cognitive development and science process skills. Most of science misconceptions among secondary school students could be related to the lack of formal reasoning patterns such as the isolation and control of variables, probabilistic thinking, and the schema of proportion.

Science process skills cannot be separated from the conceptual understanding being involved in learning and applying science. Science process skills are means for understanding science and also major goal of science education. Science learning must engage students in activities which invite higher cognitive stage (Harlen, 1999). Therefore, it is necessary to control students' science process skills while investigating improvement in their RRCT scores. For this reason, SPST was administered to both groups before instruction in order to control its impact on students' understanding of reaction rate.

Interviews

Semi-structured interviews were conducted with 12 students from both groups and two schools to get deep information related to students' understanding of reaction rate. The researchers selected the interviewees depending on the students' post-RRCT results as low, medium and high achievers. Correspondingly, two low, two medium and two high achievers were chosen from each group. Interview questions were based on students' answers to RRCT. They were conducted individually for about 20 minutes.

Procedure

This study took 6 weeks of 2008-2009 fall semester in Ankara, capital city of Turkey. Before instruction, RRCT and SPST were implemented to both groups. In experimental group, Treatment Verification Checklist, developed by the researchers, was applied by one of the researchers and a PhD student majored in chemistry education to decide if cooperative learning method was implemented as intended. They observed the groups once a week and filled the checklist. At least 75% of the items were marked as "usually" and "yes" by two observers. The checklist indicated that many of expected characteristics of cooperative learning were satisfied such as, physical arrangement of the classroom (to permit face to face interaction); informing students about characteristics of cooperative learning, social skills expected from them and aim of group activities; heterogeneous groups; individual quizzes; rewarding successful group; involving all members in the activity and enough guidance and feedback by the teacher. The checklist was not used in statistical analysis. During the instruction, students worked on worksheets as a group cooperatively to reach instructional outcomes.

In traditionally instructed classroom, teacher taught reaction rate through discussion and lecturing. The teacher described and defined the concepts, wrote related chemical equations and key words on the board, students took notes, and after teacher's explanations, the concepts were discussed through teacher-directed questions. Teacher sometimes used analogies and daily life examples to make some points more concrete since reaction rate is an abstract topic of chemistry. The instructions in control groups were observed to ensure that similar contents with experimental group were covered and similar teaching strategies in control groups of both schools were used by two teachers. The observers reflected that most of the students were passive listeners and note takers and student-student interaction was not allowed. Similar questions and content were covered in the control group as in cooperative learning class. On the other hand, teacher didn't consider students' misconceptions or their existing knowledge during instruction. He was the center of the classroom and the students listened to him quietly during the lesson.

Analysis

Previous to treatment, independent-samples t-test was conducted by using Statistical Package for Social Sciences to determine whether there was a significant mean difference between experimental group and control group in terms of SPST and pre-RRCT scores. One-way ANCOVA was used for the analysis of post-RRCT scores to reveal the effect of cooperative learning on students' understanding of reaction rate. Students' scores on SPST were assigned as covariate.

FINDINGS

The results of analysis of post-RRCT scores indicated that there was no significant mean difference between the groups with respect to previous reaction rate concept understanding measured by pre-RRCT, $t(108) = -0.272$, $p > 0.05$. On the other hand, there was a significant mean difference between them with respect to science process skills measured by SPST, $t(108) = 2.59$, $p < 0.05$. As a result, SPST was assigned as covariate in the analysis of post-RRCT scores.

After meeting the assumptions, one-way ANCOVA was conducted, in which SPST scores was assigned as covariate. Descriptive statistics for pre-RRCT, SPST and post-RRCT scores of the students of both groups is given in Table 1.

Table 1. Descriptive Statistics for Pre-RRCT, SPST and post-RRCT

Group	N	Pre-RRCT		SPST		Post-RRCT	
		Mean	SD	Mean	SD	Mean	SD
EG*	56	8.66	3.58	23.10	3.84	18.82	3.28
CG**	54	8.83	3.03	21.20	3.83	15.87	3.46

* Experimental Group
** Control Group

The results for analysis of post-RRCT scores indicated that there was a significant mean difference between the groups in terms of students' understanding of reaction rate concept. In other words, cooperative learning caused better results in terms of coping with students' misconceptions about reaction rate compared to the traditional instruction. Table 2 presents ANCOVA results.

Table 2. Results of One-way ANCOVA

Source	df	F	p	Partial □^{2}
SPST	1	28.23	0.00	0.20
GROUP	1	13.59	0.00	0.11

Partial □^{2} of 0.11 means that there is almost a large relationship between treatment and dependent variable, referring that the magnitude of the difference among groups was nearly large (Kittler, Menard & Phillips, 2007). This means that, 11 % of variance on dependent variable was attributed to treatment. In the same way, partial □^{2} of 0.20 suggests a strong relationship between treatment and covariate. That is, 20 % of variance, which is a large value, on dependent variable was explained by science process skills of the students. Therefore, the effect of science process skills of students on their understanding in reaction rate concept cannot be underestimated. It is necessary to consider students' science process skills while investigating their conceptions or achievements in science.

To sum up, cooperative learning led to better results in terms of dealing with students' misconceptions about reaction rate compared to the traditional instruction.

Interview results

Six students from experimental group and six students from control group were selected depending on their scores of post-RRCT for the interviews. Some of the interviews were discussed here because of the page limitations.

Students' ideas about reaction rate

Although most of the students knew that rate of a reaction is calculated by measuring amount of substance consumed or produced per unit time they still had some misconceptions concerning what reaction rate is. Students in both experimental and control group did not have an accurate definition of reaction rate in their minds. Following misconception was detected in students of control group: *forward reaction rate* + *reverse reaction rate* = ΔH. Furthermore, some students had the misconception that r*eaction rate is the time necessary for a reaction to be completed* which was also identified by Kousathana and Tsaparlis, (2002); Nakiboğlu, et al., (2002); İcik (2003) and Çakmakçı (2005).

Change of Reaction Rate with Time

The interviews showed that most of the experimental group students understood how rate of reaction changes with time depending on the concentrations of reactants and they could be able to interpret what they knew on the related graph. On the other hand, control group had great difficulty in understanding change of rate with time and they had also problems with interpretations of related graph. They confused the rate of one-way reaction with the rate of equilibrium reactions during the reaction proceeds. Some students had the misconception that *the rate of the reaction increases at the beginning of the reaction; when reactants are consumed, the reaction rate drops, and at the end of the reaction, the rate becomes zero*, which was also found out by Çakmakçı (2005). In addition, some of them stated that *the rate of the reaction increases with time because the amount of products increases* as also supported by the study of Garnett et al., (1995) and Çakmakçı (2005). Similarly, some students from control group had the following misconception: *rate of a reaction is zero when it is at equilibrium.*

Zero-order reactions

The dialogues related to zero-order reactions indicated that students in experimental group had better understanding of zero-order reactions than the students in control group did. During the interview, a student from control group claimed that *rate of a zero-order reaction increases with time if the "kinds" of products increase*. Another student claimed that *if the reactants of a zero-order reaction were in gas phase, they would be written in the rate equation*. She also had the misconception that *if a gaseous reaction is heated, the rate of the reaction will increase, however, if reactants which are in solid phase are heated, the reaction rate will remain constant during the reaction.* Another misconception revealed by this interview was *rate constant (k) depends on temperature, concentration, and volume of the reactants.*

Effect of Surface Area on Reaction Rate

The interviews related to the effect of surface area on reaction rate showed that students in experimental group had better understanding. They comprehended that increasing surface area increases the number of collisions so the reaction rate increases by interpreting on the visual representations of the reaction vessels. Conversely, control group students had some misconceptions. For example, some students stated that *powdered sugar melts faster than the cube one in tea.* They confused melting with dissolving. They also compared this physical event with a chemical reaction to find out the effect of surface area on reaction rate. A student had the misconception that *crumbled substances move and so react faster than a big piece of a substance.* As a result, students in control group failed to reason their answers.

Effect of Concentration on Reaction Rate

Students in experimental group could interpret a curve related to the effect of concentration on reaction rate. They could conclude that the reaction in which the biggest amount of product formed per unit time is the fastest one. On the other hand, control group students had great problems with interpreting the curve. Most of them deduced that *faster reaction produces more products.* When they were asked the effect of concentration on reaction rate, they could easily answer the question. However, they could not make interpretations on a curve by using this information.

Effect of Temperature on Reaction Rate
Most of the students in experimental group could make correct interpretations on a curve which is related to the effect of temperature on reaction rate. They also could reason their answers. However, a student in experimental group had the misconception that *the higher the temperature is, the more the amount of products formed is*, which was also revealed by the study of Kousathana and Tsaparlis, (2002). On the other hand, experimental group students could reason their answers better than control group students could.

Effect of Catalyst on Reaction Rate
The interviews indicated that students in both groups understood the effect of catalyst on reaction rate. They could use their information to interpret the curve related to the effect of the catalyst on reaction rate. However, a misconception was detected in control group, *catalyst gives energy to the reaction and so increases the activation energy and the rate of the reaction* as supported by Çakmakçı (2005). Another misconception was that *catalyst increases the average speed of molecules* as also identified by Kıngır and Geban, (2006).

DISCUSSION AND CONCLUSION

The main purpose of the present study was to investigate the effectiveness of cooperative learning on 11th grade students' understanding of reaction rate concept. According to the results, cooperative learning resulted in significantly better acquisition of knowledge related to reaction rate and elimination of misconceptions than the traditional instruction. Effectiveness of cooperative learning was also supported by other studies in the literature (e.g. Felder, 1996; Barbosa, J´ofili & Watts,2004; Bilgin & Geban, 2006; Doymuş, 2007; Acar & Tarhan, 2008). In addition, post-RRCT results and the interviews indicated that experimental group students performed better in RRCT and they could provide better reasoning for their answers. However, some of the misconceptions could not be removed in both groups after the instruction. The most frequent and persistent misconceptions, revealed by Reaction Rate Concept Test and the interviews, in consistent with the previous studies (Haim, 1989; Garnett et al., 1995; Nakiboğlu et al., 2002; İcik, 2003; Çakmakçı, 2005; Balcı, 2006; Kıngır & Geban, 2006) are as follows:

- Reaction rate is the amount of substance turning into products per unit time at constant temperature and concentration.
- Students overgeneralized that rate of reactions always decreases as the reaction proceeds without considering the order of the reaction.
- Catalyst increases reaction rate without changing mechanism.

In addition to these, interviews revealed some new misconceptions which are given below:
- Forward reaction rate + reverse reaction rate = ΔH
- Rate of a reaction is zero when it is at equilibrium.
- Rate of a zero-order reaction increases with time if the "kinds" of products increase.
- If the reactant of a zero-order reaction was in gas phase, it would be written in the rate equation.
- If a gaseous reaction is heated, the rate of the reaction will increase, however, if reactants which are in solid phase are heated, the reaction rate will remain constant during the reaction.
- Rate constant (k) depends on temperature, concentration, and volume of the reactants.
- Crumbled substances move and so react faster than a big piece of a substance.
- Particles in lower volume have greater speed than the ones in higher volume.

These results supported the idea that misconceptions are persistent even after the instruction different from traditional way (Novak, 1988). If the teacher does not cope with them, they will distort students' further learning.

In the present study, science process skills of the students explained a significant portion of their conceptual understanding in reaction rate. Essentially, science process skills accounted for 20 % of variance on dependent variable. Therefore, effect of science process skills of students on their conceptions of reaction rate cannot be ignored. That is to say, science process skills of participants should always be considered while investigating their conceptions or achievements in science.

To sum up, contributing to progress of science learning is a sore process. Student-centered methods which provide students with construction of their own knowledge require more efforts than teacher-centered methods. However, teaching strategies where the students are actively involved in their learning process like cooperative learning promote meaningful learning.

HOW TO SET A GOOD EXAMPLE TO PUPILS? TEACHERS' PURPOSE IN LIFE AND BEHAVIORAL INTENTIONS TO PROTECT NATURE

Gregor Torkar

EGEA, Institution for nature,
Tacenska cesta 135a, 1133 Ljubljana, Slovenia

gregor.torkar@guest.arnes.si

ABSTRACT

Educational programs can provide more than just information; they can enrich a learner's values, build skills and offer positive environment for practising nature-friendly behaviours. Our main interest was studying teachers' behaviour towards nature protection. Teachers in primary schools often influence pupils' attitudes towards science subjects and are also role models in pupils' formation of environmental attitudes. We investigated how teachers' behavioural intentions are influenced by the degree of their purpose in life and by different teachers' professions. A study was conducted on a sample of 341 Slovenian teachers. Behavioural intention questionnaires and Purpose in Life test were used to measure the dependent variables. We found a teacher's purpose in life has a positive impact on behavioural intentions to take public and private actions to protect nature. There were also some indications that more environmentally educated teachers (biology and science teachers) express higher preparedness for nature-friendly behaviours, but not in all cases the differences were statistically significant. From the results we can conclude that in addition to teacher training, personal traits are also important for future development in environmental education. Therefore, some improvements in teacher's development are suggested that would lead to more effective environmental education.

Keywords: teacher, nature protection, behavioural intentions, purpose in life test, professional development, personal development

INTRODUCTION

Environmental Education

Humans have been learning about the natural world and teaching each other what they learn for thousands of years. The depictions of horses, lions, rhinoceroses, and other animals at Chauvet-Pont-d'Arc cave in France and other Paleolithic artwork indicate an intimate knowledge of the natural world. The human ability to learn about the natural world and apply what is learned has been a key factor in human dominance as a species (Hayes 2008). Our present-day view of the nature and learning is much more complex and the level of influence on the natural environment has long outgrown cave paintings and reached global dimensions. Among the international scientific community there is a widespread consensus that global warming is happening and that its causes are also anthropogenic (Selby 2007). As global economies and human population grow and as development expands, social conflict over natural resources will inevitably increase in the coming years (Manfredo 2008). The majority of the world's population is being urged to accept the modern idea that "everything that can be made must be made, and then sold" and that this view of everyday reality is being "unshakably structured by the omnipotence of technoscientific truth and the laws of the market" (Berthoud 1992, p. 71).

The need for improved education about the environment grows as conflicts over natural resources increase (Jacobson et al. 2006). The concern for environment is becoming a more and more significant issue nationally and internationally. The principal goal of environmental education is to raise environmental awareness and to improve environmental knowledge among learners. But is this enough? Knowing about something does not necessarily mean caring or doing anything about it. Programs that simply provide information often do not lead to hoped changes, except where the lack of information is a significant barrier to environmental behaviour (Schultz 2002). The good news is that educational programs can provide more than just information; they can enrich learner's values, build skills and offer a positive environment for practising new nature-friendly behaviours (Leal Filho 1995, Schultz 2002).

Kates et al. (2001) argue that many environmental problems do not lend themselves to analysis by the conventional, rational approach of defining the problem, collecting data, analyzing data, and making decision based on the results. Environmental education not only criticizes conventional science itself, but current science education practice as well (Korfiatis 2005, p. 236). This criticism focuses on those educational approaches which fail to acknowledge that no science teaching can avoid communicating messages about how we humans look upon and treat nature (Korfiatis et al. 2004) and that these messages influence attitudes towards nature (Brackney and McAndrew 2001). Those educational approaches promote teaching science as value-free knowledge, without seeking deeper understanding of the destructive and hegemonic role of modern science, as well as of its conceptual, social, cultural and moral background (Ashley 2000, Hart 2002). On the contrary, environmental education strongly supports the position that knowledge is socially constructed, that there are cognitive, economic, moral and philosophical aspects to be considered and that there are no certainties in theory or in practice (Selby 2007). It also seeks to develop critical skills needed for informed personal decisions and to empower people to take action on environmental issues (Dillon and Scott 2002, Hart 2002).

Envrionmental Behaviour and Teacher's Role

Chawla and Flanders Cushing (2007) explained that the background of action is much more complex than knowledge alone and they raised an important question: "What kinds of actions most effectively address environmental problems?" They emphasised that it is not enough for environmental education to promote individual private actions for the environment. Environmental education needs to emphasize the most strategic actions. Stern (2000) distinguishes "private sphere" and "public sphere" environmentalism. Measures of responsible environmental behaviour in environmental education research have typically focused on private actions (turning off unneeded lights, recycling, composting, green purchasing etc.) (Chawla and Flanders Cushing 2007), but is this all education can do? If we wish to solove world's most serious environmental problems, such as climate change, only taking (educating for) private actions without collective public change, built on many-sided and many-levelled approach (education), will not be enough. Chawla and Flanders Cushing (2007: p.438) said: "If environmental educators confine themselves to fostering private sphere environmentalism, they may in fact be leading students astray."

Our main interest was studying teachers' behaviours towards nature protection, because teachers in primary schools influence pupils' attitudes towards science subjects (Lederman 2008) and they are often role models in pupil's formation of environmental attitudes (Chawla 1998, 1999, Chawla and Flanders Cushing 2007). Chawla (1999) finds that environmental teachers are expected to prepare students to be successful citizens as well as leaders who will be able to take affirmative environmental actions. Teacher's personality is obviously one of very important factors that influence pupil's environmental attitudes and behaviours or as Dewey (1997) said: "Example is more potent than precept; and a teacher's best conscious efforts may be more than counteracted by the influence of personal traits which he is unaware of or regards as unimportant." Demirbolat (2006) suggested that a teacher's values are more influenced by factors like personal attributes and the environment in which person grew up, than the programmes that educate teachers. We intend to find out how teachers' different professions influence their behavioural intentions towards nature protection.

We have explored teachers' behavioural intentions and not actual behaviours. Sometimes certain behaviours aren't practiced despite someone's strong will. Behavioural theories, such as the theory of planned behaviour (Ajzen 1991), emphasise the role of behavioural intentions to be the most immediate and important predictor of behaviour. Intentions are explicit decisions to act in a certain way, and they concentrate on a person's motivation towards a goal in terms of direction and intensity (Sheeran 2002). The behaviour should be easily accessible or in other words, it is easier to achieve change if the practical conditions exist to support the behaviour (Ryden et al. 2003). Studying someone's behavioural intentions can give us insights into their preparedness for actual behaviour. Studying intentions instead of actual behaviour helps exclude external barriers to performing desired behaviours. Respondents decide solely on the basis of their own values and attitudes, regardless of whether the actual circumstances permit the realization of behaviour.

Teacher's Purpose in Life

In the article we focused our attention on Viktor Frankl's Logotherapy. He (1987) wrote that every individual has an innate desire to develop a purpose in life, which he termed "will to meaning". He says that a purpose in life is innate for any human being and is a basic human need in the development of a person's spiritual dimension which is composed of values, meanings, freedom and responsibility. This dimension offers to each individual the ability to identify and assess meaning of life decisions in a given time position.

Viktor Frankl (1973) gave a general guide how to find meaning and that requires a certain attitude towards the world. Frankl (1973) wrote: "We must perform a kind of Copernican Revolution, and give the question of the meaning of life an entirely new twist. To wit: "it is life itself that asks questions of man… it is not up to man to question; rather, he should recognize that he is questioned, questioned by life; he has to respond by being responsible; and he can answer to life only by answering for his life." (p. 62) This phenomenological attitude is an openness of mind free from personal interest. It is directed towards the essence of the situation that allows one be reached or even captured by the situation. If the essence of a situation is valuable in itself, is seemingly perfect and cannot be made better than we are left to enjoy, admire and simply experience (Längle 2003). According to Frankl (1987) we can discover the meaning in life by doing a deed (creative work), by experiencing a value (nature, art, music) and by suffering (the stand we take in situation of unavoidable tragedy). The aim of the Logotherapy is enabling a person to experience his or her life freely at the spiritual and emotional levels, to arrive at authentic decisions and to come to a responsible way of dealing with themselves and the world around them (Längle 2003).

Complex way of thinking is necessary not only for teachers and their integration of teaching content. It is crucial to equip students with this complex way of thinking and cooperative learning that will help them face and resolve complex environmental problems. Logotherapy can teach us an important lesson. Frankl (1987) said that logotherapy is neither teaching nor preaching. It is as far removed from logical reasoning as it is from moral exhortation. To put it figuratively, the role played by a teacher is rather that of an eye specialist than of a painter. Frankl (1987) postulated that the life of a responsible human being is oriented to somebody or something (for example: nature, creative work, art) outside him- or her-self. He called this human ability a self-transcendence and saw it as a way of finding personal meaning in life. Previous empirical studies support that human values of self-transcendence have positive impact on attitudes, behavioural intentions and self-reported behaviours toward environmentalism (see Karp 1996, Schultz et al. 2005, Torkar 2009). The role of a teacher is to motivate learners to experience their life freely to arrive at authentic decisions; to come to a responsible way of dealing with the world around them. Frankl clearly considers Logotherapy to be valuable to the quest for wisdom. It is through the creation of this meaning that individual can experience wisdom and understanding.

Based on Frankl's theory, Crumbaugh and Maholick (1964) developed the Purpose in Life (PIL) Test. In the published research about the PIL, having a sense of purpose in life clearly contributes to establishing positive characteristics, strong values, and healthy mental attitudes. The PIL has been used widely in clinical and outpatient contexts in clinical psychology. Studies have proven PIL's effectiveness in determining levels of occupational meaningfulness (Crumbaugh 1968) and lesser degree of purpose among prison inmates (Reker 1977). Studies have shown that those with higher meaning in life suffer less anxiety and have greater self-confidence (Yarnell 1971, Reker 1994), self-acceptance (Crumbaugh and Maholick 1969), work motivation (De Klerk 2001), happiness and life satisfaction (Compton 2000), and social attitudes (Pearson and Sheffield 1975). They also experience greater satisfaction with their lives (Reker and Cousins 1979), have more positive expectations of the future (Reker and Cousins 1979), and enjoy increased emotional stability (Crumbaugh and Maholick 1969). Molasso (2006) found that colleague students who are spending more time with friends, studying, exercising, attending parties and social events, working on campus, an interacting with faculty outside of the classroom have more positive sense of purpose. However, while there is rich research on the PIL, no study on the PIL specifically with environmental education or behaviour issues was identified. Therefore, we focused our attention on a question how a teacher's purpose in life influences his or her behavioural intentions to protect nature.

METHODOLOGY

The study was conducted on a sample of 341 teachers working in Slovenian primary schools (n = 118 kindergarten teachers, n = 118 elementary school teachers, n = 105 biology and science teachers). The sample included 3 males and 338 females. Most were 40 to 45 years old. Although these teachers do not comprise a random sample representative of the Slovenian population, there is no reason to believe that the sample represents any particular bias other than gender. In fact, most educators in Slovenia are female, which was also the case in this sample.

A Behavioural Intention Questionnaire (BIQ) with 9 items and a Likert five-point scale (from 1 = strongly disagree to 5 = strongly agree) was designed for the study. Based on Viktor Frankl's (1959) theory, Crumbaugh and Maholick (1964) developed the Purpose in Life (PIL) test with 20 seven-point scale items to measure the degree of teacher's purpose in life. The range of total scores for PIL test was 20–140.

The BIQ mean score and total PIL test score were calculated. PIL test scores were classified into three groups using K-Means Cluster Analysis. Behavioural intention items were submitted to factor analysis with Varimax rotation and three factors with eigenvalues greater than 1.0 derived. Factors were termed "taking public actions" (3 items, α = .66), "taking private actions" (4 items, α = .62) and "contributing money" (2 items, α = .78) for nature protection (Table 1). These three factors explained 62.3 % of the total variance. In order to examine how a teacher's profession and sense of meaning influenced their behavioural intentions towards nature protection, an analysis of variance test was used to analyze the data. A teacher's profession and the PIL test cluster were defined as independent variables, and the behavioural intention factors as dependent variables. Finally we used Pearson's product moment correlation coefficient for exploring the relationship between behavioural intentions and the PIL test score.

Table 1. Factor analysis (with varimax rotation) for BIQ items

	Factors		
	Taking public actions	Taking private actions	Contributing money
I am prepared to attend a seminar or workshop aimed at deepening the knowledge about nature protection.	,639		
I am prepared to attend activities (work campaign, research...) for nature conservation.	,773		
I am prepared to join an organization which advocates the nature protection.	,804		
I am prepared to support the increase in taxes if the money thus obtained is used for nature conservation.			,867
I would give part of my income if I am convinced that this money will be used for nature conservation.			,873
I am prepared to use more public transport and bicycle, in order to reduce air pollution.		,460	
I am prepared to sign a petition that calls for the protection of nature.		,481	
I am prepared to save electricity.		,849	
I am prepared to recycle paper and other waste in the household.		,812	
Eigenvalues	3,092	1,463	1,052

RESULTS AND DISCUSSION

The mean score for BIQ items was 3.95 (SD = .46). The result indicates that Slovenian teachers were generally quite keen to adopt behaviours that protect nature, but not all suggested behaviours got the same level of support. Teachers were more prepared to take private actions for nature protection (x = 4.26, SD = .45) than to take public actions (*x* = 3.89, SD = .58) or to contribute money (x = 3.45, SD = .89). Chawla and Flanders Cushing (2007) emphasised that it is not enough for environmental education to promote private actions and that environmental education needs to emphasize the most strategic actions. The results are not encouraging, because teachers were considerably less prepared for the public conservational activities. Slovenian Teacher's important role in the classroom (Chawla 1998, 1999, Chawla and Flanders Cushing 2007) would certainly require more community oriented and insightful defenders of nature protection.

A one-way ANOVA was used to test differences between groups of teachers of different professions on their behavioural intentions to protect nature. Teachers' different professions significantly influenced their intentions to take public actions for nature protection ($F_{(2,328)} = 6.846$, $p < .05$) and willingness to contribute money for nature conservation ($F_{(2,309)} = 9.328$, $p < .001$), but there were no significant differences in intentions to take private actions ($F_{(2,334)} = 2.399$, $p > .05$). Tukey post-hoc comparisons of the three groups indicate that that there is a significant difference in preparedness to take public action for nature protection between elementary school teachers (*x* = 3.76, *SD* = .60) and biology teachers (*x* = 4.05, *SD* = .56) in favour of the later, *p* = .001. Elementary school teachers (*x* = 3.20, *SD* = .87) were also less prepared to contribute money for nature protection than biology teachers (*x* = 3.71, *SD* = .82), *p* < .001. Comparisons between other groups were not statistically significant at p < .05. Results show that more environmentally educated teachers (biology and science teachers) express higher preparedness for nature-friendly behaviours, but not in all cases the differences were statistically significant. No statistically significant differences were found between kindergarten and biology teachers, what indicates that also other variables could be important.

A one-way ANOVA was used to test how a degree of purpose in life influences on behavioural intentions to nature protection. The results of the Purpose in Life (PIL) Test (Crumbaugh and Maholick 1964) show some significant influences. Behavioural intentions to take public actions ($F_{(2,337)} = 7.784$, $p < .001$) and private actions ($F_{(2,337)} = 6.626$, $p < .05$) for nature protection were significantly influenced by a teacher's purpose in life. No significant influence was found for the money contribution factor ($F_{(2,337)} = 1.560$, $p > .05$). Teachers that find their life highly meaningful were the most prepared to take public and private actions for nature protection.

Links between BIQ mean score and the PIL test total score were tested by using Pearson correlation coefficient. The correlation between the BIQ mean score and the PIL test total score is statistically significant (Figure 1). Teachers having a higher sense of purpose in life were more prepared for environmental behaviours. The results clearly show that teachers who find their life highly meaningful are the most prepared to take public and private actions for nature protection and consequently have an important impact on science and environmental education, as suggested by Lederman (2008) and Chawla (1999).

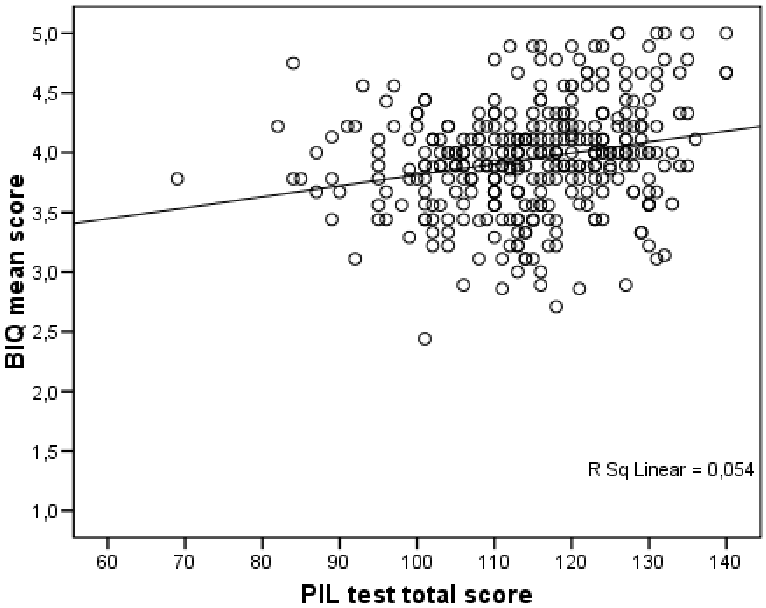

Figure 1. Relationship between the BIQ mean scores and PIL test total score ($r = 0.233$, $p < .001$, $n = 337$).

CONSLUSIONS

In the paper we presented an analysis of teachers' behavioural intentions by the degree of their purpose in life and by different professions of the teachers. Korfiatis et al. (2004) wrote that no science teaching can avoid communicating messages about how we humans look upon and treat nature. We agree with researchers, such as Chawla (1998, 1999), that a teacher can be a very important role model in shaping pupil's or student's attitudes towards nature protection. From the results gathered we can conclude that teacher's purpose in life and profession are important for predicting his or her behavioural intentions to protect nature. Teachers who find their life highly meaningful are the most prepared to take public and private actions for nature protection and consequently have an important impact on science and environmental education. Teachers, whose profession requires a better understanding of environmental issues, show some positive signs for the environmental behaviour, but it is still far from being as important as the purpose in life variable.

In conclusion, today is very difficult to offer pupils or students a relevant knowledge, skills and experience to benefit the lives of tomorrow. Therefore, teachers need constant in-service training to be keept informed about the development of environmental issues. But despite that, teacher's knowledge is often not sufficient to address environmental issues. A major challenge in the science of the last few decades is the recognition that nature is complex (Levin 1999). Science ecology and the field of applied ecology are in a shift from reductionism to a system view of the world, a shift to include humans in the ecosystem (Levin 1999). A single discipline cannot address the complex and changing environmental issues. Partnerships between different disciplines and societies are essential in order to integrate or generate a new knowledge. Teachers should be more open and responsible for cooperation and long-term partnerships. Partnerships should include dialogue among teachers of different scientific disciplines (natural sciences, social sciences and humanities) as well as with local community, NGOs, scientists and other groups of interest in order to generate new knowledge and ideas necessary to address complexity of environmental issues on local, national and global level.

ABSTRACT

Two views of Human-Nature relation can be found: anthropocentrism and ecocentrism. In order to understand how school textbooks refer the human's position in nature we analysed how the axis of analysis "Human as guest *versus* Humans as owners of nature" is present in the three topics of environmental education – *Ecosystems, Pollution* and *Use of Resource* – in textbooks of 14 countries from Europe, Africa and Middle East. A specific grid of analysis, which was constructed in the context of a European Project BIOHEAD CITIZEN was used in this study. Results show that this axis of analysis is present in the majority of textbooks addressing the above three topics but not in the "*Biodiversity*" topic. Textbooks for 12-15 years old pupils were the ones having more occurrences than those for 6-11 or 16-18 years old. The textbooks present mainly an ecocentric position, whereas the aesthetic, ethical and cultural aspects are limited and inadequate, limiting the full perspective of education for sustainable development.

Keywords: *Environmental education, Human-Nature relation, Textbooks.*

INTRODUCTION

The understanding of the Human-Nature relationship affects strongly people's worldviews (Rehmann-Sutter, 2000) and differences in worldviews determine the way people conceptualize the need for addressing solutions of the existing environmental problems. As Esteves (1998) defends it is necessary to develop, in each of us and also in the Humanity, the sense of responsibility and solidarity through the environment.

Two perspectives of Human-Nature relation can be found: anthropocentrism and ecocentrism (Almeida, 2007). The former focuses in the relations between Humans and the Universe (Esteves, 1998) and confers humans' dominance over nature, where they, in the ecosystem, occupy the top of an alimentary chain. The latter aims at the ecosystem itself, where the humans are seen as elements of the biotic community having an attitude of respect for all the elements of that community (Almeida, 2007). It is easy to understand that these questions are not easy to solve but we have to have in mind ethical positions in order to solve the different environmental problems. It is also required a moral, ecological and economic perspective in the relation Human-Nature. This is to say that we need a change of attitudes in order to obtain a better world. In the sense of changing attitudes through the environment that surround us, in the sense of constructing a better world, it is pertinent the intervention of educative actions to make children and young people aware of environmental problems and promote positive attitudes and behaviours.

Textbooks analysis is seen as a major element in the evaluation of how the educational goals (at the legislative level of national programmes) are implemented at the school level where pupils must acquire knowledge, competences and develop appropriate values towards a sustainable environment (ME,1988). These textbooks are used by teachers with a double function: as a national programme (or syllabuses) guideline and as a didactical resource (Carvalho *et al*., 2009). Thus the textbook analysis turns out to be a relevant tool for studying socio-cultural determinants of environmental problems, in particular the school-related ones.

In order to understand how school textbooks refer the human's position in nature we analysed how the axis "Human as guest *versus* Humans as owners of nature" is present in the following topics of environmental education: *Ecosystems*, *Pollution* and *Use of Resource*.

METHODOLOGY

This work was performed by using specific parts of the grid of textbook analysis on the topic "Ecology and Environmental Education" constructed by the European FP6 STREP project BIOHEAD-CITIZEN (CIT2-CT-2004-506015) (Carvalho & Clément, 2007; Caravita *et al*., 2008). For the design of the grids of textbooks analysis, precise subtopics being exemplar of interactions between Science and Society, and challenges in Citizenship were chosen. They were: *Pollution, Use of Resources*, *Ecosystem and Cycles* and *Biodiversity*.

The corpus of this study was composed of 128 textbooks containing the topic *Ecosystems and Cycles*, *Pollution* and the *Use of Resources* in 14 countries involved in the European project FP6 BIOHEAD-CITIZEN CIT2-CT-2004-506015 (Carvalho, 2004): Cyprus, Estonia, Finland, France, Germany, Hungary, Italy, Lebanon, Lithuania, Malta, Morocco, Portugal, Romania and Senegal.

The above three topics were analysed in each country textbooks by the respective project teams by looking specifically to the axis "*Human as guest vs Humans as owners of nature"* in *Pollution*, *Use of Resources* and *Ecosystems and Cycles* (Tracana, 2009). The textbooks analysed were the ones more used in each country, and in some countries they only one textbook was used in schools. We looked for images and textual occurrences by using the grids of analysis. For each indicator we registered the images occurrences that appeared in the textbooks (Tables 1, 2 and 3). The problem of subjective interpretation in this kind of qualitative analyse, was controlled by having two analysts separately applying the grids and cross-checking the findings afterwards.

Table 1: Part of the *Pollution* grid related to *Human as guest* vs *Humans as owners of nature*

Content (Themes, topics)	Indicators	Page number of Images	Figure numer of Images	Occurence s in text
IMPACTS of POLLUTION				
	Impact on humankindkind *(only benefits and risks for humans)*			
	Economic consequences			
	Social *risks*			
	Aesyhetic values			
	Ethic, moral and cultural motivations *(e.g. future generations)*			
	Impact to ecosystem			

Table 2: Part of the *Use of Resources* grid related to *Human as guest* vs *Humans as owners of nature*

Content (Themes, topics)	Indicators	Page number of Images	Figure number of Images	Occurences in text
RESOURCE AVAILABILITY				
	Finite (limited) availability of resources			
	Infinite (unlimited) availability of resources			
	Renewable or non renewable resources, including food			
SUSTAINABILITY				
	Ecological sustainability			
	Social sustainability			
	Economic sustainability			
	Ecological-social-economic sustainability			
EQUITY				
	Resources distribution			
	Differences in distribution			
	Relevant factors for equity of distribution			
	Ecological conditions			
	Cultural conditions (knowledge, technology, education,..)			
	Ethical, moral norms			
	Economic conditions			
	Political decisions			
	International agreements			

Table 3: Part of the *Ecosystems and Cycles* grid related to *Human as guest* vs *Humans as owners of nature*

Content (Themes, topics)	Indicators	Page number of Images	Figure number of Images	Occurences in text
CONSERVATION and MANAGEMENT of NATURE				
	Motivation for Conservation **(Only if explicitly mentioned in the text)**			
	To preserve a source of aesthetic pleasure for humans			
	To prevent exhaustion of natural resources important for economy			
	To prevent ecological dis-equilibrium			
	To respect nature and all living beings			

A qualitative approach was used for textbooks analysis but quantitative analysis was also used wherever possible in order to be able to compare items among countries.

RESULTS AND DISCUSSION

The analysis of the textbooks showed that the axis "Humans as owner's *versus* Humans as guests of nature" appears in three subtopics of environmental education *Pollution, Use of and Ecosystems*, but not in *Biodiversity*. This absence can be due to the fact that this axis in *Biodiversity* is not considered so important. In other studies (Tracana, 2009) it was also found that little importance was given to *Biodiversity* in all textbooks as compared to the topic *Pollution* or the *Use of Resources.* It seems that textbooks refer the problematic of species extension but not in a deep manner. This is a curious aspect because today the media address constantly these problems and the school should also take these matters into account in order to contribute for a better citizenship.

This axis "Humans as owner's *versus* Humans as guests of nature" is present in the majority of textbooks. Those booksfor 12-15 years old pupils are the ones having more occurrences than those for 6-11 or 16-18 years old, in all the subtopics *Pollution*, *Use of Resources* and *Ecosystem and Cycles* as it can observe in Tables 4, 5 and 6.

In Table 4 we observe that the item *"Impact to ecosystems"* is the most referred one, followed by the *"Impact on humankind"*. This occurs, perhaps because they are the ones that have more impact in human life. The *"Aesthetic values"* and "*Ethic, moral and cultural motivations"* have residual presence, which means that the textbooks do not give importance to these issues.

Table 4: Textual occurrences of the *Human as guest* vs *Humans as owners of nature* in the subtopic *Pollution* in 40 textbooks

Textual occurrences	Pupils' age			Total
	6-11	12-15	16-18	
Impact on humankind	21	39	31	91
Economic consequences	4	6	14	24
Social risks	2	14	5	21
Aesythetic values	2	2	5	9
Ethic, moral and cutural motivations	0	7	2	9
Impact to ecosystems	51	72	67	190
Total	80	140	124	325

The aesthetic values are beauty values (Jeronen & Kaikkonen, 2002), and our results showed that they are poorly referred. Not only aesthetic but also ethic and cultural issues were found to be absent in the axis of *Human as guest vs Humans as owners of nature,* indicating that textbooks are not approaching appropriately the sustainability aim. This is a point which should be improved in the textbooks. According to Sachs (1993), to reach environmental sustainability it is necessary to consider simultaneously: *i) social aspects*, with the goal of reduce distance between life pattern of social groups; *ii) economical aspects*, made possible by an efficient allocation and management of the resources, much more under macros social criteria than micros social entrepreneurs and by regular flow of public and private investment; *iii) ecological aspects*, involving measures to reduce the resources consumption, and residual production, measures to intensify research, to introduce clean and resource saving technologies, and to define rules that allow an appropriated environmental protection; *iv) spatial aspects*, looking into a more balanced configuration of the rural-urban issue; *v) cultural aspects*, in order to get endogenous conceptions of involvement that respect the peculiarity of each ecosystem, each culture and each place.

Renewable or non renewable resources (Table 5) are more referred (42 occurrences) in the textbooks than the other items. This demonstrate that the textbooks are preoccupied to pass the information to pupils that the natural resources are not infinite, and they should be economically and rationally used. Torres (2007) claims that is important understanding that humanity must not dominate nature but interact with it. This is to say that nature should be used to attend not only the needs of this generation but also the subsequent ones. This leads to the importance of environmental education for the sustainable development.

Table 5: Textual occurrences of the *Human as guest* vs *Humans as owners of nature* in the subtopic *<u>Use of Resources</u>* in 31 textbooks

Textual occurrences	Pupils' age			Total
	6-11	12-15	16-18	
Resources, availability				
Finite (limited) availability of resources	3	15	9	27
Infinite (unlimited) availability of resources	3	2	5	10
Renewable or non renewable resources, including food	10	17	15	42
Sustainability				
Ecological sustainability	1	18	1	20
Social sustainability	–	3	–	3
Economic sustainability	–	5	2	7
Ecological-social-economic sustainability	1	9	7	17
Equity				
Resources distribution	–	–	–	–
Differences in distribution	14	11	1	26
Relevant factors for distribution equity	–	–	–	–
Ecological conditions	–	3	3	6
Cultural conditions	–	3	2	5
Ethical, moral norms	–	3	–	3
Economic conditions	1	3	13	17
Political decisions	–	3	–	3
International agreements	12	1	–	13
Total	45	96	58	199

For the analysis of humans in nature position as far as *resource availability* and *sustainability* are concerned, we observed that the textbooks transmit mainly an ecocentric position. However when looking at *equity*, the economic conditions is the most referred item, suggesting the societal importance given to economy in the goods distribution.

Table 6: Textual occurrences of the *Human as guest vs Humans as owners of nature* in the subtopic *<u>Ecosystems</u>* in 28 textbooks

Textual occurrences	Pupils' age			Total
	6-11	12-15	16-18	
To preserve a source of aesthetic pleasure for humans	4	7	2	13
To prevent exhaustion of natural resources important for economy	1	12	3	16
To prevent ecological dis-equilibrium	2	21	2	25
To respect nature and all living beings	35	9	3	47
Total	42	49	10	101

In the case of the subtopic *Ecosystems* we observed that the respect of nature and living beings was the item more referred. Once again the aesthetic aspect is the less considered.

These results show that textbooks in this analysis consider men as invited and not as owner of nature.

In conclusion, we can say that the textbooks from 14l countries, tend to defend the ecocentric perspective, where humans are seen as guest of nature and not its owner. Results also show that, in respect to this axis – “Humans as owner’s vs Humans as guests of nature” – the aesthetic, ethical and cultural aspects are inadequate, limiting the education for sustainable development. To reach the sustainability, it is necessary to look all together social, economic, ecological, spatial and cultural aspects (Sachs, 2001; 2004).

Further studies are going on to find out whether textbooks from groups of countries (Western or Eastern European countries and non European countries – African and Middle East countries) show specific tendencies in the way environmental education deals with the issue “Humans as owner’s *vs* Humans as guests of nature”.

ACKNOWLEDGEMENTS

ABSTRACT

Family science and technology education is an innovative teaching and learning strategy for children and adults. Family science and technology education is defined as expanding science and technology knowledge and skills from the school into the homes of students. Innovative educational goals of this strategy are evidently lifelong education of adults, but also strong motivation for children for science and technology education. This strategy induces a set of special educational methods, techniques and instruments. Hands-on experiments and activities based on simple equipment that can be found in most homes play a very important role. From the pedagogical constructivist point of view it is important to select and shape these educational activities to be suitable for families. The appropriate educational contents are daily lives. The combination of human body phenomena and hands-on activities results in motivation for children and adults. Family science and technology education also helps to identify and to develop those students gifted in science and technology. This presented research of the family science and technology education opens a new dimension of science and technology curriculum opportunities, teaching and learning strategies, and it demands development of special curricular materials.

Keywords: *Family science and technology education, hands-on experiments, lifelong education, motivation in science and technology education, daily and safe living.*

1. INTRODUCTION

Science and technology (S&T) education is becoming lifelong education. The reason is the rapidly growing number of new applications and the expanding knowledge in S&T. The fact that S&T knowledge and skills gained in school do not satisfy the necessities of life anymore could result in negative attitudes towards S&T. Many adults are gradually losing touch with current S&T knowledge and skills, and sometimes do not understand how new appliances work, which is why they prefer not use them.

Parents and grandparents are often unable to help students with homework, because they do not understand the educational contents. This negative attitude might be transferred from parents and grandparents to their children, which can cause lack of motivation in the students to study S&T. Pedagogical research should focus on the problem how to reverse this negative trend. Science teachers are looking for motivational teaching techniques which would help to eliminate a negative attitude toward S&T (Trna & Trnová, 2006a). Combination of these cognitive motivational teaching techniques can strongly increase motivation of students.

The cognitive motivation of students has a positive advantage, but using just this type of motivation is not enough. It is not possible to ignore social and achivement motivation that are developed in the social and family environment (Bransdorf, 2000). Research into social and achivement motivation of students uncovered the significant influence of family (White, 2007). Students themselves indicate their families and especially parents as the most important factors effecting their decisions. Foskett and Hesketh (Foskett & Hesketh, 1997) found that parents are the main stimulus in the process of students' continued educational development. According to Anderson (Anderson, 2004) parents are not only the most often sought out consultants for students, but they are also regarded as the most effective source of advice and information. Sociologist Matějů (Matějů, 2005) indicates that the influence of family in the Czech Republic on the students choice of profession and on career attainments is the most extreme in Europe. The student's family is the key motivational factor, especially during the primary school age. A family's positive attitude toward S&T can affect the student's inclination toward S&T education. This student results in S&T can be appreciated by the family. Such parents might buy S&T toys and kits, take science trips, enrol student in informal S&T activities, etc.

Our research and experience brought us to develop an innovative educational strategy called Family S&T Education (FS&TE). This type of educational strategy is implemented by the transfer of knowledge and skills from the school setting to families. Students who do FS&TE at home have the potential to inspire their siblings, parents and grandparents. We believe that FS&TE is an efficient educational approach, which nevertheless requires several conditions to be met. FS&TE could become a significant and effective part of parents' and grandparents' lifelong education. As it is a by-product of formal school education, it does not demand any additional financial costs. FS&TE can also help members of the older generation to acclimate to new products and information that they might otherwise not understand.

FS&TE could help in school education and also in improvement of student's giftedness for S&T. The influence of family and school on development of student's giftedness is widely recognized. Socio-culturally oriented models of giftedness are based on the assumption that giftedness can be realized only in the appropriate interaction between personal and social factors. According to the best-known model: Tannenbaum´s model (Tannenbaum, 1983), the family, together with peers and school, determines the development of student's giftedness. FS&TE is entirely consistent with Tannenbaum´s findings about the family's influence on the motivation of gifted students. The interaction of two very important factors, family and school, can be a very strong motivational stimulus for the development of a student's giftedness.

We discovered a relatively strong link between school science education and FS&TE. A family can investigate the use of FS&TE or encourage the adoption of this by the school to further develop a student's giftedness. FS&TE can be one of the environmental factors mentioned by Gagné (Gagné, 1991) which can significantly influence the development of giftedness. In accordance with his findings (Gagné, 1991) we can say that the family is the key factor, especially during the primary school age. If a gifted student is surrounded with a family who has a positive attitude toward S&T, this environment will affect the student's inclination toward S&T education. The family support in the form of school performance awards and extracurricular activities may cause that a latent giftedness can be manifested (Karnes & Shwedel, 1982). A student may have potential to demonstrate latent giftedness in the future, but opportunities must be available to manifest this giftedness. FS&TE could be an appropriate opportunity.

FS&TE requires interesting educational contents based on using relevant knowledge and skills from a student's everyday family life. Our pilot study shows the existence of such suitable educational contents for FS&TE, which will be described bellow.

2. RESEARCH AND RESULTS

The appropriate contents used in FS&TE are from our daily lives. These contents include (Trna & Trnová, 2008):

- The human organism: Students deal with the parameters of the human body which can be expressed by means of quantities, units and laws. Also external conditions are very important for the preservation of vital functions of the human organism including health.
- Home, entertainment, sports etc: Students can be motivated by explanation of the usual subjects and phenomena from everyday life such as heat and light sources, means of transport, audiovisual techniques, chemical agents, domestic plants and animals etc. Information about the economical and ecological aspects in everyday living is growing more and more important.
- Safety risks: Protection against negative extraneous influences on the human organism and information on safe behaviour in transport, at work etc.

The human organism is a very interesting object for students and adults. FS&TE involving new medical information can help in the prevention and diagnosis of certain diseases or risks. The important theme is life protection against dangerous influences, which include the fast change of speed, effects of forces, temperature fluctuations, radiation etc. Another important advantage of teaching and learning about the human organism is that teaching aids are not needed because everyone has a body.

The combination of appropriate contents and hands-on activities results in motivation for students and adults. Human body experimenting and measuring are good motivation for students and adults as well. Many human body parameters such as temperature, weight, blood pressure, body mass index, etc. can be measured by students and adults using simple instruments in their homes. Prevention of at-risk factors is based on these human body measurements and potential health risks can be diagnosed with the assistance of these simple hand-on activities.

We undertook the research of educational efficiency of these activities in FS&TE. To prove the effectiveness of this educational strategy for students of different ages, we conducted research in a primary school and then in a lower secondary school. We used the educational contents of human body measurement.

2.1 Flat foot

We used the measurement of flat feet for our research of students in primary school (Trna & Trnová, 2006b). The research of the effectiveness of FS&TE was carried out twice (in 2006 and 2009). One hundred students in the fourth grade in primary science lessons were taught how to measure flat feet.

Students' knowledge background:
The foot structure is very important for various movement conditions of the body. The most known disorder is flat feet caused by fallen arches. Inappropriate footwear is a large contribution to this disorder. That's why the length and width of the foot is important when buying the correct shoes.

Students' hands-on activity:
Paint the sole of the foot with water (oil, ink etc.) and step on suction paper. Use a ruler to measure the widest (w_1) and narrowest part (w_2) of the footprint (Figure 1). Calculate $I = w_2 / w_1$. Evaluate results using the Table 1.

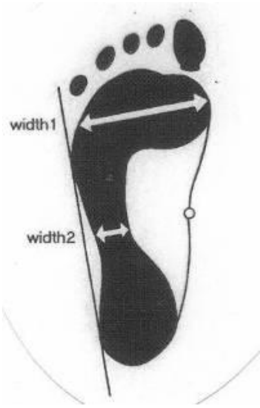

Figure 1. Flat foot

Table 1. Flat foot

$I = w_2 / w_1$	
normal foot	I = less 0, 45
start to be flat	I= 0, 45
flat foot	I= more 0, 45

A questionnaire was distributed to the parents of students after two weeks. Parents were asked to answer four questions concerning the measuring of flat feet. The questions, the percentage of positive answers and the number of questionnaires received back is in Table 2.

Table 2. Flat foot - research results

	Questions for parents	Percentage of answer: YES (2006):	Percentage of answer: YES (2009):	Number of received questionnaires (2006/2009):
1	Do you know a simple method of measuring flat feet?	68	65	75/80
2	Did you receive this method from your children?	60	62	75/80
3	Have you measured your foot using this method?	24	30	75/80
4	Have you found latent flat feet in your family?	4	5	75/80

The research results verify the effectiveness of FS&TE in the primary school science by the use of the combination of hands-on activities and human body measurement.

2.2 Obesity

Our next research concerning the effectiveness of FS&TE was based on the measuring of obesity and it was realized in 2008. One hundred students of the eighth grade in lower secondary science lessons were involved. They were taught how to measure obesity.
Students' knowledge background:

Body weight is defined as an essential parameter that helps us to find out the state of health and even predict health complications in the future. The often used parameter for body weight assessing is body mass index (BMI). The latest investigations verify the importance of the distribution of fat (types of obesity). Fat distribution is possible to find by means of waist and hip circumference which is more predictive of cardio respiratory risks than BMI. The WHR index is the ratio of these two parameters. Only indication of waist circumference is an approximate indicator of the health risks associated with obesity.

Students' hands-on activity:
Use a measuring-tape to measure your waist circumference and hip circumference. Calculate WHR = waist circumference/hip circumference. Evaluate results using the Table 3 and Table 4.

Table 3. Obesity - waist circumference

	Low risk	High risk
Man - waist circumference	> 94 cm	> 102 cm
Woman - waist circumference	> 80 cm	> 88 cm

Table 4. Obesity - WHR

WHR = waist circumference / hip circumference	Types of fat distribution / health risk	boy / man	girl / woman
	Rather peripheral / no risk	up to 0,85	up to 0,75
	Balanced / no risk	0,85 – 0,90	0,75 – 0,80
	Rather central / low risk	0,90 – 0,95	0,80 – 0,85
	Central / high risk	above 0,95	above 0,85

A questionnaire was distributed to their parents after two weeks. Parents were asked to answer questions concerning the obesity measuring. The questions, the percentage of positive answers and the number of questionnaires received back are in Table 5 and Table 6:

Table 5. Obesity (waist circumference) - research results

	Questions for parents	Percentage of answer: YES (2008):	Number of received questionnaires (2008):
1	Do you know a simple method of measuring risk of obesity using indication of waist circumference?	60	84
2	Did you receive a method of measuring risk of obesity using indication of waist circumference from your children?	43	84
3	Have you measured your risk of obesity using this method?	71	84
4	Have you found latent risk of obesity in your family?	22	84

Table 6. Obesity (WHR) - research results

	Questions for parents	Percentage of answer: YES (2008):	Number of received questionnaires (2008):
1	Do you know a simple method of measuring obesity using WHR?	50	84
2	Did you receive a method of measuring obesity using WHR from your children?	43	84
3	Have you measured your WHR using this method?	22	84
4	Have you found latent obesity in your family?	12	84

The results of our second research verify the effectiveness of FSE also in the lower secondary science by the use of a combination of hands-on activities and human body measuring.

3. CONCLUSIONS AND DISCUSSION

The research results verify the educational and motivational effectiveness of FS&TE in the primary school and lower secondary school S&T by the use of the hands-on activities with the human body measurement. FS&TE might hold also another essential function. It can help in the diagnosis and development of gifted students in S&T. According to today's parental demands, school should provide diagnosis of a student's giftedness and carry out further development (Kanevsky, 1992). Professional orientation and student's progress have a comparable value to desirable development concerning his or her future life.

Within the FS&TE strategy, the student's family is able to find out and/or verify the school's recommendation for their child's area of giftedness. As a part of the whole range of other S&T teachers' professional training techniques, the FS&TE strategy is regarded as inseparable from S&T teachers in-service training. It requires understanding the interaction between students and their family background.

FS&TE has a great potential to become an essential strategy for adult lifelong education as well as a motivational technique for gifted and non-gifted students. The interactions between students and their family background include more factors and they are very sensitive. That is why, it requires more detailled additional research and eventual inclusion into pre-service and notably in-service teacher training.

ACKNOWLEDGEMENTS

The study initiated within the project „Special Needs of Pupils in Context with Framework Educational Program for Primary Education"(MSM0021622443).

ABSTRACT

In this research, it was aimed to determine how frequently the alternative measurement and assessment techniques, emphasized by science and technology curriculum, are used in the textbooks and student workbooks, taught in 2008-2009 session, in science and technology course at 6th grade. Within the scope of the research, it was determined how the traditional and alternative measurement and assessment techniques mentioned in science and technology curriculum are used in the books concerned. Moreover, in order to determine the problems teachers are confronted with while using these techniques and to offer proposals of solution for these matters, opinions of 300 science teachers working in various cities were obtained via e- mail. Also, a number of 50 science teachers working in Ankara and Aksaray were interviewed. This study showed that teachers find using alternative measurement and assessment techniques in textbooks and workbooks positive but they do not feel themselves sufficient concerning alternative measurement and assessment techniques. On the other hand, when the negative views are considered, it was observed that teachers stated negative factors as crowdedness of classes, consumption of paper, photocopy and printed documents and insufficiency of time.

INTRODUCTION

Especially together with the development of science and technology, there have been some changes in Science Education Curriculum. The main objective for these changes were enabling students to think creatively, to inquire about events taking place, to think critically and the most important of all is to teach individuals how to be productive. (Balım, Kesercioğlu, İnel, & Evrekli, 2009). These progresses and inventions in Science Education contribute much to the development of a country and constitute a basis for scientific and technologic improvements (Özmen, 2004). In this context, in many countries, Science Education Curriculum was reviewed and reorganized after the consideration of constructivist approach. Constructivism emphasizes the construction of new knowledge by the learner, as well as a focus on active learner-centered experiences (Young and Maxwell, 2007).

Constructivism theory, influenced by the work of Piaget and Vygotsky (Woo & Reeves, 2007), encourages learners to build their own body of knowledge based on individual experience and to apply this knowledge directly to their environment. In constructivism, the individual is at the center of the social process, with the focus on learning rather than on teaching (Ali, Hodson-Carlton, & Ryan 2004). Constructivist approach is defined as individual's correlation of prior knowledge with the knowledge obtained by the interaction between the events and objects existing in his surrounding and constructing it as new knowledge. Constructivist approach is mainly based on Piaget's mental psychology, Ausubel's receptive learning, Bruner's inquiry, Posner and his friends' conceptual change and Johnson and Johnson's social interaction theories(Hand, Treagust, and Vance, K. 1997). Constructivism espouses students are to: be active in the learning environment; develop social and interpersonal skills; enjoy learning; have an understanding of the content being taught; and learn to think in an efficient manner (Kelsey, 2007; Low, 2007).

Irzik (2001), Matthews (2002) and Roscoe (2004) stated that constructivism has vital importance in Science Education since it has an innovative and powerful impact in this field. Due to the use of this approach in learning environments, it has led to redefine concepts such as learning, teaching and knowledge (Chen, Burry- Stock, & Rovegno, 2000). Therefore there have also been changes in the use of measurement and assessment techniques. Constructivism emphasizes that it is necessary to offer multiple assessment opportunities to students, where they can display their knowledge, skills and attitudes, in measurement and assessment as well.

Traditional forms of assessment techniques such as multiple choice tests, true-false questions, matching questions, completion questions, short- answer or long answer examinations and question- answer are easy to administer and grade, whereas they focus on factual recall, promote only simple application of knowledge; and some of them have been found to be teacher-biased (Magnan-Lev, 1997). On the other hand, alternative techniques such as student product file (portfolio), concept maps, constructed grid, diagnostic tree, word association, drama, interview, written reports, demonstration, poster, group and/or peer assessment, self-assessment, diary and checklist are student oriented, they promote learning, involvement and motivation and they also allow for consideration of human characteristics such as prior knowledge, culture and language (Porter, 1991).

According to Pierce and O'Malley (1992) alternative assessment reveals students' knowledge and capability in various contexts; it is authentic because it is based on real life situations. It keeps the interaction between students and teachers alive during teaching and learning processes (Enger &Yager, 1998; Howe & Jones, 1998; Ornstein & Thomas, 2004; Thompson, 2001).

Alternative assessment brings to light not only cognitive but also affective and psychomotor abilities of students. Besides evaluating learning products, it is also effective when assessing the process.(Yaman, Karamustafaoğlu, & Karamustafaoğlu, 2005).

Many educators, who want to emphasize the importance of alternative assessment, made serious criticisms about the handicaps of traditionally used paper and pencil tests (Brooks & Brooks, 1993; Howe et al., 1998; Reeves & Okey, 1996; Smith, Ryan, & Kuhs, 1993; Tippins & Dana, 1992).

Constructivism and in parallel with this alternative measurement and assessment techniques have been a prominent research area for the last two decades (Aldridge, Fraser, Taylor, & Chen, 2000; Avci, Unlu, & Yağbasan, 2009; Demircioğlu, Özmen, & Demircioğlu, 2004; Irzik, 2001; Matthews, 2002; Özerbaş, 2007; Nesbit & Adesope, 2006; Roscoe, 2004; Saygın, Atılboz & Salman, 2006; Semerci, 2001; Aydoğdu, 2003; Taylor & Hsueh, 2005; Rust, O'Donovan & Price, 2005; Thome´ , Hovenberg, & Edgren, 2006).

The new primary education curriculum has been prepared in line with the constructive approach by the Republic of Turkey Ministry of National Education in 2004 and was put into practice in every elementary school of Turkey in 2005-2006 session.

Within the scope of 2004 curriculum reform by Board of Education, the curriculum of the elementary school science course was reevaluated on the basis of constructivism and has been implemented since 2005-2006 session, in Turkey. The name of this course has been changed as “Science and Technology” given the increasing emphasis on the aspects of science topics reflected in the daily life and technology and the class hours were determined as 4 hours per week. Also, textbooks, student workbooks and teacher guide books for this course have been developed in line with the philosophy of this curriculum by General Directors of Primary Education.

The change in the name of the course shows that the science class does not compose solely of knowledge and underline the chief role of technology education in the new curriculum. Furthermore, this change enabled the integration of the technology education and the science topics as a part of the elementary school education for the first time.

The perspective of Turkish Science and Technology Curriculum in terms of assessment and the points it stresses are shown in Table 1.

Table 1. Points stressed by Turkish Science and Technology Curriculum in terms of assessment

Less Stressed	More Stressed
Traditional measurement and assessment methods	Alternative measurement and assessment methods
Assessment independent of teaching and learning	Assessment which is a part of teaching and learning
Assessment of knowledge learned easily and by heart	Assessment of significant and deeply-learned knowledge
Assessment of fragmented knowledge independent of each other	Assessment of a connected and well-constructed knowledge network
Assessment of scientific knowledge	Assessment of scientific understanding and scientific logic
Assessment for learning what the student does not know	Assessment with the purpose of learning what the student has understood
Term-end assessment activities	Assessment activities carried on throughout the term
Assessment only by the teacher	A group assessment with the teacher and self-assessment

When Table 1 is examined, a shift in learning and teaching strategies from teacher - centered structure to student-centered domain can be seen explicitly. This shows that new Turkish science and technology curricula stresses alternative measurement and assessment rather than traditional measurement and assessment (MEB, 2005).

In this research, it was aimed to determine how the traditional and alternative measurement and assessment techniques are used in the textbooks and student workbooks for science and technology course at 6th grade. Moreover, the problems which teachers were confronted with while using these techniques were determined.

METHOD

In Turkey, there are several textbooks published for each grade level of a school subject. School textbooks are designed either by Ministry of Education or private publishers for elementary and secondary school education; however, these textbooks are examined in detail by the Board of Education. Books which are not approved by the Board of Education can not be used as a textbook for teaching at schools. Every year, textbooks are handed out freely to elementary and secondary school students by Ministry of Education.

There are 3 different 6th grade science and technology textbooks and workbooks available on the Turkey market for 2009/2010. As it was our purpose to analyze textbooks and workbooks still in use, publishers were contacted and asked about new books/editions for 2009/2010. It was found that 3 different textbooks and workbooks were either updated or explicitly said to be maintained without any change.

At the first part of the study, a qualitative content analysis of the 6th grade science and technology textbooks and student workbooks by The Ministry of Turkish National Education, Pasifik, Tuna publications, published in 2009-2010 were undertaken. In order to enhance the reliability and validity of the data, the analysis was repeated.

At the second part of the study, it was aimed to determine teachers' views about the sufficiency of alternative measurement and assessment techniques used in 6th grade science and technology textbooks and workbooks.

The population of the study consisted of all the science and technology teachers working in Turkey. The questionnaire was sent to 420 science and technology teachers working in in Ankara, Aksaray, Erzurum, Diyarbakır, Yalova and İstanbul provinces via e-mail. However, 310 of them gave a feed back to us and 10 of them were not evaluated due to insufficient information. As a result the sample of the study included 300 science and technology teachers. A questionnaire and a semi constructed interview were used in the research. The questionnaire was administered to 300 teachers via e-mail and in addition to this, semi constructed interviews were made with 50 teachers giving 6th grade science and technology lessons in rural and urban areas of Ankara and Aksaray.

A questionnaire developed by the researchers was used in order to determine the views of science and technology teachers about the sufficiency of alternative measurement and assessment techniques used in textbooks and workbooks. The legibility and validity of the questionnaire was examined by 3 specialists in the field. The questionnaire comprised of two sections. At the first section of the questionnaire, teachers' profiles and their participation status to in-service training about alternative measurement and assessment techniques and at the second section, teachers' views about alternative measurement and assessment techniques used in the textbooks and workbooks existed.

In order to obtain data about the problems teachers confronted while they were using alternative measurement and assessment techniques, semi constructed interview questions were prepared. Specialist views were taken into consideration in order to determine whether they are suitable for the aim of the study or not.

FINDINGS

Within the scope of the study, it was found out how the alternative measurement and assessment techniques stated in science and technology curriculum are used in the books of different publishers, the techniques used in the textbooks and workbooks are shown in the table given below. Engaging questions existing in the context and in the activities are not included in analyses.

Table 2. Measurement and assessment techniques used in textbooks and workbooks

	Open-Ended	●	●	●	●	●	●

In the books under examination, the measurement techniques measuring the process were generally included along with the outcome; however, it was observed that the measurement techniques for grouping, giving feedback and diagnosing, included at the core of the program, were nearly not used.

When Table 2 is analyzed, it shows that alternative techniques are used more frequently in the textbooks and workbooks of Publishers A and B than the textbook published by C. Besides, utilization frequency of alternative techniques was found to be more in workbooks than textbooks. Demonstration, concept map and table of semantic analyses techniques were used in all the textbooks and workbooks published by A, B and C. The diversity of the alternative techniques used by the workbook of Publisher A, was found to be more than the other textbooks and workbooks. Self assessment technique was used in all the workbooks of publishers; however this technique was not used in textbooks. In addition, group and/or peer assessment was only used in the workbook of Publisher A. Drama, interview, project, portfolio, KWL, group and/or peer assessment techniques was used both in textbook and workbook of Publisher C. As for portfolio technique, it was only used in the textbook of Publisher B.

Moreover, while Textbooks A and B include assessment questions at the end of every topic, Textbook C includes these questions only at the end of the unit. In addition, Textbook A and B have research and getting ready sections along with the topic; however, these sections don't exist in Textbook C.

When the teacher's guide books of these three publishers examined, it was found that teachers were informed on how to use and assess alternative techniques by instructions. Moreover, in all the three teacher's guide books self assessment, group and/or peer assessment, project assessment rubrics and student observation form and control form for experiments existed in order to be helpful for the teachers.

Traditional techniques were used sufficiently in all the textbooks and workbooks of publishers.

In addition to the measurement and assessment techniques referred to above, open ended questions that can attract students' interest was used too often in the context of all the textbooks of publishers. Besides, textbooks were also analyzed in order to see whether they may promote a student's active role in the learning process or not. Textbooks should ask students to perform reasoning (minds-on) activities as well as practical (hands-on) activities and this should be done before presenting them with the content to be learned. (Leite,1999).

Table 3 shows the results of the analysis concerning both the existence of learning activities (minds-on and hands-on) and the location of the content with reference to the activities included.

Table 3. Requirement of students' activity

Categories of analysis	A		B		C	
	TB	WB	TB	WB	TB	WB
Minds-on activities	12	155	3	170	-	173
Hands- on activities	67	16	52	7	62	9
Total	79	171	55	177	62	182
Content is given:						
-before the activities	•	There is no content in workbook	•	There is no content in workbook		There is no content in workbook
-after the activities						
-sometimes after; sometimes before					•	

The analysis of the data given in Table 3 leads to the conclusion that all textbooks include some activities to be carried out by the students. Textbook C is the only one that does not include minds-on activities to be performed by its users. Hands-on activities are frequently used by all textbooks; in addition, minds-on activities are preferred more often in all the workbooks. Textbooks A and B always present the content needed before introducing the activities, whereas textbook B present the content sometimes after and sometimes before introducing the activities.

New Science and Technology Curriculum aims to educate all students in being science and technology literates whatever their individual differences are. The curriculum not only aims to convey today's knowledge to the students but also it aims students to be inquiry, to make connections between daily life and science topics, to be able to use scientific methods when confronted with daily problems and to be able to evaluate events in the view of a scientist. With this purpose the curriculum advices textbook authors to use "minds-on activities" and "hands-on activities very often (MEB, 2005).

FINDINGS OBTAINED FROM QUESTIONNAIRES

The teachers' profiles and their participation status to in-service training about alternative measurement and assessment techniques are shown in Table 4.

Table 4. The teachers' profiles and their participation status to in-service training about alternative measurement and assessment techniques

Characteristic	Categories	f	%	Characteristic	Categories	f	%
Gender	Male	168	56	Participation status to in-service training about alternative measurement and assessment techniques	Yes	230	76.7
	Female	132	44		No	70	23.3

Data given in this table shows that 56% of the teachers participated in the questionnaire were male and 44% were female. Also 76.7% of the teachers attended in-service training about alternative measurement and assessment techniques.

The common views found out with respect to the measurement and assessment aspects of textbooks and workbooks at the end of the questionnaire review made within the scope of the study are stated in the following Table 5.

When the views of science teachers about measurement and assessment techniques used in textbooks and student workbooks are examined, it is observed that teachers found the books generally sufficient for most criteria. Nevertheless, it is an engrossing finding that the rate of teachers thinking that the books concerned require to be developed in terms of measurement instruments' level of measuring critical gains exceeds 50%. Hence, this should be taken into account in the student workbooks to be rewritten or revised.

Teachers' positive and negative views about alternative measurement and assessment techniques used in textbooks and workbooks are presented in Table 6 based upon interview data.

Table 5. Views of science teachers about measurement and assessment aspects of the textbooks (TB) and workbooks (WB) of science and technology course

Assessment Criteria for Science and Technology Books		Sufficient		Should be Developed		Total	
		TB	WB	TB	WB	TB	WB

		50.7	52.0	49.3	48.0	100.0	100.0

Table 6. Teacher's views about the measurement and assessment techniques used in textbooks and student workbooks

Positive aspects	Negative aspects
• All types of questions were used and individual differences were taken into consideration. • Measurement and assessment materials attract attention of students more • It gives students opportunities to self assess and fulfill their needs. • It helps teachers to reform themselves. • Measurement and assessment is not fearful, it is informative and enhancive. • Diversity of assessment identifies the student and makes it easy to assess. • Not only product but also process is assessed. • Measurement and assessment materials also help to improve teachers. • Measurement and assessment materials used in textbooks and workbooks are sufficient and they reinforce learning. • Questions based on estimation and discussion in the context helps to measure and assess. • Measurement and assessment activities are appropriate for the levels of students and they identify what they learnt. • They give students opportunities to self assess and they are convenient for multiple intelligence.	• Assessment forms are excessive and very difficult to implement them all. • The consumption of paper and printed documents and the cost of photocopying increase. • Due to crowdedness of classrooms, assessments are made without considering the goal properly and completely. • Lack of materials affects assessment negatively. • When self assessment forms are filled in by the students, they are not objective enough • It is impossible to prepare, and keep all the forms. • Measurement and assessment takes too much time and stationery costs a lot. • Some concept maps are complex. • Alternative measurement and assessment techniques are not sufficiently known and in-service trainings are inadequate. • Assessment takes a very long time in crowded classes. • It is difficult to check and assess projects and performance tasks.

When Table 6 is examined, it is understood that teachers find the measurement and assessment techniques used in textbooks and workbooks positive but they do not feel themselves sufficient concerning alternative measurement and assessment techniques. On the other hand, it was observed that teachers stated negative factors as crowdedness of classes, consumption of paper, photocopy and printed documents and insufficiency of time.

DISCUSSION AND CONCLUSION

Alternative measurement and assessment techniques are essential subjects, upon which most curricula in the developed countries of the world. In elementary school curricula that are put into practice in Turkey in 2005-2006 educational year, teachers were asked to use alternative measurement and assessment tecniques besides using traditional ones.

As a result of analyzing alternative measurement and assessment techniques used in the books, it was seen that while there are some points completely in accordance with the principles of constructivism, there are also some insufficient and inadequate points. For instance; in the textbooks, measurement and assessment materials used in textbooks and workbooks can help students both to internalize information easily and to integrate information related to tools used in daily. Moreover, it was observed that textbooks and workbooks are adequate to include measurement and assessment materials. However, the workbook activities are considered to have a better design to address to the students with different intelligences (Gardner & Hatch, 1989), in comparison with the activities in the textbook. Furthermore, it was found that the workbook is especially better in terms of using alternative measurement-assessment techniques and methods.

Additionally, some sufficient and insufficient points in the textbook and workbook are revealed as a result of analyzing teachers' views about the sufficiency of alternative measurement and assessment techniques used in the books.

One of the most frequent positive views about measurement and assessment concerns the renewal of the curriculum that evaluates both the result and the process. Another one is that the books include activities checking the pre-knowledge. Moreover, performance tasks and projects are considered positive by the teachers. Student self-assessment and group / peer assessment are further positive aspect of the books. The most common negative view on measurement and assessment is that the scoring criteria are not explanatory, graded scoring key is not user friendly and the number of assessment forms is excessive. The reason why the teachers assess in this fashion might be that they think all the forms should be frequently used. Moreover, the teachers might have neglected that the forms are not necessarily used for all the students at the same time. Another negative aspect in terms of measurement and assessment is that the students face difficulties in assessing themselves and their group members. Finally, the troubles in the use of concept maps increase in paper consumption, preparation of Secondary School Entrance Exams according to the old elementary education curricula are among the most frequently encountered negative views. In order to overcome this problem, a secondary education pass system, based on the renewed elementary education curricula, was put into effect in 2007-2008 session for admitting the students to secondary education. Therefore, it is aimed to apply the education curricula successfully and to increase the use of textbooks that are one of the basic tools of this application.

MORAL REASONING PATTERNS OF PRE-SERVICE SCIENCE TEACHERS TOWARD LOCAL AND NON-LOCAL ENVIRONMENTAL PROBLEMS

Busra Tuncay	Ozgul Yilmaz-Tuzun	Gaye Teksoz

tbusra@metu.edu.tr	ozgul@metu.edu.tr	gtuncer@metu.edu.tr

ABSTRACT

In the study, the assumption that there may be differences in moral reasoning patterns (i.e. ecocentric, anthropocentric, non-environmental) of people toward local and non-local environmental problems was tested. In the first two administration periods, one hundred and twenty pre-service science teachers listed their concerns regarding four non-local and four local environmental problems. Then, interviews were conducted with 16 of the participants (8 male and 8 female), four from each grade level, who were randomly selected among the volunteers. Content analyses were carried out on participants' written responses to the given local and non-local environmental problems, and qualitative data analysis was implemented to interpret the interviews and examine participants' environmental moral reasoning deeply. Analyses revealed that participants of the study were more concerned about the effects of the environmental problems on environment itself when the problems were non-local, whereas their anthropocentric concerns were higher for local environmental problems than non-local ones. Found differences indicate the importance of situational factors for environmental moral reasoning and point out the necessity of improvement in coverage of local environmental issues as well as non-local ones in various aspects.

Keywords: *Moral reasoning, local environmental problems, non-local environmental problems, teacher education.*

INTRODUCTION

Many years ago, it was stated that the main reason of the environmental crisis, which we still try to cope with today, was human behavior and the best way to solve many environmental problems was described as educating people and creating changes in their behaviors so that they become more environmentally friendly (Maloney & Ward, 1973). At this point, Gurevitz (2000) argued that affective forms of environmental education encourage individuals to engage in pro-environmental behaviors more when compared to approaches aiming to increase amount of scientific knowledge about environmental issues in their learners. Similarly, many studies and important reports on environment reveal the importance of affective approaches, especially integrating environmental ethics in environmental education. For instance, in Tbilisi declaration (1978) it was indicated that environmental education should educate individuals in a way that they can understand the problems of our world and protect environment with regard to ethical values.

In addition, owing to the comprehensive characteristics of environmental problems, which have political, economical, and social aspects (Chan, 1999), it can be stated that environmental knowledge should also include moral decisions about values and powers (Hausbeck, Milbrath, & Enright, 1992) as well as basic scientific knowledge. Furthermore, research show that in addition to these various aspects of environmental problems, there are additional factors that are affective in people's perceptions related to environmental problems such as the risks people attach to the issues (Bamberg, 2003).

Correspondingly, researchers of the present study hypothesized that there may be some differences in moral reasoning patterns of people toward local and non-local environmental problems due to the possible differences in the risks attached to them. In fact, findings of some research strengthen this assumption. For instance, in their study, Duan and Fortner (2005) concluded that there were some differences in Chinese college students' perceived risks of global and local environmental issues, such as significance and danger as well as certainty, complexity, and tangibility.

In accordance with the aim of the study, pre-service science teachers' moral considerations related to four local and four non-local environmental cases about deforestation, e-waste, oil spill, and global warming environmental problems were examined. The cases that exist in the country where the study took place were defined as local, and the other ones as non-local.

Where 'moral reasoning' is defined as a thinking process with the objective of determining whether an idea is right or wrong (Littledyke, 2004), the researchers of the present study described 'environmental moral reasoning' as the thinking process of determining whether an idea/action is right or wrong with regard to environmental improvement and protection. Since people have different motives, or reasons, for valuing nature (Bjerke & Kalternborn, 1999), they may develop different reasoning patterns toward environmental problems. Likewise, as have been stated previously, the researchers of the study aimed to examine whether these motives or reasons that the participant pre-service science teachers possess were different for local and non-local environmental problems or not.

Similar to Kortenkamp and Moore (2001), three categories were used for labeling moral reasoning patterns of the participants: ecocentric (valuing nature due to its intrinsic value), anthropocentric (belief in the importance of environmental quality due to its usefulness to humans), non-environmental (concentrating on other aspects of the environmental problems such as laws).

Consequently, the present study is believed to have important contributions to the development of effective environmental education programs with its findings and implications by revealing the importance of affective approaches, namely morality, for people's perceptions about environmental problems and their motivation to exhibit pro-environmental behaviors once more. Furthermore, the study has additional significance for the improvement of environmental education owing to its sample being pre-service science teachers. In the view of the fact that pre-service science teachers will be role models for their own students in future and have active roles in achieving ultimate goal of environmental education, which is educating environmentally responsible citizens (Culen, 2001), determining their moral approaches toward environmental problems and giving feedback to educators at education faculties of universities is important.

Finally, the findings of the study will reveal some implications about the relationship between culture and environmental moral reasoning, and contribute to the related literature significantly because it is seen that although number research conducted on this subject is increasing in an encouraging manner it is not satisfactory, especially in non-western countries. Therefore, examining moral reasoning patterns of pre-service science teachers and investigating possible factors that may influence these patterns in the context of a non-western country seems to be consequential.

METHOD

SAMPLE

The participants of the study were 120 pre-service science teachers with a mean age of 22.08 years (N_{male}=31, N_{female}=89). They were first, second, third, and fourth grade university students who enrolled in elementary science education department of a large research oriented university and constituted 60% of the accessible population (N_{male}=62, N_{female}=138). In addition, among the volunteer participants, 16 of them (N_{male}=8, N_{female}=8) were selected in equal numbers from each grade level and interviews were conducted to follow up and refine the quantitative findings of the study.

INSTRUMENTS

For the study, four local and four non-local environmental cases about deforestation, e - waste, oil spill, and global warming environmental problems were prepared by the researchers. Based on the importance of using real life problems for the effectiveness of environmental education (Tuncer & Erdoğan, 2006), the researchers of the study preferred to use real environmental cases rather than hypothetical dilemmas for examining moral reasoning patterns of pre-service teachers toward the presented environmental problems. In the same way, information given in the texts related to the cases were reached from sound resources including articles presented in various databases, important reports related to environment, and declarations of Ministry of Environment and Forestry of the country. After the cases were prepared by the researchers and an agreement was established between them, the final structures of the cases were presented to an expert committee. The experts in the committee were asked to examine the cases in terms of the sufficiency of the given information as well as equivalence of the amount and type of the enhanced information such as problems' effects on humans and on environment itself.

As a second instrument, Moral Decision-Making Interview (MDMI) protocol developed by Sadler and Zeidler (2005) was used with some adaptations that aimed to help interviewees focus on the eight environmental cases regarding the four environmental problems. The aim of the interviews was to examine moral reasoning of the participants in a deeper manner and reveal the possible factors that influenced their moral reasoning patterns toward local and non-local environmental problems. Language of the cases and the interview protocol were in English. This situation does not seem to be a limitation for the study because since the education language of the university where the study took place is in English, participants had the necessary competencies in comprehending and responding to the data collection instruments. Even so, interviewees responded to the questions asked during the interviews in their native language so that they were more relaxed and reflected their opinions and feelings more comfortably.

DATA COLLECTION AND ANALYSES

Data collection period of the study took two semesters (2008-2009 Fall, 2008-2009 Spring) to be completed and was carried out in two administration periods apart from the interviews. In the first administration period, participants' responses to non-local environmental cases were collected, and after two months, local environmental cases were administered. For each administration, the participants were asked to list and explain their considerations that concerned them most about each environmental case. With the two month of the time interval between administration of non-local and local environmental cases, possible interaction between participants' responses to the cases was aimed to be eliminated. After the administration of the cases, e-mails of the participants who were willing to participate in the follow up interviews were collected and meeting hours were arranged with 16 of the volunteers. Based on findings of some research that resulted in different moral reasoning patterns in males and females (e.g., Ford & Lovery, 1986), equal number of males and females were invited to the moral reasoning interviews: two males and two females from each grade level. The interviews were semi-structured and lasted about 30-45 minutes.

Content analysis was carried out on the written statements of participants reflecting their concerns about the distributed environmental cases and each statement was coded as ecocentric, anthropocentric or non-environmental according to their meanings, which were explained in the introduction part of the paper. An inter-rater agreement of 95% was achieved after the coding process of the responses by the researchers. Then, the calculated frequencies of each moral consideration category were entered to the Statistical Package for Social Sciences (SPSS) version 15.0 for Windows for descriptive and inferential analyses.

In addition, Miles and Huberman's (1994) approach of qualitative data analysis was utilized for the analyses of the interviews, which were audio-taped and transcribed by the researchers in order to make sense of the obtained data. Throughout the analyses, the second and third authors of the research reviewed 20% of the interviews and the agreement in the coding of the statements was found to be 87%. The remaining analyses were performed by the first author according to the agreed coding.

RESULTS

Content analysis of the participants' responses regarding their concerns about the presented environmental cases demonstrated that they generally tended to concern more about the problems' effects on environment itself rather than the harms people had to face due to these problems or problems' other aspects such as being against laws or rules of the society. Distribution of ecocentric (eco.), anthropocentric (anthro.) and non-environmental (NE) moral considerations as well as total number of concerns (total) stated for local (local) and non-local (Non-local) environmental cases, and for the environmental cases when they were taken as a whole (TOTAL), regardless of their being locality are demonstrated in Figure 1. Corresponding values represent the mean values of the calculated frequencies for each moral consideration category.

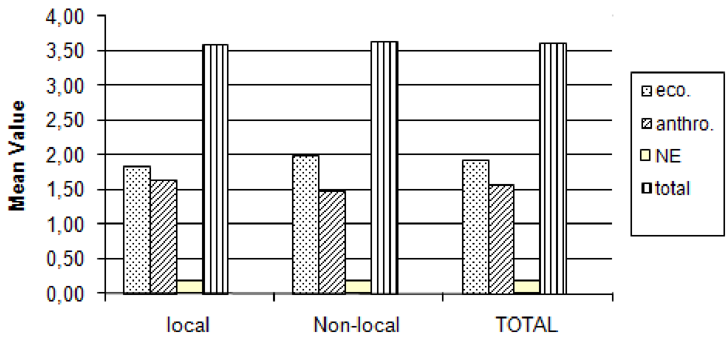

Figure 1. **Mean values for ecocentric (eco), anthropocentric (anthro.), non-environmental (NE), and total (total) moral considerations.**

As have been stated previously, the values show that pre-service science teachers who participated in the study exhibited mostly ecocentric moral concerns, then anthropocentric concerns and finally non-environmental concerns for both local and non-local environmental problems. Nevertheless, oil spill case among the non-local environmental cases and global warming case among the local cases received higher anthropocentric concerns than ecocentric concerns by the participants. Mean values calculated for ecocentric (eco.), anthropocentric (anthro.) and non-environmental (NE) moral considerations as well as total number of concerns (total) stated for each environmental case are tabulated in Table 1.

Table1. ***Mean Number of Moral Considerations for Non-local and Local Environmental Problems***

		Deforestation	E-waste	Oil spill	Global Warming	Average
Non-local	Eco.	1,92	2,10	1,73	2,25	2,00
	Anthro.	1,38	1,33	1,77	1,43	1,48
	N.E.	0,32	0,21	0,17	0,03	0,18
	total	3,58	3,56	3,65	3,68	3,63
Local	Eco.	2,16	1,94	1,75	1,45	1,83
	Anthro.	1,51	1,19	1,73	2,07	1,63
	N.E.	0,07	0,50	0,15	0,01	0,19
	total	3,68	3,50	3,61	3,54	3,59

Furthermore, analyses revealed that global warming problem among the non-local environmental problems and deforestation problem among the local environmental problems received more concerns by the participants. In addition, comparison of the mean number of moral considerations for local and non-local environmental problems resulted in some remarkable findings. It was found that participants' ecocentric concerns were higher for non-local environmental problems than for local ones. Similarly, their total concerns toward the presented non-local environmental problems were higher than for local environmental problems. Conversely, they demonstrated more anthropocentric concerns toward local environmental problems than they did for non-local environmental problems, which means they paid more attention to the effects of environmental problems on humans when the problems were in their own country.

Further inferential analyses, namely dependent samples t-tests, conducted to test the significance of the differences between moral reasoning patterns of the pre-service teachers toward local and non-local environmental problems demonstrated that there was a statistically significant difference in ecocentric moral considerations ($p = .043$) of the participant pre-service science teachers. On the contrary, differences in their anthropocentric ($p = .109$) and non-environmental ($p = .946$) moral considerations as well as total environmental concerns ($p = .453$) were not statistically significant.

Finally, follow up interviews conducted to investigate moral reasoning of the participated pre-service teachers deeply and examine factors that influence their moral reasoning patterns also supported the results mentioned above. They were more concerned about the effects of the environmental problems' effects on environment itself when the problems were non-local, whereas they exhibited more anthropocentric concerns toward the local environmental problems. Statements of one of the participants clearly supports this argument: " I know… maybe I should be equal distance to the two situations [means local and non-local] but I care my own county's people more than animals, or plants in this country. I mean… they are our people. However, when it comes to another country… my logic comes before my emotions. Plants and animals are more important for ecological balance."

In addition, some possible reasons for this difference arose from the interviews. Some participants implied media for the difference in their concerns toward local and non-local environmental problems, as demonstrated by the following quote: "…In news while showing these kinds of things [means news on environmental issues] in the world, they mostly show animals who are suffering. For instance, when I think about melting of glaciers there is a picture in my mind: a lonely polar bear on an ice cap looking its surrounding… so, people become unimportant. However, for example, when there is a water shortage, the most important thing seems to be people. In news, you see farmers who are in bad conditions for example and since you, yourself, cannot find water, you do not care animals, or plants."

DISCUSSION

Findings of the analyses conducted to examine environmental moral reasoning of pre-service science teachers who participated in the study showed that they were more concerned about the effects of environmental problems on environment itself, rather than their effects on humans or the non-environmental aspects of these issues such as being illegal. This finding differs from some previous research conducted in other countries implying possible effect of culture on moral reasoning patterns. For instance, contrary to the participants of the present study, undergraduate students who participated in the study of Kortenkamp and Moore (2001) exhibited non-environmental moral reasoning with the highest frequency. Moreover, mean number of their anthropocentric reasoning were found to be higher than mean number of their ecocentric reasoning.

In addition, as have been hypothesized at the beginning of the study, differences were found in the mean number of ecocentric, anthropocentric, and non-environmental concerns of the participants toward local and non-local environmental problems. This finding is supporting Kortenkamp and Moore's (2001) study by revealing the importance of situational variables, such as locality of environmental problems, for environmental moral reasoning patterns once more.

In their study, Kortenkamp and Moore (2001) showed that information enhancement about the effects of environmental issues on environment and on humans affected their participants' moral reasoning categories. Their participants demonstrated more ecocentric concerns when information about the effects of the environmentally damaging actions on environment was enhanced in the distributed dilemmas. Correspondingly, as Chan (1999) stated, wide media coverage of environmental issues such as global warming and depletion of ozone layer focus people's attention to these environmental issues and when people perceive environmental issues more significant and dangerous, they become more concerned (Duan & Fortner, 2005). These research explain the higher ecocentric concern of the participants exhibited toward non-local environmental problems presented in throughout present study. Since non-local environmental problems, such as water scarcity due to global warming, and deforestation of Amazon rain forests take more place in media and their environmental significance are presented more, study's participants may have stated more ecocentric concerns to the non-local issues than local ones presented in the study. On the other hand, as also seen in the follow-up interviews, local environmental problems take more place in media with their impacts on humans and the economy of the country since the country is a developing country with many economical problems. Therefore, participants of the study paid more attention to the effects of local environmental problems on humans more and exhibit anthropocentric moral considerations toward these issues more.

To sum up, this study is an indication of the importance of situational factors for people's environmental moral reasoning and the necessity of improvement in coverage of environmental issues on local environmental issues as well as non-local ones in various aspects. Since, different people may have different motives, or reasons, for valuing nature (Bjerke & Kalternborn, 1999), if we educate our teacher candidates who are aware of all of the aspects of environmental issues such as social, economical, environmental, and legal, they will be able to educate their own students accordingly, and thus promote environmentally friendly behaviors in the society.

ASSESSING PRESERVICE SCIENCE TEACHERS' NATURE OF SCIENCE UNDERSTANDINGS: FROM EXPLICIT TO TACIT

Halil Turgut

Marmara University

halil.turgut@marmara.edu.tr

ABSTRACT

The importance of accurately teaching NOS to individuals is widely recognized and the issue of exposing and assessing the NOS understandings, especially the tacit ones, seem to be crucial. The purpose of this study, therefore, was to explore both the explicit and more deeply-held tacit NOS understandings with an interpretative research design. Thirty preservice science teachers were enrolled in a STS course in the context of demarcation of science from pseudoscience. Open ended questions and activity sheets prepared by participants constituted the data sources which were analyzed qualitatively. The results of the research implied that participants' explicit NOS understandings were naive for various aspects with an absolutist view of scientific knowledge in a belief-free context that can be gained through a universal, unique scientific method involving a set of fixed stages. The tacit understandings were seen to be in accordance with these explicit ones and portray a general view of science based on "discovery" of "facts" without any interpretation. Solely, direct observations or experiences of "facts" without any inferences were seen to be viewed as doing science by participants. Morever, the participants' tacit understandings seemed to form the basic rationale for their explicit views which should be examined further.

Keywords: *NOS Understandings, Explicit, Tacit*

INTRODUCTION

The importance of accurately and deliberately teaching NOS to individuals is widely recognized as evident in science education reform documents (Clough, Olson, 2008; Meichtry, 1993; Kang, Scharmann & Noh, 2005) and the development of individuals' understandings of the NOS has been considered as an important aim of science instruction (Duschl 1990; Meichtry 1993; Kang, Scharmann & Noh 2005). However, little done to provide some instructional methods to enhance the development of the NOS understanding (Scharmann, Smith, James & Jensen 2005) and as a consequence of diverse definitions developed over several decades, researchers had been seen to not share a common conception of NOS (Abd-el Khalick, Bell & Lederman 1998; Kang, Scharmann, Noh 2005). The philosophers, historians and sociologists of science are quick to disagree on specific issues (Lederman, Abd-El-Khalick, Bell & Schwartz 2002) and have proposed different views about what science is and how it works with different rationales. But, most of these disagreements about the NOS are seen to be irrelevant to science education (Abd-El-Khalick, Lederman 2000) and the shared wisdom at a certain level of generality about the NOS among the philosophers of science (Smith, Lederman, Bell, McComas, & Clough, 1997) constituted a common ground for science education.

Based on this common ground, the nature of science (NOS) is often seen to be used to refer to both the epistemology and sociology of science as a way of knowing including the values, beliefs inherent to scientific knowledge (Lederman, 1992), ontological foundations of science (Clough, Olson, 2008) and understandings about the organization of science as an enterprise (Ryder, Leach, & Driver, 1999). Such a perspective underlines some aspects such as; (i) tentativeness, (ii) empirical nature, (iii) theory-laden nature, (iv) socio-cultural embeddedness; (iv) myth of a universal scientific method; (v) roles of hypothesis, theories and laws; (vi) creativity and imagination and, (vii) persuasive communication, for a basic understanding of the NOS (Smith, Scharmann 1999; McComas, Clough & Almazroa 2000; Lederman, Abd-El-Khalick, Bell & Schwartz 2002). So, without ignoring the philosophical debates about specific issues and the related complexity, these aspects mentioned in many documents should be claimed to establish an acceptable ground for the NOS (Lederman, Abd-El-Khalick, Bell & Schwartz 2002), which is crucial for clarifying the intention teaching.

The search of related literature indicated two general positions for such an aim of teaching the NOS which Bravo (2004) called as ‘curriculum perspective’ and ‘meta-theoretical perspective’. According to curriculum perspective, the focus is on the intrinsic value of the NOS for the education of citizens, which based on democratic and cultural arguments. An understanding of the NOS is evaluated as necessary for making sense of socioscientific issues, participating in the decision-making process (Driver, Leach, Millar & Scott 1996; Zeidler, Walker, Ackett & Simmons 2002) and seen to be crucial for effective local and global citizenship (Smith & Scharmann 1999). Being an educated citizen of the twenty-first century is not claimed to require just to know science but also to know about science; how it is created, how it evolves through history and how it relates to society and culture (Bravo, Merce & Anna 2001). On the other hand, in the meta-theoretical perspective NOS is assumed to represent a second order reflection on the content and methods of science that positively contributes to teachers’ autonomy especially when transforming scientists’ science into school science (Bravo 2004).

However the results of previous researches concerned with improving students’ understanding of the NOS indicated that students from various age groups and even teachers possess both inaccurate and inappropriate views of NOS regardless of the instruments or methods used in investigations (Lederman, 1992; Duschl, 1990; Abd-El-Khalick, & Lederman, 2000). Such a failure had explained by the help of the view that perceptions about the NOS are well assimilated into mental structures and resistant to change (Meichtry, 1992). Hence, any expected development in the NOS understandings firstly requires the exposing of the current perceptions to challenge or alter and this issue addresses the effective assessment of NOS understandings which still remains equivocal (Lederman, Wade, & Bell, 1998; Craven, Hand & Prain, 2002). An important aspect in this context is related with the nature of assessment and the underlying assumptions of the instruments used that are either standardized or open ended but an additional one should also be considered; the distinction between explicit and tacit understanding forms.

The search on the assessment of the NOS understandings indicate the use of standardized or open ended questionnaires with a general tendency towards assessing the explicit understandings which individuals can immediately access and verbalize while communicating with others. However, the assessment of tacit understandings which are unarticulated but are demonstrable by use and action (Polanyi, 1966) are seemed to be overlooked. Although has been used in various ways, tacit knowledge is seen to be defined as the procedural knowledge (rather than the factual one) about the things that have personal importance for the learner and assumed to be learnt without the help of others or any explicit instruction (Sternberg et al., 2000; Torff, 1999) and hence, should be held seriously in educational practice as intuitive conceptions. The purpose of this study, therefore, was to expose and assess both the explicit and more deeply-held tacit NOS understandings of the pre-service science teachers in which various aspects were considered for a basic understanding of the NOS.

DESIGN ISSUES

The present study made use of an interpretative research design with a qualitative data analysis approach (Strauss, Corbin, 1998) to examine both the explicit and tacit perceptions of pre-service science teachers about the NOS.

PARTICIPANTS AND CONTEXT

Participants of this research were 30 pre-service science teachers of 13 males and 17 females with ages ranged from 20 to 22 at the undergraduate level in a state university, in Istanbul, Turkey. They were enrolled in the Science-Technology-Society course, taught by the researcher for three hours a week for a period of 12 weeks. All the participants had completed science courses of the teacher education program such as physics, biology and chemistry but none of them had any prior instruction related with the nature, history and philosophy of science. The research covered the first three weeks of the course, the introduction phase, in which the NOS as the core concept under the heading of scientific literacy and the issue of the demarcation of science from pseudoscience as the context of the course were presented to participants. In this phase, any informative instruction about any aspect of NOS did not performed in the class but a common understanding about the context of demarcation of science from pseudoscience was tried to be constructed conceptually. For this, the case of being pseudoscientific was introduced to participants; it defined as having the claim of being scientific although do not meet various standards mentioned by philosophers of science (Preece & Baxter, 2000), and some samples, especially the ones which placed in the popular media such as astrology were briefly overviewed in the class. Within this process, the participants did not have any instruction about the criteria proposed by various philosophers of science and the arguments about the issue of demarcation but tried to be informed about the term pseudoscience to establish a common ground for the context. At the end of this process, the participants were asked to design an activity which should be performed in the elementary science classes, to provide students a basic understanding about the main properties of scientific enterprise and the criteria for demarcating it from pseudoscience.

DATA SOURCES AND ANALYSIS

Two data sources were used in this research to expose and assess the participants' both explicit and tacit understandings about the NOS. The first data source was the "*Views of Nature of Science Questionnaire-C* (VNOS–C)" that developed by Lederman et al. (2002), that based on various aspects of NOS such as the empirical nature of scientific knowledge, the theory-laden nature of observations, the socio-cultural embeddedness of scientific knowledge, scientific method/methods and the scientific theories, laws. The intention of this questionnaire was to examine the explicitly pronounced NOS understandings of the participants and was given to them at the first week of the course. So, these explicit understandings were thought as the experience based beliefs of the participants about the NOS, which were developed within their formal education up to this course. The second data source was the set of activity sheets prepared by the participants to emphasize the criteria for demarcating science from pseudoscience, after the introduction of the concept of pseudoscience in the course. With the analysis of these activity sheets, the determination of the tacit understandings of the participants about the NOS was aimed. These activity sheets were examined to elicit the participants' tacit understandings about science as an enterprise, which did not pronounced explicitly but reflected in the process of demarcating it from pseudoscience, in action.

Both data sources were analyzed comparatively for each participant and the analyses began with the search of patterns in the data to derive a coding system. For this, the responses for the open ended questions and the activity sheets of each participant were read and any bit of information related with the issue stated by a word, a sentence or a whole paragraph was used as a conceptual construct to be coded. The list of codes established was then narrowed and a new list of codes developed to sort the data mechanically (Gay, Mills & Airasian, 2006; Bogden & Biklen, 2007). With the help of this sorting process, various themes were determined and grouped into more abstract constructs; categories (Strauss, Corbin, 1998; Maxwell, 2005; Creswell, 2005). Then, the data sources were again examined to evaluate the success of these themes for representing the existing data. This process also provided the researcher to determine the frequencies of the emergence of these themes across the data sources. When it was satisfied that the themes represented the data adequately, the analyses process ended and the distribution of the participants for these themes were clarified.

RESULTS AND DISCUSSION

The results of the research presented in this section were grouped under two headings according to the understanding forms that examined about the NOS; (i) participants' explicit NOS understandings and (ii) participants' tacit NOS understandings.

PARTICIPANTS' EXPLICIT NOS UNDERSTANDINGS

The qualitative analysis of the responses given to VNOS-C questionnaire implied that the majority of the participants held naive views about several NOS aspects. An absolutist view of scientific knowledge in a belief-free context that can be gained through a universal, unique scientific method involving a set of fixed stages was seen to be central in these explicit NOS understandings.

The great portion of the participants (73%) defined science as a fact based discipline demanding certain answers to questions through an exact method which has unique steps to follow with experimentation at the core. With this perspective, the participants presented experiments as a "proving" process and dismissed the possible role of personal and social factors in the generation and validation of scientific knowledge:

> "Scientists seek the answers of questions about nature. They use the scientific method and make experiments about the facts. They prove their results and everyone accept the results without any discussion. Religion is personal, you can believe or not and in philosophy everyone can propose opinions" (P 11).

The difference of science from other disciplines was also seen to be based on this argument by the participants and religious, philosophical fields were labeled as disciplines which rely upon ideas and mere opinions contradictory to the definite conclusions of science that arrived by the use of facts. This idea of "proving" by experimentation and having certain answers at the end of the process was also seemed to be reflected in various aspects of the NOS understandings by the participants. The tentativeness of the scientific knowledge and the status of scientific laws, theories were among these.

A majority of the participants (80%) presented scientific knowledge and, especially scientific laws, as certain constructs which have been proved to be true many times by experiments and accepted by everyone without any doubt. In this context the tentativeness of the scientific knowledge was seen to be denied by this group of participants. Its certainty was claimed to be satisfied at the end of the process in which any socio-cultural factor do not have any role:

> "Scientists perform experiments about the facts they examine and after they perform many experiments they reach certain scientific laws which are valid for everyone at everywhere. They are then proved to be true" (P2).

It should be noted that nearly all the participants used the concept "tentativeness" in their discussions but it was seemed to be emphasized mainly for scientific theories which are not "proved" yet. They defined scientific theories as immature products of science, an intermediate phase in the generation of certain scientific knowledge, and presented the development of technology as the main reason for a possible rebuilding process.

In accordance with these arguments about the tentativeness of the scientific knowledge, theories and laws, a majority of the participants (87%) asserted a hierarchical relationship between scientific theories and laws. They claimed that the scientific theories, which are unproven yet and hence unaccepted by the scientific community, become scientific laws after they are confirmed by many experiments and researches:

> "Scientists have some theories and study on them. These theories should not be accepted by the community since they are not proved yet. But after they are tested with many experiments and are confirmed, they become laws which are certainly true" (P7).

The scientific laws were seen to be placed at the top of this hierarchy by the participants, as the knowledge of the facts which are certainly true in all cases. This approach was also seen to be informative for the participants' conceptions about the structure and the testing process of the theories. The idea of the confirmation of the theories by the experiments indicated that they conceived theories as some type of guesses which can be directly tested. They seemed to not have informed views about the structure of scientific theories and their roles in research. They thought that they learn theories, even the changed or rejected ones, to see their failures and to have the chance of evaluating the current ones.

These naive views about scientific theories and lack of information about their guidance in research were also indicative for participants' conceptions about scientists as observers. It was seen that a minority of participants (17%) presented informed views about the theory-laden nature of observations, which was not surprising in the whole group, where majority of the participants portrayed science as a process of proving of the facts. The scientists were presented as blind minded researchers who are free from all the personal and cultural values/beliefs by this majority of the participants, as seen in their discussions about the dinosaur extinction controversy:

> "Although two different views exposed in this controversy, I think the problem here is the time period they are talking about. It was a long time ago and we cannot be sure what happened at that time. But, when enough data is found one of them will be accepted" (P21).

The participants emphasized mainly the lack of data as a reason for such a controversy and the impossibility of being sure about an issue that happened a long time ago, but did not exhibit any understanding of the role of prior knowledge and scientific theories which influence scientists' interpretation of current evidence.

The majority of participants' (80%) understandings about the models, the structure of atom in this case, were also seen to be naive, which also presented some cues that reflected their views about the creative and imaginative NOS. The participants indicated that scientists are generally sure about the structure of atom, as they performed many experiments and gained data:

> "The scientists performed some experiments with alpha particles and collect data. They performed many such experiments, corrected previous failures and after that they become sure about the structure of the atom" (P19).

Although a limited portion of the participants (20%) asserted that the views about the structure of the atom should be altered in the future with the advance of technology, the reason they proposed was seen to be based on having some additional data. The creative and imaginative aspects of NOS (in the construction process of the models and theories) were not explicitly emphasized in any of the participants' responses. The general tendency was to discuss the scientific models as constructs that represent the reality as it is. The use of creative and imaginative NOS by the great portion of the participants (70%) was seen to be limited with designing of the experiments to collect data, as a step in the process of scientific research.

The participants' discussions about the universality of the science, finally, were seen to be informative for their naive understandings about many aspects of the NOS. Nearly all the participants asserted a "universal science" understanding, which is totally free from social and cultural values, at least as an end product. Although some of the participants (23%) gave credit to the role of socio-cultural factors in the scientific enterprise, their comments were mostly related to the motivating aspect of these factors for scientists:

> "A research area can be supported in some countries whereas forbidden in the others. Socio-cultural values can direct the interests of the scientists or the distribution of the funds. However, they cannot be determinant in the process of research, for the acceptance or rejection of results" (P18).

The main rationale that frequently observed in the participants' responses for the universality of science was seen to be based on the objective reality it examines. They stated that science is about the facts, which are the same everywhere, and mainly gave the sample of the free fall of a mass. It is noted that all the masses will fall down, when dropped, in the same manner on the earth wherever you are. The common failure of the participants in this context was seen to be about the discrimination between the objectivity of the phenomena that scientists examine and the science itself as a complex process. As a result, they could not exhibit an informed understanding about science as an enterprise which is embedded in a socio-cultural milieu that impacts the NOS.

PARTICIPANTS' TACIT NOS UNDERSTANDINGS

The qualitative analysis of the activity sheets prepared by the participants to demarcate science from pseudoscience implied that the majority of the participants portray a general view of science which based on the discovery of physical phenomena without any interpretation. Solely, direct observations or experimentations of "facts" without any inferences such as buoyancy and expansion of metals were seen to be viewed as doing science by them.

The activities planned by the participants were seen to be grouped into two according to their strategies for developing an understanding of demarcation of science and pseudoscience. The first group (60%) was directly focused on the comparisons between scientific knowledge claims and pseudoscientific ones. The generally used scientific knowledge claims in this group were about directly observable and sensible physical phenomena, such as the expansion of heated metals. The contrary pseudoscientific ones in these comparisons were mostly astrological claims, such as the behavioural properties of individuals related to their astrological signs. The following example should be viewed in this manner:

> "Firstly the students in the class will perform an experiment about the expansion of the heated metals. They will take a piece of metal rod and measure its initial length and temperature. Then they will heat it and again measure its current length and temperature. In the last step, they will compare its initial and last length in accordance with the increase in its temperature. They will see that the scientific knowledge about the expansion of heated metals is proved by this experiment. In

> the second phase, the students will be asked to write their behavioural properties and date of birth on a piece of paper. Then these papers will be collected and grouped according to the dates of birth with the help of students. In the next step they will be examined to determine if the behavioural properties are directly related to the dates of birth. The students will realize that the claim of astrology for such a relation is inaccurate and pseudo" (P28).

The other sample activities planned in this first group were also seen to be very similar in their nature. The scientific units in the comparisons were based on either direct measurements or observations of objective phenomena such as the boiling of water at 100^0C. However, the pseudoscientific units were astrological claims including subjective constructs such as behavioural properties which tried to be questioned with the students in the class. These activities had indicated that the participants had perceived the scientific claims as absolutely true and strictly verifiable. Objective, reproducible and directly sensible matters of facts were thought as the only scientific without any emphasis on any conceptual or theoretical entity. Such an approach was seen to strictly bound science to a narrow, naive understanding which should be a source of crucial misperceptions about scientific enterprise.

The second group (40%) was seen to be more flexible for the comparisons they planned and took the units to be examined as disciplines rather than individual knowledge claims. The general tendency was determining some criteria for demarcation of science from pseudoscience and evaluating sample cases, such as alternative medicine and acupuncture, according to these criteria in class with the students. They planned to ask students a search for possible criteria of demarcation which then intended to discuss in the class to develop a common list. With the use of such a list of criteria, either small group discussions or whole class discussions on provided sources, such as texts about various fields of inquiry or videos, were designed.

> "I will ask students to search the properties of science and after they develop a list of criteria for being scientific, they will discuss them in small groups in the class. Then, these lists which will be developed in small groups will be discussed in the class as a whole and a final list of criteria will be determined. I will guide the students in the discussions and will provide them a sample case, alternative medicine, to be examined for being scientific according to the list of criteria developed in the class... Students will realize that alternative medicine is not accepted as scientific by the whole community and does not have powerful experimental support" (P 6).

Although this approach was seemed more powerful to develop a demarcation understanding for elementary science students, the fuzziness in the criteria to be determined and the inadequacy of the portion of this group to whole were evaluated as problematic. The participants either did not label any sample criteria for demarcation or listed objectivity, universality and experimentation as determinants of science or mainly highlighted the products of the disciplines to be examined according to these criteria. Any sign of perspective about the processes which the disciplines occupied while generating knowledge claims and about their ontological and epistemological assumptions were not seen in these activity plans. So, although the activities planned by the participants in this study were grouped into two according to their strategies, the rationale in their approaches for a discipline or individual knowledge claim to be scientific were seen to be similar.

CONCLUSION

The results of the research implied that participants' explicit NOS understandings were naive especially for the aspects; (i)theory-laden nature of observations, (ii)socio-cultural embeddedness of scientific knowledge, (iii)the myth of a universal scientific method and (iv)the roles of hypothesis, theories and laws in scientific enterprise. An absolutist view of scientific knowledge in a belief-free context that can be gained through a universal, unique scientific method involving a set of fixed stages was seen to be central in participants NOS understandings. The tacit understandings emerged with the analysis of activity sheets were seen to be in accordance with these explicit ones and portray a general view of science based on discovery of physical phenomena without any interpretation. Solely, direct observations or experiences of "facts" without any inferences such as buoyancy and expansion of metals were seen to be viewed as scientific activities by a majority of the participants, which is subject to the absolute confirmation. So, the results of the research indicated that participants' tacit understandings seemed to form the basic rationale for their explicit views which should be examined further by the help of activities planned by them to have a chance of developing naive beliefs. Within such a process, the participants should be provided with explicitly discussed NOS aspects that based on the reflections of their tacit understandings. The development of tacit understandings in action would then be transferred into explicit interpretations of NOS.

LEARNING TO CONNECT DIFFERENT CONTEXTS: NEW PERSPECTIVES THROUGH KNOWLEDGE TECHNOLOGIES

Maja Bračič Lotrič

tanja.urbancic@ung.si

ABSTRACT

Understanding complex phenomena and solving difficult problems requires not only specialized scientific knowledge, but also cooperation across the borders of disciplines and particular contexts. In this paper we discuss why connections across different contexts are important, how knowledge technologies can help in recognizing and establishing these connections, and how we prepare our students for such tasks. Recent technical solutions have potential of becoming general methods for coping with increasing amounts of specialized knowledge. As such, they should become a part of a methodological repository for students and professionals in all fields of science. At the same time, students should know that technical solutions go hand in hand with non-technical development, so this should be taken into account in developing curricula. Some solutions implemented in the Engineering and Management Master's study programme are presented and analysed, including three year experience with student projects, characterized by an open concept, encouraging creativity and development of skills needed for problem solving.

Keywords: *Education, problem solving, creativity, curriculum, knowledge technologies*

INTRODUCTION

Nowadays, professionals in science and all sectors of industry are faced with overwhelming amounts of information. The information volumes relevant for a particular field grow perpetually in an exponential manner. At the same time, our society is facing many complex problems which require up-to-date knowledge from different disciplines to be taken into account, while available time and resources for solving problems are often limited. Consequently, one of the most important challenges, not only for scientists, but also for engineers, business managers and students, is the effective retrieval and use of information for valuable knowledge discovery.

It is therefore very important to teach the students – future scientists, engineers or managers – how to deal with huge amounts of knowledge available on-line, how to find a way to useful fragments of knowledge, how to connect them and use them to solve the problems (Burns, 2006). In education system, the prevailing emphasis is on mastering well-defined corpus of knowledge, while teaching students how to acquire newly developed and dispersed knowledge by themselves is often neglected. In general, schools also don't teach students about knowledge technologies which could support them in this process (Urbančič, 2007).

In this paper we discuss why and how education programmes could improve the situation. We also present how students' creativity and their ability of recognising, formulating and solving problems is developed in the Engineering and Management study programme at the

University of Nova Gorica. Further, we present a novel tool which enables to link knowledge from different fields. This tool has already proved to be useful in research work and may help students in their project work and thesis preparation in the future.

CREATIVITY THROUGH CONNECTIONS ACROSS CONTEXTS

To find creative and innovative solutions, it is important to connect not only facts and information from different contexts, but also different ways of thinking and problem solving. Several studies can be found in literature confirming the relevance of this ability. They include associations across different contexts, named bisociations (Koestler, 1964), examples of engineering inventions inspired by non-technical sources of ideas (Ferguson, 1994) and a study confirming that people connected across groups are more likely to express their ideas (Burt, 2004).

BISOCIATIONS

Information that is related across different contexts is difficult to identify with conventional associative approaches. The context-crossing associations, however, are the ones often needed for innovative discoveries. Such associations are called bisociations (Koestler, 1964). According to Koestler theory, a bisociation connects two concepts from commonly unrelated domains by observing them from a particular, innovative point of view. Bisociations have the potential of generating new discoveries, by enabling the entirely new cross-disciplinary connections among concepts from those contexts that are normally considered as distinct categories. Besides scientific discovery, the bisociations can enhance also the humour creation techniques and inspire the artists to create original works of music, theatre and art (Koestler, 1964).

Mednick (Mednick, 1962) defined creative thinking as the ability to generate new combinations of distant associative elements (e.g., words). He explained that thinking of concepts, which are not strictly related to the elements under research, inspires unexpected useful connections between elements and thus considerably improves a creative process. Actually, marginal observations are not necessarily characterized by mistakes or inaccuracies but may provide an indication of valuable information (Barnett and Lewis, 1994). From this point of view, creative thinking constantly involves a process of evoking latent possibilities to discover new useful information and unforeseen knowledge.

COMBINING DIFFERENT WAYS OF THINKING

Engineering is nowadays generally treated as derived from science. This assumption, however, ignores many nonscientific decisions, made by technologists as they design the world we inhabit (Ferguson, 1994). The emphasis is given to knowledge that can be expressed as mathematical relationships. Increasing computer power and improved models enabled for quick analyses. The computers apparent precision can give engineers an unwarranted confidence in the validity of the resulting numbers. Many modern schools produce graduates who are not fully aware of the myriad subtle ways in which the real world differs from the mathematical world taught in classrooms. Such engineering education may result in a shock to students when they discover that their decisions can not be based solely on mathematical calculations (Ferguson, 1994). Nonverbal expert knowledge can not be fully acquired during the studies, but it is essential to show the students the importance of such knowledge.

CONNECTIONS ACROSS GROUPS

Burns's (Burns, 2004) hypothesis is that people who are connected across groups are more likely to have good ideas. Namely, the behavior are more homogeneous within then between groups, so people connected across groups are more familiar with alternative ways of thinking and behaving, which gives them more options to select and synthesize from alternatives. Ideas come from a variety of paths from a variety of sources and often ideas are generated by moving knowledge from one group to another, or combining knowledge across groups.

Brokerage between industries, technologies or markets can be successfully used by companies. A company with clients in diverse industries may use technological solutions from one industry to solve client issues in other industries, where the solutions are rare or unknown. For example, as discussed in (Burns, 2004), the Hewlett-Packard company policy was to move engineers between projects. The result was that HP technologies were constantly mixed in new combinations. Similar results are available across organizations: higher company performance is reported when top managers have boundary-spanning relationships beyond their firm and beyond their industry. Brokerage may be considered as a capital and even venture-capital firms, spanning structural holes by linking co-investors not otherwise investing together, are reported (Burns, 2004).

PUTTING FRAGMENTS OF KNOWLEDGE INTO A BIGGER PICTURE

The process of identifying appropriate pieces of knowledge and putting them together to solve a problem at hand can be supported by several knowledge technologies. These include text mining (Feldman, 2006) and construction of ontologies (Joshi and Undercoffer, 2004). Here, we concentrate on a novel literature mining method RaJoLink (Petrič et el., 2009) which supports "finding the seeds of future discoveries in nowadays literature" (Urbančič et al., 2009) by suggesting candidate hypotheses and possible ways towards supporting evidence for these hypotheses.

RAJOLINK METHOD

The RaJoLink method was designed and implemented at the University of Nova Gorica by Petrič et al. (2009). It is based on Swanson's model of knowledge discovery (Swanson, 1990). Swanson regards scientific articles as clusters of somewhat independent sets of literatures, where common matters are considered within each set. He calls non-interactive those literatures that do not cite one another, that have no articles in common, and that are not cited at the same time by other papers. According to his proposal, such distinct unrelated literatures could be linked to each other by arguments that they treat. Consequently, if two literatures can be logically related by arguments that each of them addresses the unobserved connections between them represent potential sources of new knowledge. For instance, if literature *A* (i.e. a set of all available records about *a* in the database serving as a source of data) reports about term *a* being in association with term *b*, and another literature *C* associates term *c* with term *b*, we can thus assume literature *B* to be an unintended implicit potential connection between literatures *A* and *C*.

The RaJoLink method involves three principal steps, *Ra*, *Jo* and *Link*, which have been named after the key elements of each step: searching for rare terms, joint terms and linking terms. The three steps are presented as procedures of the RaJoLink method in Figure 1.

In step *Ra*, the literature about phenomenon *c* (i.e. the domain under investigation) is examined. The aim of this step is text analysis of the literature about phenomenon *c* in order to identify interesting terms that rarely appear in literature C, (i.e. the documents about phenomenon *c)*. In step *Jo*, separate sets of documents about the selected rare terms are inspected and interesting joint terms that appear in the intersection of these sets of documents about rare terms are examined. At least one of them is then selected as the candidate for *a*. The relationship between phenomenon *c* under investigation and a candidate joint term *a* represents the hypothesis generated in the open discovery part of the RaJoLink method. In step *Link*, which implements the closed discovery, linking terms *b* that bridge the gap between the domain *A* and the domain *C* are searched for. Relations between literature *A* and literature *C* are established with pairs of documents that contain *AB* and *BC* relations. Finally, the user has to evaluate the *AB*, *BC* pairs of documents in support of the generated hypotheses about the relation between the domain *A* and the domain *C*.

The method is implemented as a user-friendly computer program which has been used as a tool supporting researchers in their process of searching for new connections between concepts in biomedicine (Petrič et al., 2009; Urbančič, 2007).

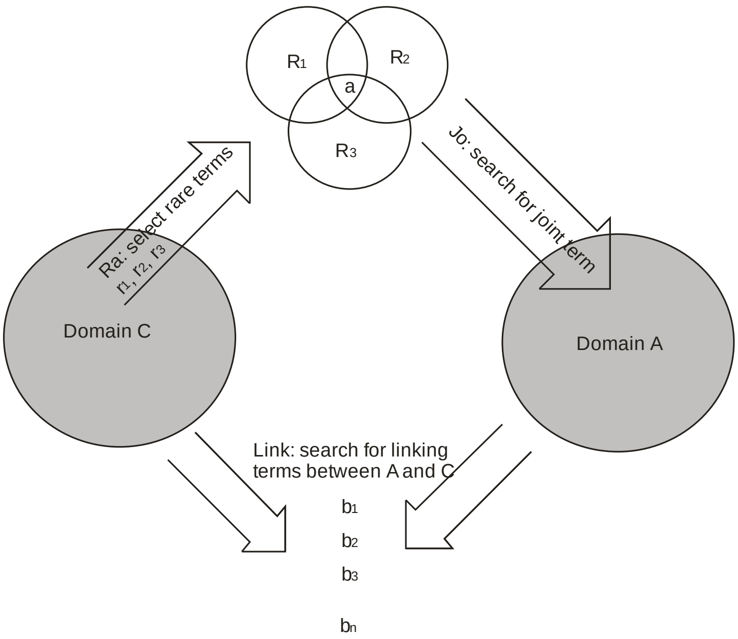

Figure 1: Procedures of the RaJoLink method.

HOLISTIC APPROACH

In solving problems in real life, people often collect ideas and information and put them together. But in many cases it is difficult to say when the picture is complete while reliable information regarding the whole picture is missing. The ability to recognise the whole is crucial not only for successful problem solving but also for successful problem definition. Actually, problem definition is the most difficult thing to teach (Burns and Jordan, 2006).

The holistic system thinking is the way to see the whole system (Burns and Jordan, 2006). Science and engineering fields incorporate holistic thinking as a natural part of students' development. Some fields explicitly teach modelling skills by starting at simple models and then adding variables successively to increase the explanatory capability of the model. Business problems, on the other hand, are more difficult since they do not have clearly defined boundaries, components and interactions in the models. These skills can be developed by special techniques, including case studies, simulations, learning by doing and gaining experience under supervision.

IMPLICATIONS FOR EDUCATION

In engineering study programmes, the prevailing emphasis is on engineering knowledge and skills. Besides highly specialized individuals, industry and other employers need also professionals with capabilities of connecting technological, economical and organizational aspects needed for success of an enterprise. It is a big advantage for engineers to understand the connection between technical solutions and their economic aspects, and also to be prepared to work in interdisciplinary teams (Gider and Urbančič, 2010). One of the study programmes preparing students for this kind of jobs is also Engineering and Management at the University of Nova Gorica. Lack of this profile may be indicated by the fact that employability of graduates at this programme in one year after graduation is over 95%.

While preparing the curricula, especially for post graduate students, special attention was paid to developing their ability for problem definition and problem solving. The profile itself is defined as interdisciplinary. The basic knowledge from different fields should give students solid background for connecting information across contexts. As the programme is spanning over technology and management, the combination of these two fields comprises two rather different ways of thinking: while technology favoures analytical approach, the decisions in management are not based only on analytic methods, but also to a great deal on intuition and experience. Taking this starting position into account, we wanted to include issues such as how to see a problem as a whole, how to actually find knowledge relevant for a given problem, and how to use it for problem solving. The best way to teach such skills is gaining experience under supervision (Burns and Jordan, 2006). In light of the view that developing skills for team work and open problem solving without direct instructions should be supported throughout education at all levels (Gider and Urbančič, 2010), student project work was introduced to the programme.

STUDENT PROJECTS

The curriculum of master's programme Engineering and Management includes

- "team project", held in the first year and
- "individual project" in the second year.

The students' work and progress is in all stages supervised by the project coordinator and in the case of individual project also by the individual supervisor. The projects were launched in the 2006/2007 (team) and 2007/2008 (individual) academic year.

Team project

The idea of the team project is to give the students opportunity to gain experience with an extensive project where different skills are needed, e.g. team work, coordination of work, project management, research, problem solving, public presentations, time management etc. The course gives the students hands-on experience of the work on a project which is very close to the reality, thus developing several important skills that cannot be obtained through the usual »ex cathedra« learning style. Students are forced to gain the experience in team work, and to overcome the uncertainties and obstacles which arise in such projects (Gider and Urbančič 2010). The project encompasses generating ideas as well as validation of these ideas from different points of view (technological, economical, social etc.). In this way students also learn that single problem may be seen in various ways.

Individual project

The individual project introduces the concept and methodology of scientific research to the students. As a firs step, students are expected to search for valuable information by themselves. In this way, they not only improve their knowledge and skills in the project-specific area, but also learn about general approaches to problem solving. The emphasis is not solely on gathering and connecting information to get new ideas (Figure 2), but also on their ability to see the problem as a whole. Only by having the whole picture in their mind, they can search for the missing parts. Creating a complete frame of a given realistic problem is a rather complex and complicated task, therefore each student works under supervision of a specialist for the field in question.

The projects are typically interdisciplinary and students are encouraged to find and define the problems. Especially students with work experience prefer searching for problems to solving pre-defined problems. In this way, benefits are multiple: for the student who gains experience in problem solving, for the companies which get solutions of their problems, and also for the university which gets valuable information regarding existing "real world" problems.

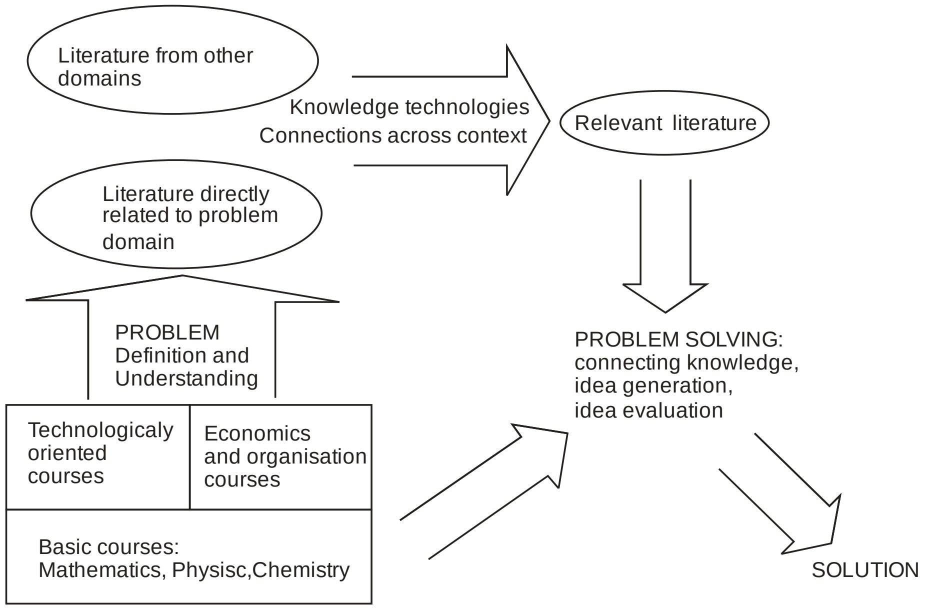

Figure 2: Connecting knowledge to solve complex problem during students work in individual project.

ANALYSIS OF INDIVIDUAL PROJECTS

During the last three years 38 students took the subject and 33 final reports were analysed. 21 projects were based on concrete problems from companies, while the remaining 12 were more general. From 33 accomplished works, in 20 cases the theme was proposed by the student. From the rest 5 students, who have not yet finished their work, only 1 theme was proposed by the student. This reflects that students with higher initiative are also more successful.

Table 1. Number of papers spanning over different fields.

	Management	Product & tech.	Energy	Quality	Environment	IT & optimisation	web	No. of papers from this field	No. of papers connecting this field with any other field
Management	4	5	1	2		1	1	14	10
Product & technology	5	5	1		3	1	2	17	12
Enerergy	1	1			4			6	6
Quality	2							2	2
Environment		3	4			1		8	8
IT & optimization	1	1			1	1	1	5	4
Web	1	2				1		4	4

By analysing all texts, several common key words were found: management, technology, energy, quality, environment, information technology, optimisation methods and web. 24 projects spanned over at least two fields. Interactions are presented in Table1. Numbers on diagonal present papers which include only one field. In 3 cases students have linked three of these fields. The last two columns give the numbers of papers where the field is included and the number of papers where it is combined with at least one of the others.

When evaluating creativity we have followed the Mednick (Mednick, 1962) definition of creative thinking, i.e. creativity is the ability to generate new combinations of distant associative elements, only to a limited extend. At this stage of study, we prefer to grade the ability of students to define and to solve the problem on their own. 20 out of 33 students were able to detect and define the problem alone based on their knowledge and observations. In solving the problem, however, the help of supervisor was crucial for almost all students. If we rank the creativity form 1 to 5 (1: no student initiative, 2: knowledge collection with no added value 3: conclusions selected from knowledge collection 4: student is able to find new solutions with suggestions, 5: student was able to give new combinations), the average value is 3,4. This shows that the majority of students are able to apply existing solutions of similar problems to solve their own problem, but they did not exhibit higher levels of creativity.

We also examined students ability of finding relevant literature. Here, again, students were ranked 1 to 5 (1: inadequate literature, 2: mainly web literature, 3: web with basic books, 4: web, books and basic papers, 5: up to date papers and books). The average value of 3,1 reflect the problem that students rely mainly on web resources while they do not search for up to date research papers.

The experiences with the project work so far are encouraging, however, there is still room for improvement. Based on the presented analysis, the weakest point at this stage is the phase of knowledge discovery. During this time, the RaJoLink method was developed and tested in non-trivial biomedical domains (Urbančič et al., 2007, Urbančič et al., 2009) to an extent which allows it to be recommended to students as a useful tool. Also, more emphasis should be put on the ability of holistic thinking. Since it has been observed that students with higher initiative have been more successful, we will more consistently encourage their initiative.

CONCLUSION

In our complex world, it is sometimes a great challenge to find the right knowledge or technology to solve a given problem. In overcoming the difficulties related to this problem, knowledge technologies can serve as a very useful tool. We believe that similarly as learning computer skills started its way to education at all kinds and levels a couple of decades ago to become generally accessible and assumed knowledge for everybody nowadays, learning knowledge technologies will find their way in schools in the forthcoming years.

In the Engineering and Management study programme at the University of Nova Gorica, there is a strong emphasis on interdisciplinarity and creativity. Therefore, courses from different fields which also stimulate different ways of thinking are included in the curriculum. During their project work students practise connecting knowledge from different fields and resources to solve a given problem under supervision. We believe that this kind of training helps the students in their further careers.

ABSTRACT

This paper focuses on the importance of starting science and technology education at a young age and at the consequential importance of providing primary school teachers with enough professional background to be able to effectively incorporate science and technology into their teaching. We will discuss a large-scale program in The Netherlands that is aimed at the professionalization of elementary school teachers in the field of science and technology. Theoretical and practical considerations will be provided for the three pillars that ideally should be included in teacher training programs in this domain: (1) Primary school teachers' knowledge of and competency in scientific concepts and scientific reasoning; (2) Primary school teachers' attitude towards science (in terms of cognitive, affective, and behavioural dimensions of attitude); and (3) Primary school teachers' pedagogical competency to enhance inquiry-based learning.

Keywords: *S & T teacher education; Primary school teachers; Policy initiative; Teacher professionalization.*

INTRODUCTION

Despite the fact that in society today, we are becoming increasingly dependent upon science and technology on a number of fronts, much of the population has little scientific or technological knowledge and the image of a professional career in the natural sciences and technology is not very positive. Although various measures have been undertaken to attract more students in science and technology studies, the interest in these disciplines has declined further among young people over the past decade (de Grip & Smits, 2007). While this lack of interest in science and technology often only manifests itself when young people must choose their high school study subjects, most students have already excluded the choice of a science or technology study long before this, during their elementary school period (Tai, Liu, Maltese, & Fan, 2006; Walma van der Molen, 2008).

How could this be remedied? In the Netherlands, a large scale project called the VTB Program (Broadening Technical Education in Primary Education) is designed to help primary schools integrate science and technology into their teaching. During a three-year period, schools receive financial, organizational and subject-specific support to put this into practice. By the end of 2010, 2,500 primary schools (one third of the total number) will have embedded science and technology in their education with support from the VTB program and regional support desks. The knowledge, expertise and experience developed and acquired by VTB schools will be made available to all primary schools in the Netherlands (see: http://www.vtbprogramma.nl/home/over-vtb/about-programme-vtb.html).

Although initiatives such as the VTB program have been reasonably effective, particularly where children's joy for science and technology projects is concerned, a major problem that cannot be solved simply by allocating more time to science and technology in primary education, is the fact that primary school teachers are not sufficiently trained to teach science and technology. International research (e.g., Palmer, 2004; Trumper, 1998) shows primary teachers' knowledge of science and technology and their attitudes towards science and technology to be generally low. Many elementary school teachers do not feel sufficiently prepared to teach science and technology, find it difficult to deal with the questions of students in this area, and rather fall back on highly structured text books (Skamp, 1991; Yates & Goodrum, 1990). Such practices lead to less than positive attitudes towards science and technology on the part of elementary school children, and to lower science and technology achievement (Harlen & Holroyd, 1997; Jarvis, 2004). There is, nevertheless a glimmer of hope. Research shows, for example, that when teachers are given greater knowledge, skills, confidence, and a more positive attitude via continuing education efforts, they subsequently teach science and technology in a better manner and can improve the knowledge, skills, and attitudes of their students in this area (e.g., Osborne, 2003; Osborne & Dillon, 2008).

The situation sketched above has led the Science and Technology Platform in the Netherlands to launch another large-scale program that is aimed at the professionalization of elementary school teachers in the field of science and technology (VTB-Professional or VTB-Pro program). The development of teachers stands central in this program, which offers a minimum of 5000 current and 5000 aspiring elementary school teachers a special training trajectory within the field of science and technology. The training program addresses three pillars of science and technology education: (1) Development of knowledge of key science and technology concepts in addition to key science and technology skills; (2) Development of more favourable attitudes towards science and technology; and (3) Development of the instructional skills needed to stimulate inquiry-based learning and learning by technical design.

The basic assumption within the program is that in order to genuinely and confidently address science and technology topics and projects within their everyday class situation, elementary teachers must first develop their own knowledge, attitudes, and inquiry skills within the field of science and technology in an open, exploratory, and reflective manner. The expectation is that when the teacher or aspiring teacher him/herself acquires greater knowledge, research skills, meta-cognitive skills, positive values, and confidence, he or she will also be in a position to provide more challenging, stimulating, inquiry-based instruction to his/her students.

For this purpose, it is important that the training offered to teachers be challenging, provides stimulating experiences, and devotes considerable attention to not only substantive knowledge within the field of science and technology but also to the image of science and technology, philosophical issues within the field of science and technology, a more positive attitude towards science and technology, and the promotion of one's own inquiry-based learning. The aim is to have the teacher and aspiring teacher participate in the learning process and learn to think, judge, decide, and act independently within the broad field of science and technology. In addition to this, attention must be paid to the embedding of science and technology in social and practical contexts.

This paper will discuss a number of theoretical assumptions that are argued to be of critical importance for the aforementioned professionalization of teachers. This will be done in terms of recent research in the areas of science education and attitude formation in addition to recent insights regarding inquiry-based learning and learning by design (i.e., constructivist learning). The specific theoretical assumptions will be complemented with different examples of potential implementations for the teacher training programs. The concepts will be considered in three separate sections of the paper that reflect the three pillars that are fundamental to the VTB-Pro program.

KNOWLEDGE AND SKILLS WITH RESPECT TO SCIENCE AND TECHNOLOGY

In order to identify the knowledge and skills for teachers to acquire, a clear view must first be attained of what can be understood under science or science and technology. In a recent report from the European Commission ("Science Education Now: A Renewed Pedagogy for the Future of Europe," which is better known as the Rocard Report, 2007), both the natural sciences and technology are described as systems of knowledge that attempt to model objective reality. For the current discussion, the preceding has been translated as follows:

> Natural science and technology are ways to acquire and apply knowledge on the basis of not only the methods of natural science and technology but also the structured whole of knowledge and skills resulting from this.

Of fundamental importance for the substantive description of the knowledge and skills that are of specific relevance for science and technology education, is recognition of the fact that a dichotomy characterizes the field: on the one hand, there is the *knowledge* of *concepts*; on the other hand, there is the *manner* in which such knowledge is acquired. For technology, one can also speak of the additional use of knowledge for design and manufacturing purposes.

The aforementioned dichotomy has also been described in various other publications (e.g., Harlen, 1999; OECD/PISA, 2006). Some publications refer to knowledge *of* science and technology as opposed to knowledge *about* science and technology, while other publications refer to knowledge of scientific and technological concepts as opposed to knowledge of scientific and technological process skills. Of particular importance, however, is that these elements *together* constitute a system of knowledge and skills within the field of science and technology, and that the elements should be considered in conjunction with each other for the professionalization of teachers and aspiring teachers. In the following, the elements will be considered further.

Knowledge of concepts

It is not easy to describe the key knowledge components within the field of science and technology unambiguously. In the OECD/PISA study, "knowledge of science" was divided into four categories: knowledge of natural science systems, knowledge of living systems, knowledge of the earth and space systems, and knowledge of technical systems. The descriptions presented in the study itself come mostly, however, from a natural science perspective and encompass very few contexts of relevance for young children and their teachers.

Nonetheless, the PISA classification — which goes back to the "Science Standards" from the USA in 1996 — allows us to formulate some critical concepts more precisely. The four initial systems can also be expanded to include a fifth category, namely mathematical systems. And the different categories (i.e., systems) can next be characterized in terms of the concepts indicated below.

Physical systems*.* Where attention is devoted to concepts such as: 1) features of objects (whether natural or constructed); 2) position and movement of an object in space and time; 3) force and motion; 4) energy or the capacity to cause change; 5) transformation of energy; 6) radiation, such as light, warmth, radio frequencies, x-rays; or 7) electricity and magnetism.

Living systems. Where attention is devoted to concepts such as: 1) the cell, organ, and organism; 2) man, plant, and animal; 3) respiration, circulation of blood, and digestion; 4) life cycle and reproduction.

Earth and space systems. Where attention is devoted to concepts such as: 1) the structure of the lithosphere, hydrosphere, and atmosphere; 2) the soil, mountains, stratification, change (erosion), and tectonics; 3) water, including the ocean, sea, lakes, rivers, canals, tide; 4) air, including the atmosphere and stratosphere; 5) climate and weather; 6) history in the form of fossils; 7) the earth *in* space including the structure of space with respect to earth, moon, sun, and stars in particular; and 8) gravity.

Technical systems. Where attention is devoted to concepts such as: 1) construction, facilitation, and progress; 2) design, including criteria, limitations, innovation, invention, problem solving; 3) transformation of energy, function, materials; 4) facilitation of a better life and scientific progress including information and communication technologies, games, medical systems, traffic safety systems, and navigation tools and instruments among other things.

Mathematical systems. Where attention is devoted to concepts such as: 1) quantities, including numerical phenomena, quantitative relations and patterns, "number sense", and logical operations; 2) form and space including spatial orientation, navigation, representation, forms, and figures; 3) changes and relations including correlations, diagrams, tables, types of change (e.g., linear or constant); and 4) uncertainty, data, and chance.

When considering these knowledge concepts, it is important that considerable attention be paid to the cross-connections between these systems in the composition of the teacher-training program. Structural knowledge of concepts from different domains only emerges when individuals learn how two or more concepts relate to each other and how different systems occur within certain themes. In addition, special attention should be paid to how the mathematical system appears in all of the other systems.

In the application of the mathematical concept of quantity, it is important — for example — to see that important aspects of this concept, such as an understanding of relative size and the recognition of patterns in data, occur in virtually every branch of science and technology. *Patterns* occur and can thus be detected in language, music, video, traffic, buildings, art, and nature. The concept of "form and space" can be seen in the *forms* that are visible all around us: houses, bridges, snowflakes, maps, crystals, shells, plants, and the universe. The mathematical concept of "changes and relations" points to the fact that every natural phenomenon is, in fact, the manifestation of a change and that innumerable examples of relations between phenomena can be perceived in the world around us. Organisms grow; change can be continuously perceived in the seasons, the tide, and the weather; there is development in the quickness of computers and air pollution; and much, much more. To close, it is important to emphasize that the mathematical concept of "uncertainty" also appears, in fact, in all of the scientific and technological disciplines. Scientific and technical knowledge is always the product of a process in which uncertainty (i.e., chance) cannot be excluded: Bridges collapse, the weather is often different than expected, air pollution is worse than predicted, and unjust convictions sometimes occur on the basis of unreliable data.

The aforementioned illustration highlights the importance of not only emphasizing the cross-connections between concepts in the teaching of scientific and technical concepts, but also taking the *relevance* of what is learned as the starting point for the supplemental training of teachers. Given that many teachers (and their students) are not familiar with many technical and scientific concepts, this gap must be bridged via the connection of abstract concepts to *clearly recognizable and relevant contexts*. Relevance can be found in the personal sphere, daily professional practice, the neighborhood, society, or — for instance — further study. With the use of clearly recognizable contexts, it can also be made clear that one and the same concept can play a role in widely differing contexts and systems (Waarlo, 2007). By making these connections and any changes of meaning explicit, the transfer of conceptual knowledge can be expanded and comprehensive knowledge within the broad domain of science and technology can emerge.

Scientific process skills
Within the domain of science and technology skills, the scientific method stands central. The following elements play a critical role in the scientific method: asking the right question (i.e., a scientific question born out of curiosity), sufficient justification of one's question, identification of relevant information, design and conduct of experiments, measurement including insight into the degree of uncertainty in the data, and critical evaluation of the results. In addition, hypotheses, logical reasoning, and critical reflection play an essential role. Stated concretely and based on Harlen (1999), the following can be understood as critical science skills:

- **observation**: a fundamental skill that allows people to select information via the use of all senses;
- **drawing of space-time relations**: learning to judge how much time an event takes and the volume or area that an object occupies;
- **classification**: recognition, identification, sorting, and ordering according to similarity or difference;
- **hypothesis formation**: on the basis of consistent, general information from observations and other data, explication of those assumptions that can possibly explain a given occurrence or observation;
- **prediction**: the formulation of the results of a study in advance (i.e., on the basis of a given hypothesis);
- **experimentation**: the testing of hypotheses via actual research using carefully controlled circumstances and methods;
- **manipulation and control**: the imposition of systematic conditions and determination of whether these produce the intended effect or not;
- **measurement**: determination of sizes, time, areas, speed, weights, temperature, volume, etc.;
- **analysis**: the distinction of meaningful (i.e., systematic) information from noise and insignificant artifacts;
- **conclusions**: the drawing of conclusions on the basis of all the observations and data collected in order to evaluate the hypotheses put forth;
- **interpretation**: attempts to understand the data collected and connect the conclusions drawn on the basis of this data to other data and ideas;
- **communication and dissemination**: one should be able to present that which was discovered or observed in a powerful manner using various media.

Technical process skills
Under technical skills, one can think of practical reasoning that occurs in addition to theoretical reasoning. Practical reasoning entails the capacity to reason means-ends

relations and the relations between the functions of a planned construction (i.e., artifact) and its physical realization or structure. These forms of reasoning constitute the components of the technical process of designing in which the skill of visualization also plays an important role. Just as for many scientific skills, technical skill is the ability to model reality and use physical models for this purpose.

The aforementioned skills — in conjunction with knowledge of the relevant concepts — should be included as a whole in the professionalization of elementary school teachers. In keeping with this, it is relevant that attention be paid to the philosophy of science and technology. Aspects of particular importance are: 1) recognition that the different sciences constitute “lenses” that can be used to view reality and 2) recognition that there are, for this reason, different sciences: such as, the social sciences, the liberal arts, and the natural sciences, which differ methodologically from each other. The philosophy of technology concerns predominantly the conceptualization of artifacts (i.e., manmade items), technical functions in contrast to biological functions, and the normative component of technological knowledge (i.e., prescriptive knowledge (de Vries, 2005). The interaction between technological and societal developments is also an important theme here.

ATTITUDES TOWARDS SCIENCE AND TECHNOLOGY

In the relevant research literature, the concept of “attitude” is construed as an internal, personal, psychological tendency to evaluate a particular object or construct in a positive or negative manner (Eagly & Chaiken, 1993). This personal tendency can persist for a longer or shorter period of time and involves cognitive, affective, and behavioral components. The *cognitive* component of the concept of attitude consists of *thoughts or opinions* about a particular object or construct. The *affective* component consists of *feelings and moods* with respect to a particular object or construct. The *behavioral* component consists of *actual behavior or the intention to do something or avoid doing something* with respect to the object of the attitude. In such a manner, a positive attitude with respect to learning or studying can consist of thoughts or opinions about the importance of learning for the attainment of a good job or a good future, personal feelings of pleasure derived from learning, or actual behavior in the form of studying hard or the intention to undertake a particular study.

Within the field of social psychology, attitude is traditionally seen to be one of the most important motives behind numerous processes and clearly related to motivation and interest. In keeping with this, attention to the notion of attitude in the literature on science education has strongly increased over the past few years. Critical in this regard, however, is the distinction between a scientific attitude and attitudes towards science (see Osborne, 2003). A scientific attitude manifests itself in the form of scientific thinking: curiosity, creativity, perseverance, critical reflection, and so forth. Such a scientific attitude was described in the outline of the necessary scientific process skills (see previous paragraph) and will also be considered in the section on inquiry-based learning below.

A different set of thoughts, values, feelings, and behaviors can be understood under attitudes *towards* science and technology — thoughts, values, feelings, and behaviors that address — for instance — one’s thoughts about the level of difficulty characteristic of the sciences and technology, the value attached to science and technology for society, feelings of pleasure or interest with regard to science and technology, and the desire or intention to learn more about science and technology. Considerable international research has shown that elementary school teachers often have little scientific and technological knowledge, and in addition have quite negative attitudes towards the natural sciences and technology (e.g., Palmer, 2004). These teachers do not like science and technology subjects and they hold low estimates of their capacity to teach these subjects, which often relates to negative experiences during their own elementary or high school education (Tosun, 2000). Such a negative attitude can lead teachers to devote less time to science and technology and may make it difficult to stimulate the knowledge, skills, and positive attitude of their pupils within the field of science and technology.

The situation described above is unfortunate, and it is important that the self-esteem, interest, and enthusiasm of teachers in science and technology be stimulated and supported. Research shows that such an endeavor can have a positive effect, not only on the teachers themselves, but also on the knowledge level and attitudes of elementary school students towards science and technology (e.g., Jarvis, 2004; Palmer, 2004). In addition to an integrated offering of knowledge and skills within the domain of science and technology and in addition to more insights in inquiry-based learning (which will be discussed in more detail in the next section), a very important (and often overlooked) element of the professionalization of elementary school teachers should thus be the explicit focus on teachers' own attitudes towards science and technology. It is important that teachers and aspiring teachers be aware of their own thoughts, values, feelings, and behavior in the field of science and technology. Such an awareness may be stimulated within teacher-training by paying explicit attention to the cognitive, affective, and behavioral dimensions of attitude, through:

- **discussion** (e.g., of the breadth and historical significance of science and technology within society)
- **reflection** (e.g., upon one's own elementary and high school education history within the domains of science and technology and a prior tendency to avoid learning or education in these domains)
- **training** (e.g., to provide new and positive experiences with regard to science and technology in order to increase teachers' pleasure and self confidence in the domain of science and technology)
- **lectures** (e.g., in which attention is paid to gender differences, stereotyped images of science and technology, and the lack of positive role models in science and technology for girls in particular)

PEDAGOGICAL SKILLS FOR INQUIRY-BASED LEARNING AND LEANING BY DESIGN

Science and technology education have their roots in Victorian England (1850-1900) where agrarian society made way for a society based on scientific and technological expertise. This new society could only be sustained with the training of people in science and technology. Disagreement existed, however, with regard to the exact nature of this education and, since that time, the form and content of science and technology education have regularly been the topic of debate. In the Victorian era, people were of the opinion that science education should be part of the education received in primary school. At that time, it was believed that such an education should be presented as "the science of everyday things" and thus aimed at the observation of nature: botany, zoology, physiology, and so forth. This perspective was concerned mainly with the establishment of knowledge and an understanding of the basic principles of natural science. Early in 1900, an alternative view of science education emerged. Thomas Huxley (1918, in: Osborne & Hennessy, 2003) viewed science education as predominantly a means for intellectual development. For Huxley, it was not so much the content of a particular science that was of significance but, rather, the unique capacity of science in general to train one's intellect.

Such discussions — of the importance of acquiring scientific content knowledge as opposed to mastery of the scientific thinking process — still occur today. Much of science and technology education in primary schools today, however, is still aimed primarily at the acquisition of so-called scientific literacy via the transfer of factual knowledge. Knowledge is seen to be a product of instruction, and the assumption is that having such knowledge will lead to a greater interest in and adoption of the values of science and technology. Research, however, has shown that the transfer of scientific and technological knowledge alone is not sufficient for the creation of a broader understanding of science and technology (Zint, 2002). During the past few years, we therefore see a renewed international plea for science and technology education that not only devotes attention to conceptual knowledge, but also promotes inquiry-based learning. This form of learning draws upon social-constructivist ideas about learning in which: knowledge is construed as a construct as opposed to a product, the learner him/herself must experience things, both context and social relevance are of importance, and a scientific attitude is developed.

It should be noted, however, that this inquiry-based learning often functions as ‘a magic word’ and that all kinds of projects within the context of “hands-on science” are considered as inquiry-based learning. As some authors have recently shown, this qualification is not always justified (e.g., van Graft & Kemmers, 2005; Rudolph, 2005). Children are challenged in most “hands-on” science projects primarily to work together on, for example, the building of a construction. Although such projects can realize a number of important objectives for science and technology education (e.g., collaboration, responsibility, reflection, observation, prediction, generalization), the fact that science is more about the construction of ideas than the construction of objects or machines is missed in these projects (Rudolph, 2005).

For the implementation of actual inquiry-based learning, it is thus important that not only “hands-on” but also “minds-on” science activities be undertaken and that inquiry-based learning be distinguished from learning to inquire (van Graft & Kemmers, 2005). Having students (children ánd adults) learn to do research and acquire the knowledge and skills relevant to the scientific method is generally understood under learning to inquire. For inquiry-based learning, in contrast, students must undertake an inquiry (i.e., research) to learn about *something else*. For inquiry-based learning, the conduct of research is a means; for learning to inquire, the conduct of research is an end.

In the field of science and technology, learning by design can be seen to play a role in addition to inquiry-based learning. Once again, the notion goes further than the aforementioned construction of an object or machine. By thinking more or less systematically about how the environment can be adapted to meet the needs and desires of people, children learn to think about not only the existing reality but also about other possible realities. Used in combination with the scientific method, learning by design is a manner to stimulate creativity. Just as inquiry-based learning, learning by design is a question of both “hands-on” and “minds-on” learning.

For the application of all of the above, the professionalism of teachers in the field of science and technology must be strengthened along two fronts. First, the *generic level* of knowledge and skills on the part of teachers must be strengthened by having them become more comfortable in the world of doing research in science and technology. This boils down to greater attention being paid within all disciplines to understanding the necessary concepts, the conduct of practice-based research, and the guidance of student research.

The second front for improvement is to strengthen the *specific competencies* of teachers for the guidance of student research within the field of science and technology. In fact, student research encompasses both inquiry-based learning and learning to inquire. And for teachers, this means learning to create a challenging learning environment and respond to the inquisitive questions of children in such a manner that their curiosity is satisfied and further stimulated.

The best way to teach teachers this is via “learning by doing.” In such a manner, they *themselves* actually experience what the empirical and regulatory cycle of production and application really means and how one can operate with regard to this. In such a manner, they also learn to adopt a scientific attitude in which curiosity, perseverance, appreciation of originality, creativity, responsibility, productive critique (including self-critique), and the adoption of an independent stance in one's thinking all play an important role.

When teachers have developed in such a manner, they can also develop the competence needed to impart science and technology concepts, skills and attitudes to their students in an inquiry-based manner. They can do this by having students look, listen, touch, smell, and taste (i.e., observe); encouraging them to ask more questions; having them try to predict what will happen; having them collect and use information from different sources that can range from rocks, sticks, and beetles to numbers, tables, and diagrams; stimulating them to seek and apply creative new applications for particular constructs; having them talk about their experiences and ideas using their own words; and having them examine those patterns that stand out in observations and measurements (Murphy, 2003).

For the aforementioned developments to occur, it is of importance that considerable attention be paid to *reflection* during the professional development of teachers. This includes not only personal reflection (e.g., Who am I? What are my capacities in the field of science and technology? What do I want to achieve in the field of science and technology?), but also reflection upon the learning process (e.g., What have I learned? How did I learn this? How can I apply what I have learned to my own teaching situation?). Such forms of reflection have the important objective of *empowerment* for teachers and aspiring teachers. In addition to enhanced self-confidence and instrumental professionalism within the domain of science and technology, such reflection increases the probability that teachers will continue to learn in a self-guided manner and stimulate colleagues to do the same.

DISCUSSION

In the above, a description was provided of the qualities that teachers and aspiring teachers should have for elementary science and technology education. It was argued that teachers should acquire knowledge of important science and technology concepts *and* the skills needed to gather such knowledge. It was also argued that a positive attitude towards science and technology is essential, and that the cognitive, affective, and behavioral aspects of such an attitude should be explicitly discussed and reflected upon during teacher-training. Last, it was contended that the most important didactic instrument to present science and technology in an inspirational manner is to foster inquiry-based learning and learning by design.

While these three pillars of science and technology education were discussed in three separate sections, it should be clear that they are closely connected. For instance, the principles associated with the third component of science and technology education — namely, the stimulation of inquiry-based learning and the concomitant assumption that learning can occur via exploration, asking questions, and self-discovery — are closely associated with the inferential knowledge and skills required for the scientific process. The attitude component can be viewed as a more comprehensive component that relates to both other components of science and technology education. Starting from the assumption that the attitudes of people determine their actions, thoughts, feelings, and choices to at least some extent, it can be asserted that having a positive attitude towards science and technology is just as important as, for instance, having a positive attitude towards reading. One can indeed learn to technically read to a sufficient extent, but only when a positive attitude towards reading has developed will one also read at one's own initiative and increasingly more for one's own pleasure. The foundation for a high quality professionalization program in the field of elementary science and technology education can be laid with the incorporation of all the aforementioned pillars into the program and making the connections between the different components sufficiently transparent.

In closing, it should be emphasized that strengthening the competence of teachers in the field of science and technology education can also enhance the level of teacher functioning *in general*. At its core, working on "the teacher as researcher" has a much broader spectrum than just the domains of math, science, and technology. When teachers learn to treat their own amazement and that of their pupils in a more systematic manner, this can also have significance for the domains of language, reading and writing, or the social-emotional development of students. By jointly going through processes, such as from perception to concept formation, from concept formation to causal relations, from causal relations to prediction, and from prediction to evaluation, teachers can help their students with the systematic solution of practical problems in all sorts of domains. In such a manner, working on science and technology education can serve a more general objective, namely improvement of the level of the teaching profession as a whole.

ABSTRACT

The present paper presents two case studies from the larger design research that aims at producing research-based molecular modeling material to be used to increase junior high school students' interest to study chemistry. The main research questions were: (i) how interesting do students find working with computer-based molecular modeling and (ii) how does the developed material affect students' interest. Altogether 118 junior high school students participated in this study. Survey and semi-structured group interviews were used as research methods. According to the results, computer-based molecular modeling is one way to improve the attractiveness of chemistry among young students. The students found molecular modeling interesting because (i) it offered some variety to regular chemistry lessons, (ii) it helped to improve the understanding of chemistry, and (iii) the students themselves had an active role. Working with computer was also highly valued. Students found molecular modeling fun, interesting, useful, and inspiring via the new study material on the gases of the atmosphere, which was used in the study.

Keywords: *information communication technology (ICT), molecular modeling, interest, design research, chemistry, chemistry education, junior high school*

INTRODUCTION

There is a lack of interest in chemistry among junior high school students. For example, a PISA-study has shown that students are not very interested in studying chemistry (Arinen & Karjalainen, 2007). Interest can be defined as a phenomenon that arises when individuals interact with their surroundings (Krapp et al., 1992). Over time situational interest can develop into personal interest (Hidi & Andersson, 1992). Many previous researches have shown that students are interested in working with computers (e.g. Lavonen, 2005). Published studies have shown that teachers and students generally have a positive attitude toward molecular modeling (e.g. Aksela & Lundell, 2008).

In Finland, there is not enough research-based material to be used in computer–based molecular modeling at junior high school level (Aksela & Lundell, 2008). The main aim of the larger design research study (Edelson, 2002) is to create material for chemistry education that can be used to increase students' interest in chemistry.

MODELS AND MOLECULAR MODELING

One goal of chemistry education is to teach students how to use and interpret models in chemistry, and how to understand their nature (Gilbert et al., 2000). Models link the scientific theories to practice (Gilbert, 2005). Chemistry education should provide students with tools to create their own mental models of the phenomena. Students exploit scientific models while building up their own interpretations (Treagust et al., 2002).

Chemical models are used in chemical research and education as a tool to explain, describe, and predict chemical concepts, processes, and phenomena (Barak & Dori, 2000). There can be several models to describe one phenomenon from different perspectives. Therefore the students should understand that a certain model is only one way to represent the phenomenon or concept from a particular perspective (Treagust et al., 2002).

Computer-based molecular modeling is a useful and flexible tool for chemistry education. A computer offers a quick and easy way to employ visual models, which are used to support verbal presentations. It is possible to visualize, adapt, and change existing models with modern molecular modeling, and use these models in multifaceted chemistry education (Aksela & Lundell, 2008).

RESEARCH GOAL AND POPULATION

The two case studies in question are part of a larger design research, which aims at producing research-based molecular modeling material that is used to increase junior high school students' interest to study chemistry. The design research study includes three stages: (i) an empirical analysis on the needs to develop the material, (ii) a study on what kind of material should be developed, and (iii) a study on how the material affects the students' interest. The first and third parts of the design research are presented in this paper.

There are two main research questions for this study:

- How interesting do students find working with computer-based molecular modeling?
- How does the developed material affect students' interest?

This study concentrates only on students' interest towards computer–based molecular modeling as a tool in chemistry education. The respective influence on learning was not studied, and the gender of the respondents was omitted.

Altogether 118 junior high school students participated in the study. In the first case study (problem analysis, see Figure 1), the population was 60 high school students. In the second case study (material evaluation, see Figure 1), the number of participants was 58. The students had no previous experience in computer-based molecular modeling, and they came from different parts of Finland. The students were randomly selected from the groups that took part in molecular modeling lessons at the Gadolin chemistry laboratory, which is a free learning environment for schools that operates in the Department of Chemistry of the University of Helsinki.

The developed molecular modeling material for studying the gases of the atmosphere was used in the second case study. Modeling was used as a part of a historical frame story. Throughout the story of the history of gases, the chemical phenomena and concepts were modeled with a computer.

RESEARCH METHODS

The research methods of two case studies from the larger design research (Edelson, 2002) are presented in Figure 1.

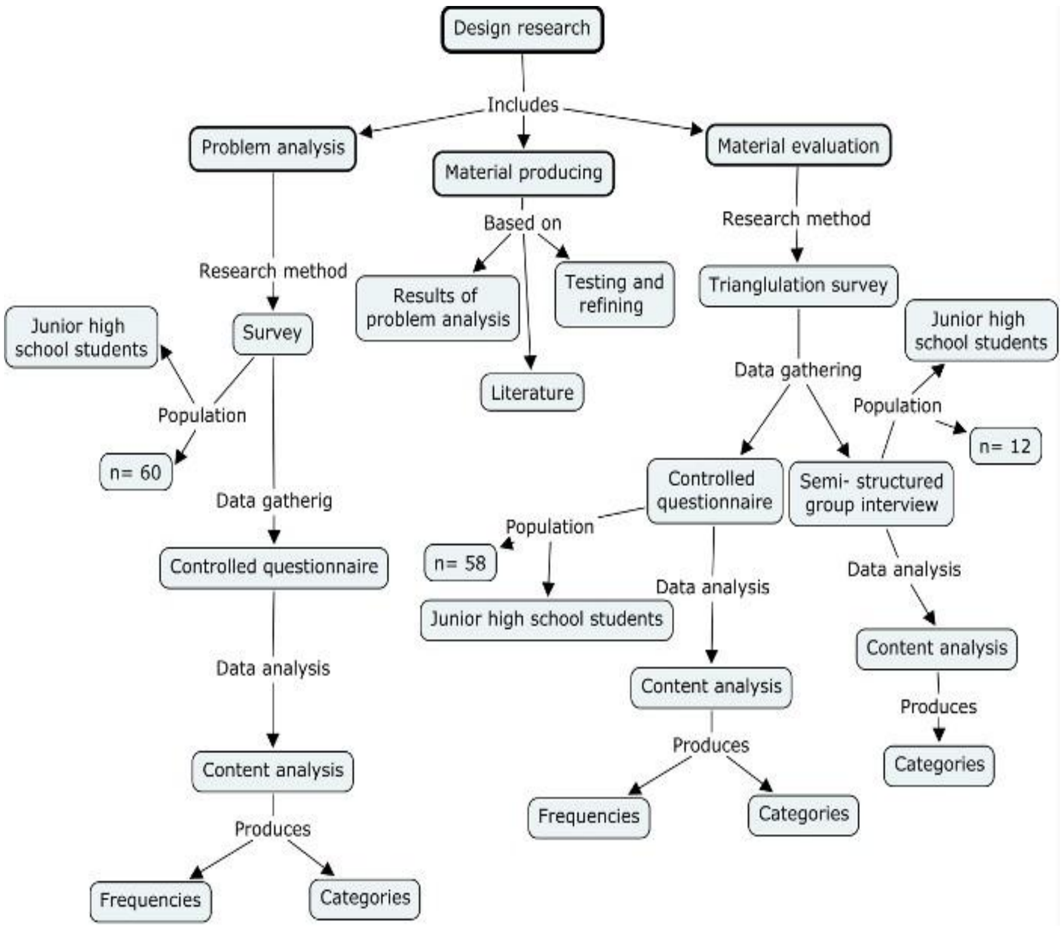

Figure 7: The research methods of this study.

A controlled questionnaire was used as a data gathering method through survey. The use of controlled questionnaire ensures a good response percent, and makes it possible to provide the respondents with instructions. The respondents can also ask for clarification if a question is not fully understood (Hirsjärvi et al., 2009). The students participated in a basic lesson about computer-based molecular modeling that is offered by the Gadolin chemistry laboratory. After the lesson, the students completed a questionnaire. The questionnaire included one closed Likert scale type of questionnaire item, and one open question. The Likert item measured the students' interest towards computer-based molecular modelling as a studying tool. The scale was from 1 to 5 (1 = strongly disagree, 2 = disagree, 3 = neither agree nor disagree, 4 = agree, and 5 = strongly agree). The respondents were asked to specify their level of agreement to the statement: "Computer- based molecular modeling was interesting." There was also the possibility to indicate that the respondent has no opinion on the matter (0 = I have no opinion). Especially, while studying children and young people, it is important not to assume that the respondent always has an opinion (Cohen & Manion, 2009). The open question was: "Do you think that using computer-based molecular modeling would make chemistry lessons more interesting? Please, give reasons." A pilot test was conducted before the actual test and the questionnaire was revised after the pilot test. The validity of categories formed was evaluated by another researcher in chemical education.

The responses to the closed question were analyzed quantitatively. The modes and frequencies were calculated. The open question was analyzed by content analysis method which is based on grounded theory (Cohen et al, 2009). The responses to the open question were encoded by using open code type grounded theory method.

In the second case study, the developed material was evaluated by the students. The used research methods were a semi-structured group-interview and a questionnaire. In a triangulation, two or more research methods are used to measure one object. With triangulation, it is possible to obtain deeper and more reliable results compared to the use of one research method (Cohen et al., 2009).

The students had an opportunity to ask questions, if something in the questionnaire was unclear to them. The questionnaire included three parts. There were eight Likert items on how interesting students' found the different actions in computer-based molecular modelling; one Likert item on students' interest towards modeling as a whole; and two open guestions. Students specified their level of agreement to the statements by five-level Likert scale (1 = strongly disagree, 2 = disagree, 3 = neither agree nor disagree, 4 = agree, and 5 = strongly agree). There was also the possibility to indicate that the respondent has no opinion on the matter (0 = "I have no opinion"). The open questions were: "What was interesting in modeling?" and "What was uninteresting in modeling?" A pilot test was conducted before the actual test, and the questionnaire was revised after the pilot test.

Randomly selected students (n = 12) participated in three semi-structured group interviews. A group interview may be a better way to canvass junior high school students' feelings and interests than a personal interview, because young people feel more encouraged to reveal their real opinions when they have the support of a group (Hirsjärvi & Hurme, 2009). The interviews were held in a quiet space with no interruptions. There were open questions about the thoughts that the modeling had invoked. The students had the opportunity to freely describe and discuss their thoughts with the group. The interviewer presented themes and encouraged the students to speak out. Also one of the Likert items from the questionnaire, the one that measured the students' interest towards the modeling as a whole was asked again. The purpose of this was to find out how similar the answers were compared to the questionnaire responses. The structure of the interview was tested and revised twice before the actual interview. The interviews were videotaped to ease the transliterating. The videotaped material was transliterated and analyzed by material-based content analysis method. The data was encoded with open-coding system. The used categories emerged from the data. The validity of categories formed was evaluated by another researcher in chemical education.

RESULTS

As a result of the first case study (a problem analysis), the students found the molecular modeling with computer interesting. The interest level was measured with a five-level Likert scale.

Students felt that using molecular modeling in schools would make studying chemistry more interesting. The mode of the answers was 4. 24 students chose the option 4 or 5. Only five of the students chose the option 1 or 2. 44 students gave reasons for their opinion. 42 of the reasons were positive and two negative. The positive reasons were divided into six categories by using content analysis. These are presented in the concept map (Figure 2). Students felt that molecular modeling was interesting because (i) it gave some variety to regular chemistry lessons, (ii) it helped to improve the understanding of chemistry, and (iii) the students themselves had an active role. Working with a computer was also highly valued.

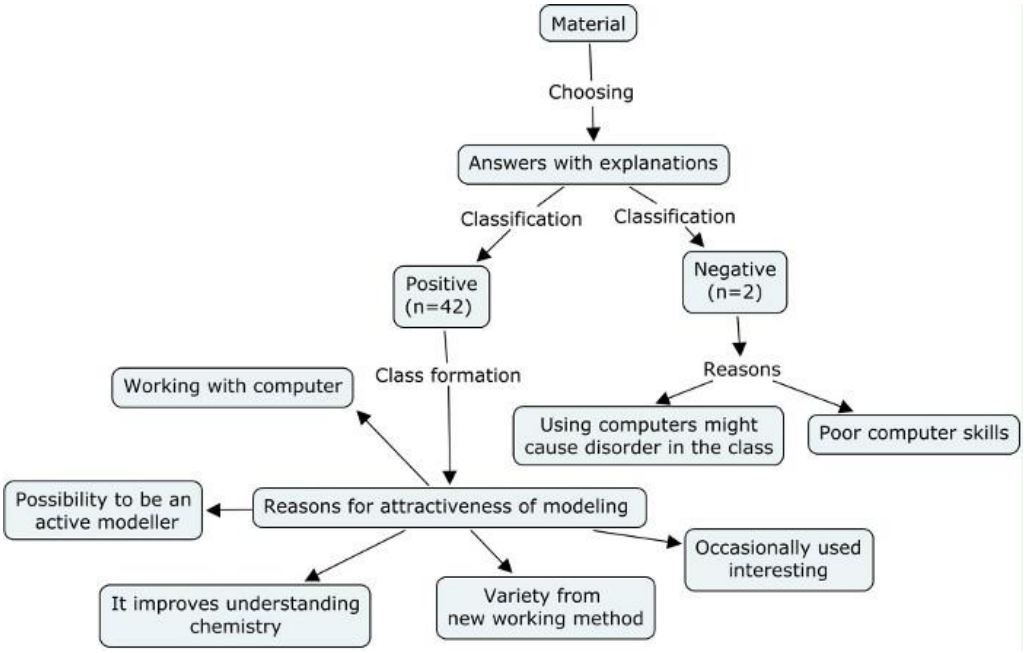

Figure 8: Concept map from the problem analysis results

The third stage of the study included two parts: an interview and a questionnaire. The responses to the questionnaire revealed that the students agreed that modeling was an interest-increasing way to study chemistry. The mode of the answers was 4. See frequencies in table 1.

The possibility to perform modeling themselves was highly valued among the students. The mode of the statement: "It was interesting to perform modeling myself" was 5, and chosen by 29 students. The students felt that the visual aids for molecular modeling increased their interest. They felt that examining molecules' three-dimensional shapes was interesting (mode 4). The students were also keen on "seeing" the molecules (mode 5), and modeling the same molecule with different models was also liked (mode 4).

The elements of molecular modeling that enable the students to examine and predict the properties of molecules were perceived to be interesting by the students. The mode of interest in explaining the molecular properties with models was 4, modeling electron densities was evaluated with mode 4, and measuring bond lengths with mode 3. Table 1 shows frequencies of answers.

Table 16: Frequencies to propositions

Proposiotion	Level of agreement 0	1	2	3	4	5	Total
It was interesting to perform modeling myself	3	2	1	5	18	29	58
It was interesting to to examine molecules' three-dimensional shapes	1	1	4	3	30	19	58
It was interesting to "see" molecules	2	3	1	13	19	20	58
It was interesting to model the same molecule with different models	1	3	3	15	24	12	58
It was interesting to explain the molecular properties with models	2	4	6	15	21	10	58
It was interesting to model electron densities	4	2	4	18	21	9	58
It was interesting to build molecules	1	2	2	9	25	19	58
It was interesting to measure bond lenghts	3	9	7	21	12	6	58

55 students answered the open question on why the molecular modeling was interesting and why it was uninteresting. The interest increasing qualities were divided into six classes. The classes are shown in table 2 with examples of the students' answers. 40 students expressed their opinion on why modeling was uninteresting, and 20 of them felt that nothing of it was uninteresting. The 20 answers were divided into five classes. Students were not keen on measuring bond properties (frequency 5), and waiting during the calculations (f. 4). Modeling was considered challenging (f. 5), and listening to the instructions was not enjoyed either (f. 3). Two students found nothing interesting at all.

Table 2: Students' opinion of the interest increasing qualities of molecular modeling

Class	F	Examples
Ability to have an active role in modeling	11	"It was fun to build molecules by myself." (Student 25) "To experience building the molecules and structures by myself" (Student 4)
Constructing molecules	14	"Most interesting was to construct molecules" (Student 21)
"Seeing" molecules	15	"To find out what a molecule looks like from different angles." (Student 29)
Explaining the properties of molecules with models	5	"To understand the relationship between molecule structure and function" (Student 53)
Enhanced understanding of chemistry	4	"Because I saw molecules and understood what was revealed in the chemistry lessons at school" (Student 45)
Wholeness	3	"Everything was interesting!" (Student 35)
Nothing	2	"Nothing was interesting" (Student 19)
n	**55**	

12 students were interviewed in three small groups. 11 students said that modeling increased their positive attitude towards chemistry. One thought that modeling was completely pointless. Students described modeling as was fun, inspiring, useful, and interesting. The feelings that the modeling invoked in the students are presented in the concept map (figure 3). 11 students were enthusiastic about the idea that modeling would be used as a tool in chemistry education. They gave reasons why modeling would bring variety to the lessons and make studying chemistry more interesting.

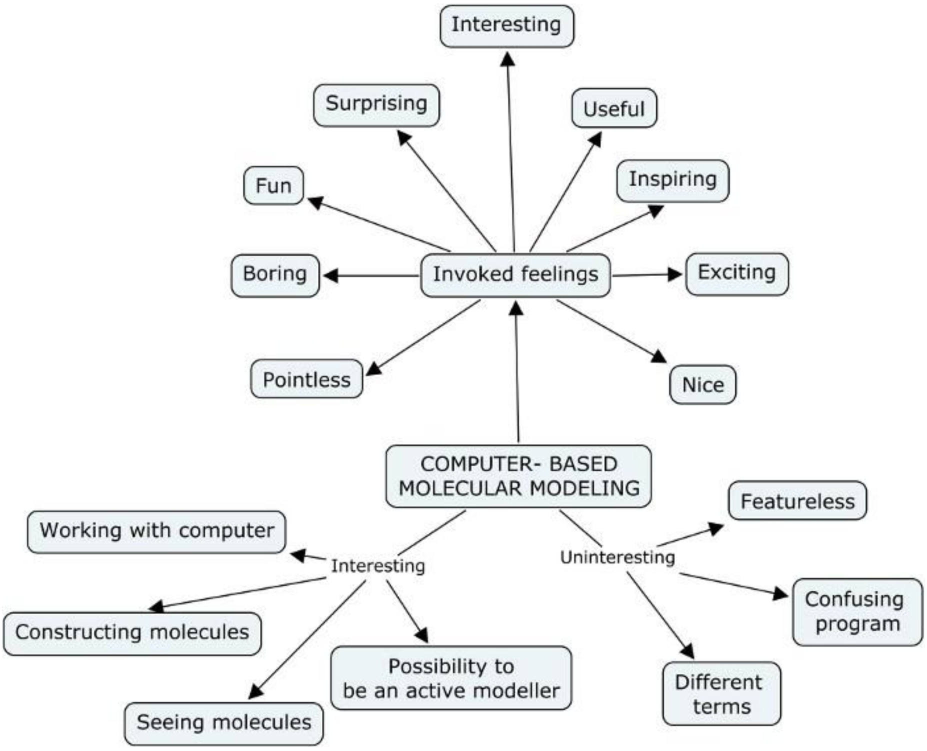

Figure 9 Students' opinions about molecular modeling

DISCUSSION

The students view computer-based molecular modeling as an inspiring way to study chemistry, and they believe that the use of molecular modeling in schools would make studying chemistry more interesting. Modeling would make lessons more versatile, and the students also felt that they would understand chemistry better if computer-based molecular modeling was used in schools. Similar results have emerged from previous researches. Jääskeläinen & Aksela (2008) found that more than half of the students found modeling with computers interesting because it brought variety to chemistry lessons. Some students felt that the interest was triggered by learning new things.

Chemistry is regarded as a difficult subject because of the invisible nature of atoms and molecules (Garnet et al., 1995). With computer-based molecular modeling, atoms and molecules can be effectively visualized to make chemical phenomena visible. As a result of this study, students found that "seeing" molecules increased their understanding of chemistry, and thus made studying chemistry more interesting.

Although the population in the problem analysis of this study was quite small (n = 60), the results strongly indicate that there is a justified need to develop computer-based molecular modeling material for chemical education in order to support interest and learning. 40 students found that molecular modeling increased their interest in chemistry. Only two students regarded modeling as uninteresting. This strong distribution is a well-justified reason to develop material that properly exploits computer-based molecular modeling in order to increase students' interest in chemistry.

As a result, material for computer-based molecular modeling was developed. Students described modeling as fun, useful, inspiring, and interesting. The possibility to perform modeling themselves was the most valued part. This result is in line with previous studies. The students become interested when they have an active role and take responsibility for their own learning (Hidi & Renninger, 2006). The visual aids were also highly appreciated. Seeing molecules was found interesting because it was a way of tangible, improved learning. In order to develop situational interest into personal interest, it is important to improve the students' knowledge, skills and self-efficacy (Hidi & Renninger, 2006; Lavonen et al., 2005). The students found that they learned chemistry better, because they were able to see molecules, and examine the molecular properties with models. Barnea & Dori (1996) studied students' attitudes towards molecular modeling, and found that students understood chemistry better via visualization. Measuring bond length was least liked, but the responses were still neutral. None of the modeling actions was found uninteresting. Many previous researches have shown that modeling is regarded as an interesting working method among students (Barnea & Dori, 1996).

The interviews supported the results from the survey analysis. The students stated that constructing molecules, and seeing them, improved learning, and invoked their interest. Triangulation as a research method improves reliability when two research methods have shown similar results to one problem.

In this study, one goal was to develop material for computer-based molecular modeling that would increase the attractiveness of chemistry. The material that was developed as a result supported students' interest in chemistry quite well. In previous research, 16% of students of the same age found modeling very interesting. The interest was measured with a five-level Likert scale (Jääskeläinen & Aksela, 2008). In this study, modeling material was developed in order to increase interest, and 38% of the students found modeling very interesting. The results are not directly comparable, but the difference indicates that the material fulfilled its goals. Most importantly, the students' interest toward chemistry increased and they gave justified reasons for it after working with computer-based molecular modeling software. They found modeling fun, but also useful for learning. When planning chemistry education, students' opinions should be heard and teachers should use working methods that students find useful and interesting. In this study, the students spontaneously emphasized that modeling improved their learning and was therefore considered interesting. As a result of this study, the development of more computer-based molecular modeling material for chemistry education is highly recommended in the future.

Needs for further studies emerged from the present study. It is necessary to study how more stable interest development could be supported with computer aided molecular modeling. It is also important to study how modeling affects the quality of learning. Students' interest and enthusiasm towards studying chemistry can be supported by including computer aided molecular modeling in chemistry education. Even though a single working method can not offer a solution to improve the attractiveness of chemistry, versatile and well-chosen working methods combined can have a tremendous influence on students' interest. Computer-based molecular modeling is one way to improve the attractiveness of chemistry among young chemistry students.

RELATIONSHIPS BETWEEN SCHOOL SCIENCE CHOICE IN SECONDARY AND ROSE ATTITUDINAL FACTORS

ma.manassero@uib.es

ABSTRACT

This paper presents an empirical analysis about the influence of affective factors on the first choice of science school subject carried out by secondary students, across sex and education type (coeducation or single-sex education). The science attitudinal factors are extracted by means of principal component factor analysis from a wide array of variables of ROSE questionnaires (image of science, preservation of the environment, attitudes toward school science, out-of-school experiences and expectations on a future job). The data analysis involves a discriminant analysis, which contrasts the predictive power of the attitudinal factors regarding the choices (election – non election of science subject) and across three groups, sex (girls and boys) and education type (girls educated in single sex school). The results prove the predictive power of the attitudinal factors on choices, identify the significant factors for the science choice in each group and describe the differences among the groups. Its implications for school science education are discussed.

Keywords: *science education, school science, subject choice, scientific vocations, gender differences, single-sex education.*

INTRODUCTION

The crisis of scientific vocations is a general concern today in many countries, as they realize it challenges seriously the future because science and technology (forward S&T) lie in the core of the economic development in knowledge societies (Zamora, 2004). The Rocard report (Rocard, Csermely, Jorde, Lenzen, Walwerg, & Hemmo, 2007) expresses this general concern at its very beginning:

> *"In recent years, many studies have highlighted an alarming decline in young people's interest for key science studies and mathematics. Despite the numerous projects and actions that are being implemented to reverse this trend, the signs of improvement are still modest. Unless more effective action is taken, Europe's longer term capacity to innovate, and the quality of its research will also decline. Furthermore, among the population in general, the acquisition of skills that are becoming essential in all walks of life, in a society increasingly dependent on the use of knowledge, is also under increasing threat."(p. 7)*

Some years ago the European Education Council (European Council, 2003) had already addressed this challenge proposing to European Union the following benchmark to 2010:

> *"To increase at least 15% the number of graduates in mathematics, sciences and technology, reducing the imbalance in the representation of men and women."*

The European Union also summoned a monographic congress under an expressive motto "Europe needs more scientists" to study this question (Gago, 2004).

Besides, the most dramatic problem that school science education addresses today is affective: boredom, indifference and difficulty that are translated into the students' abandonment of scientific careers, when the moment of choosing studies or careers arrives (Fensham, 2004; Millar and Osborne, 1998; Pérez, 2005; Rocard, et al., 2007; Williams, Stanistreet, Spall, Float & Dickson, 2003). The youths' lack of interest toward scientific and engineering careers is a well confirmed fact (Vázquez and Manassero, 2008). Furthermore, the students who choose a science career justify it because they perceive a better labour future, but their opinions on the lack of attractiveness and difficulty of science are similar to those who made the opposite choice (Lindahl, 2003).

The research on choice identifies sex as an influential factor, whose predictive power is similar to previous school marks (Croxford, 2002). Sex is so important into professional development that careers are usually classified as masculine (sciences, engineering) and feminine (care professions, education, health, etc.). The masculine mark of S&T arises from the historical prevalence of scientists men and the lower participation of women in science, although it is also rooted in other features, as the boys' highest choice for technology, physics and chemistry and girls' for biology and health (Farenga and Joyce, 2000; Manassero and Vázquez, 2003; Stark and Gray, 1999; Vázquez, 1999).

> *"When looked at [science education] from a gender perspective the problem is even worse as, in general, girls are less interested in science education than boys. As shown by the OECD Programme for International Student Assessment (PISA) study, at 15 years old, there is already a strongly gendered pattern and in most countries females are significantly less interested in mathematics than males. This pattern of gender differences continues with women choosing fewer academic studies in math, science and technology (MST). In fact, at the European level, girls account only for 31% of MST graduates (2004)." (p. 11, Rocard, et al. 2007)*

Summing up, science has a gender bias, which produces some empirically contrasted gender differences in science education: boys exhibit better school achievement and attitudes toward school S&T than girls. The gender differences in school achievement, motivation, attitudes and out-of-school experiences related to science are favourable to men, in general, and they constitute the core of the so called andocentric bias of S&T (Jones, Howe & Rua, 2000; Vázquez, 1996, 2000).

This andocentric bias of S&T is a stereotype that arises in the school context dominated by the coeducational model (girls and boys are taught together within the classrooms). The evident differences between adolescent boys and girls, affective and cognitive abilities, learning styles, etc., learning difficulties in specific subjects (maths and science for girls, language for boys) and the uneven interactions and coexistence in coeducational classrooms contribute to harm mainly women, and affect their consequent school choices (Ainley and Daly, 2002; Salomone, 2003; Smithers and Robinson, 2006; Spielhofer, Benton and Schagen, 2004; Younger and Warrington, 2005). The boy-favourable biased stereotype on gender differences in S&T is an indicator of the inability of coeducational school to meet the differential needs of boys and girls in science classrooms. Thus, some have turned to educate girls and boys separately (SSE) as an alternative educational practice to non critical coeducation (COED).

A further gender-related issue is the educational controversy between single-sex and coeducational schooling. Although coeducation has many positive aspects, the facts accounted for in the previous paragraph also provide evidence that COED has not been effective to eliminate sex discriminations against women; the critics even claim that COED could indirectly contribute to hide and to favour discrimination (Fize, 2003). The controversy is centred in determining the educational effectiveness between SSE and COED. The advocates of the single-sex education (boys and girls are taught separately), claim that both sex groups, mainly in the adolescence, sustain different learning interests, styles and paces that are not easily concealable, and whose requirements are not appropriately met by coeducation. They argue that sex separation contributes to isolate boys or girls from the learning harmful interferences that are emitted by the other sex, so that the learning is reinforced and improved for all, boys and girls (Salomone, 2003). The single-sex education seeks to improve the coexistence, by avoiding the noxious effects of those inconvenient interactions and by better addressing the specific learning difficulties (language in boys and sciences and mathematics in girls), as a mean to eliminate the sexist discriminations in education (Younger and Warrington, 2005). Some studies even suggest that the SSE could partially break the gender stereotypic choice bias in S&T, increasing the women's election of S&T (Ainley and Daly, 2002; Spielhofer et alt, 2002), although others consider that the evidences about the superiority of SSE are still ambiguous (Smithers and Robinson, 2006).

Closing the loop, the sex also influences the students' attitudes, which includes the attitudes toward the school science, the global image of S&T, the job and vocational expectations, the interests, etc. (Vázquez & Manassero, 1995, 2007a). These affective variables also influence the academic elections and, thus they could be good explanatory variables on the subject choice (Breakwell and Beardsell, 1992; Gardner, 1975; Haste, 2004). Some additional studies address the interactions between the science election and other variables: perception of S&T and school science, the scientists' image, interaction with significant adults, depression, low science self-esteem and lack of information on scientists and S&T (Cleaves, 2005).

Nevertheless, studies on the relationship between attitudes and S&T election have been relatively scarce (Gardner, 1975; Qualter, 1993). In this framework, the elections of secondary school subjects are determined by diverse school factors, such as the pleasure on subject, the school qualifications, the perception of the personnel value and competence, the professional and academic orientation information, and other out-of school variables such as informal resources (museums, clubs, etc.), friends and peers, relatives, etc. (Blenkinsop, McCrone, Wade & Morris, 2006).

This study seeks an empirically based answer to these issues, through a reanalysis of the ROSE project database (Schreiner & Sjoberg, 2004; Vázquez & Manassero, 2007b), by considering the science election as the dependent and central variable. This study aims to empirically identify the attitudinal factors related to S&T that account for the first choice of a science subject in secondary compulsory education. It also analyzes the mediation of sex (co-educated boys and girls) and the education type (coeducation or single-sex school) on the choice. The initial hypothesis expects that these groups will display different attitudinal profiles of science election.

The school choice of eligible science subjects is the first step to a potential scientific vocation and career. Thus, these factors are expected to become core hints to innovate, improve and promote better scientific literacy and scientific vocations in the school science education among the youths both, in scientific and non scientific people.

METHOD

ROSE (Relevance of Science Education) project aims to gather and analyze evidences about the perception of young pupils, who finish their compulsory secondary school about different S&T-related issues.

Sample

The participants are 15/16 year-old students belonging to 32 public and private schools in the Balearic Islands (Spain), each school contributing with just one 10-grade group class chosen at random; four groups in the sample belong to the alone girls school. The whole sample involved 860 students who responded the ROSE questionnaire (Schreiner & Sjoberg, 2004), and are divided by sex and type of education into three groups, denominated girls, boys and alone girls.

The alone girls group involves 120 girls educated in a school only for girls, although the school staff is mixed. the group of girls (409) and boys (331) are students educated in mixed schools (COED schools). The mainstream youths are 15 (59%) and 16 (29%) years old; a majority (57%) had chosen one science subject the year of questionnaire application, although the group of alone girls shows a higher proportion (85%).

Table 1. Description of the orthogonal and not correlated factors (average zero and standard deviation unit) that arise from the factor analysis on the questionnaire items (149) for the whole sample. Each factor displays its label and a brief content description, its range (maximum and minimum), reliability, item number, and the text of the item with the highest factor load.

FACTORS	Content / first item of the factor	Minimum	Maximum	Cronbach's Alpha	N of Items
BRICOLAGE	Activities with diverse tools and machines in the daily life G68. used a car jack	-2,132	3,644	0,909	23
SCHOOL	Perception of the school science f6. I like <Science at school> better than most other subjects	-3,031	2,417	0,869	15
FARM	Farm activities (care of animals,…) g9. cared for animals on a farm	-2,502	3,498	0,848	15
TICS	Use of technologies of information and communication g56. sent or received e-mail	-3,390	2,057	0,805	7
HOME_ASTRONOMY	Home activities and basic astronomy g59. baked bread, pastry or cake	-2,634	3,043	0,707	8
MEASUREMENT	Use of simple measure apparatuses g49. used a measuring ruler, tape or stick	-3,770	2,423	0,770	6
ECOLOGISM	conservationist attitudes to the nature g19. The natural world is sacred and should be left in peace	-4,340	3,347	0,439	9
PROGRESS	Image of progress of S&T h2. Thanks to science and technology, there will be greater opportunities for future generations	-5,101	3,406	0,624	8
SOCIAL	Social image of S&T h8. Science and technology are helping the poor	-3,323	3,748	0,250	7
CREATIVE JOB	Creativity and invention in a future job b10. Making, designing or inventing something	-3,274	2,950	0,734	4
POWER_FAME	Power and fame in a future job B25. Becoming 'the boss' at my job	-3,376	3,168	0,480	5
USING_APPARATUS	Operating simple scientific apparatuses g34. used a microscope	-2,516	3,837	0,496	7
LEISURE	Value the leisure time in a future job b12. Having lots of time for my friends	-3,644	4,149	0,672	4
ECOAPATHY	Apathy before the conservation of environment d14. Environmental problems should be left to the experts	-3,896	3,649	-0,196	5
SELF_ACTUALIZATION	Upgrade and development in a future job b15. Working with something I find important and meaningful	-4,111	2,897	0,327	7
ILLNESS	Experiences of health and illness g31. taken medicines to prevent or cure illness or infection	-2,763	3,611	0,603	4
INTEREST	Dynamism and illusion in a future job g20. Working at a place where something new and exciting happens frequently	-3,612	2,814	0,652	3
RISKS	Risks in the nature because of S&T d12. It is the responsibility of the rich countries to solve the environmental problems of the world	-3,450	3,092	0,252	4
TEAM_WORKING	To collaborate with people in a future job b1. Working with people instead of things	-3,036	3,631	0,544	3

Instrument
The ROSE questionnaire has hundred of items that are merged into different thematic sub-questionnaires. The instrument of this study uses 149 items of the ROSE questionnaire (Schreiner and Sjøberg, 2004; Vázquez and Manassero, 2007a), belonging to four attitudinal scales and an inventory of out-of-school experiences.

The four attitudinal scales are labelled My future job (27 items), Me and the environmental challenges (19 items), My science classes (18 items), My opinions about science and technology (16 items). The pupils express agreement or disagreement on each item, ticking one point on a four-point Likert scale, whose categories rang from 'Disagree' (1) to 'Agree' (4).

The inventory “My out-of-school experiences” lists 69 activities related to S&T, and the students are requested on each activity to score the frequency of their practice on a 4-point Likert-type scale, ranging from never (1) to often (4).

Procedures
The dependent variable is the current choice of one science school subject that year, which is a dichotomised variable that takes two values: science (one science subject was elected by pupil), and non science (any science subject was elected by pupil). Given the dichotomised nature of the dependent variable (election of science), a discriminant analysis (DA) is applied to classify cases into the groups (science, non-science) through the attitudinal factors. The DA identifies the significant attitudinal factors that better predicts the students’ choice of school science across sex and education variables.

The independent variables (predictors of pupil’s choice) are the attitudinal variables that are drawn out from the direct scores of 149 ROSE items. This large set is reduced to a cluster of 19 normalized orthogonal attitudinal factors (average, zero; standard deviation, unit) by means of an exploratory principal component factor analysis (PCA) with a Varimax rotation (table 1).

The study uses student’s sex (girls and boys) and type of education (single-sex or coeducation) as grouping variables for the three groups described in the sample: boys (co-educated boys), girls (co-educated girls) and alone girls (girls educated in single-sex).

RESULTS

Table 2 summarize the descriptive statistic of factors for the whole sample and the three groups (boys, girls and alone girls) and the probability of significance of the differences between science and non science groups. The mean factor scores show remarkable variations along factors and between the students who have chosen science and those who have not, and among sex and education sub-groups.

Boys score much higher than the two girl groups for the Bricolage activities and score much lower for Home activities. The alone girls (single-sex education) display much higher scores than the other two groups for the School factor, TICs and Illness activities, and Self-actualization job feature, and much lower scores for the preference for Environmental jobs. The specific comparison to girls shows that the alone girls display overall higher scores than girls in most of factors, which point out an alone girls’ general attitudinal profile more favourable toward S&T; furthermore, the scores are much higher than girls in the Measurement activities, Image of Progress of S&T, and the Eco-apathy attitude. Girls display higher scores that the other two groups in the Perception of the S&T Risks.

In regard of the differences between science choosers and rejecters, for the total sample, science group has higher scores than non science counterpart in almost all factors; the only exception are Leisure and Risks factors. However, the differences are only statistically significant (p <.01) and favourable to science choosers group in four factors: attitudes toward the School science, TICs and Illness activities, and S&T Progress; nevertheless, none of that differences are relevant (effect size higher than 0.30).

Table 2. Descriptive statistics of the attitudinal factors obtained from the exploratory principal component factor analysis for the total sample and the groups defined for this study: girls (COED), boys (COED) and alone girls (girls in single-sex education).

Within the girls group (COED), science girls show higher scores than non science girls along all the factors, except Risks. However, the differences between science and non science girls are only significant (p <.01) and favourable to science girls for the S&T Social Impact factor, although the difference between groups is not relevant.

Within the boys group (COED), the score averages for science and non science groups are relatively homogeneous (very close to each other) and near to the null value for almost all the factors, except in the case of the Bricolage (very high) and Home (very low) activity factors. Science boys display higher scores than non science boys in most of the factors, but the differences are statistically significant (p <.01) just for TICs activities.

The factor average profile of the alone girl group differs noticeably from the profiles of the other two sub-groups (boys and girls). On the one hand, alone girls mostly show higher and more positive factor score averages than the other groups. On the other hand, science alone girls do not show a higher score profile than non science alone girls, rather the non science alone girls score higher than science alone girls in some factors. Yet, the differences between science and non science alone girls are only significant (p <.01) and relevant for two factors (Farm and Illness activities); non science alone girls show much higher score for Farm, while science alone girls score higher in Illness.

TEAM_WORKING	-0,11	1,047	-0,118	1,057	0,9481	0,284	0,887	0,181	0,939	0,6508

The DA for the whole sample (table 3) produces six significant predictors [chi2 (6, N = 860) = 57.88, p <.0000; canonical correlation = .2558] whose predictive power is featured by the standardized coefficients values. The six significant predictors of the science election are: TICs, Illness experiences, the attitudes toward School Science, S&T image of Progress and two factors of a future job (Self-actualization and Interest).

In the group of girls, the DA produces two significant predictors [chi2 (2, N = 409) = 13.71, p = .0010; canonical correlation = .1822]. The two significant predictors (Farm activities and S&T Image of Progress) have very big positive standardized coefficients.

For boys, the DA produces two significant predictors [chi2 (2, N = 331) = 12.14, p = .0023; canonical correlation = .1906], namely TICs activities and Interest in the future job, which also display very big positive standardized coefficients.

In the alone girls group, the AD produces reversed centroids (the negative centroid for science girls) and two significant predictors [chi2 (2, N = 120) = 11.69, p = .0029; canonical correlation = .3083], namely Farm and Illness activities, which display very big standardized coefficients. The former is positive (in this case, the higher the experience in farming activities, the higher the likelihood of non choosing science), and the latter is negative (the higher the illness experience, the lower the likelihood of choosing science).

All in all, the empirical analysis on elections produces a reduced list of seven different significant factors about the decision of choosing (or not) science in secondary education. None of the seven factors is universal for all the subgroups, although some factors, as TICs, Illness, Progress and Interest repeat twice, for the total sample and at least for one of the subgroups. Farm predictor repeats for girls and alone girls, but paradoxically doing opposite roles in each group: for girls it is a positive indicator of science choice, while for alone girls indicates the opposite trend. This feature could be a cue that sound differences in science among coeducation and the girls-only education might exist.

Table 3. Significant factors and their standardized coefficients of the discriminant function obtained from the discriminant analysis for the total sample and the groups: girls (COED), boys (COED) and girls alone (girls in single-sex education).

TOTAL SAMPLE		GIRLS		BOYS		ALONE GIRLS	
Significant Factors	Coef.	Significant Factors	Coef.	Significant Factors	Coef.	Significant Factors	Coef.
SCHOOL	0,4065	FARM	0,6602	TICS	0,8456	FARM	0,6711
TICS	0,5397	PROGRESS	0,7552	INTEREST	0,5834	ILLNESS	-0,6493
PROGRESS	0,3862						
SELF_ACTUALIZATION	0,3210						
ILLNESS	0,5082						
INTEREST	0,2987						

The alone girls group achieves an outstanding landmark: it reaches a rate of correct classification of elections through DA almost total (96%) in the subgroup that chooses sciences, which is much bigger than any other rate.

DISCUSSION

This study displays through the DA the different role of the significant discriminant factors, which suggests a reflection about the differential relevance of the several attitudinal variables and their original ROSE scales from which they are drawn. In particular, the scale on the environmental future is the only one that does not produce any significant factor for the classification in none of the groups; this result is contrary to some PISA attitudinal findings, which could deserve further scrutiny. On the other hand, the inventory of out-of-school experiences (Illness, Farm and TICs), the future job features (Interest and Self-actualization) and the scale of attitudes toward School science and image of science provide the majority of the significant empirical factors.

Globally, the analyses carried out for each of the subgroups taken into account for this study (boys, girls and alone girls) show completely different discriminant predictor profiles. The comparison between girls and alone girls groups fuels the controversy between coeducation and differentiated education (single-sex), as the evidence presented here confirms different disjoint profiles for every group; at least, this break suggests that both types of education produce differential effects for science choice. Although the decision about the effectiveness of each kind of education requires deeper research, these results suggest that single-sex education (SSE) exhibits a somewhat better effectiveness inducing girls toward science, as the rate of alone girls who choose sciences is higher than co-educated girls (COED), and the same is true for the process of discriminant prediction of choice.

The implications of these findings launch a basic and evident message for science education, already underlined by others (e.g. Rocard et al., 2007): the education of key attitudinal factors must be given some priority in science teaching, according to the innovation of science education for improving learning of science and science choice. As Rocard et al. (2007) suggested:

"Recommendation 3. Specific attention should be given to raising the participation of girls in key school science subject, and to increasing their self-confidence in science." (p. 22)

ROSE (The Relevance Of Science Education) is an international project with about 40 participating countries. ROSE is organized by Svein Sjoberg and Camilla Schreiner at the University of Oslo and is supported by the Research Council of Norway. Reports and details are available at http://www.ils.uio.no/forskning/rose/

ABSTRACT

Ethical aspects are an important part of science education research. This aspect is especially important because humans are the subjects of research in the field of education. Ethical aspects of the science education research are also closely connected with the type oh research approach that the researcher choose for answering the research question(s). In the field of the humanities and social sciences, two paradigms of scientific research were developed in the past. Regarding their attributes, they are called quantitative and qualitative. Each approach has special characteristics that researcher have to follow. Ethical dilemmas that the researcher has to face are hidden in each step of the research procedure. In this paper basic ethical guidelines in conducting science education research will be presented.

Keywords: *science education research, qualitative and quantitative approaches, ethics in research.*

INTRODUCTION

Ethical aspects of research should be an important part of every researcher's work. These aspects are also important for science education researchers especially because humans are the subjects of research in the field of education. Protecting human participants in the science education research is probably the most important ethical aspect of researchers' activity, but also other ethical viewpoints regarding research procedures should not be neglected. Ethical aspects of the science education research are also closely connected with the type of research approach that the researcher chooses for answering the research question(s). In the field of the science education research (as well as in the humanities and social science), two paradigms of scientific research were developed in the past. Reflecting their attributes, they are referred to as quantitative and qualitative, respectively. In this paper, the expression "paradigm" is used in the sense of Kuhn's contemporary definition of a scientific paradigm. According to Kuhn, paradigms are "the series of reciprocally connected assumptions about social phenomena, providing the philosophical and notional frame for studying them" (Kuhn 1974, p. 39). Therefore, a paradigm is the sum of values, convictions and assumptions that, with regard to a particular scientific discipline, indicate which values, beliefs, convictions, assumptions, laws, etc., are shared by the adherents of a certain scientific paradigm, and according to which the adherents form their tradition of scientific research.

In this paper the main characteristics of qualitative and quantitative research will be analyzed and basic ethical guidelines in conducting science education research will be presented. The role of science education researcher will be explained in the framework of assuring premise for ethical quantitative and qualitative research in all phases of research process, from research planning, during conducting research, to writing research report and presenting the results and conclusions to the public.

RESEARCH APPROACHES IN EDUCATION

Quantitative research, with its empirical analytical methodology and unidirectional or linear research process, models research according to approaches following by natural sciences. The basis of quantitative research is the belief that there is a reality led by stable natural laws, independent of people and waiting to be discovered. Its objective is to reach reliable, exact, precise, measurable, verifiable, and objective observations, which in social or educational sciences would have the same value as findings in natural sciences. In quantitative research, the research problem is handled part by part. Quantitative researchers in science education approach different aspects of the phenomenon (e.g. science teaching and learning) and deal with individual variables (e.g. students' science test achievements, motivation level, mental abilities...), but on a larger number of units, most frequently on a representative sample of a population (e.g. students, teachers...), since our tendency is to generalise the established results. The use of the standardised research instruments, use of statistical methods, forming hypotheses and their reliable verification are some of the major methodological principles of the empirical-analytical methodology.

The qualitative research regarding its ontological, epistemological and methodological aspect is not a consistent phenomenon; namely, it combines different kinds of research, e.g. a case study, life history, action research and others. Bogdan and Biklen (2003) use the term »qualitative research« as the superordinate concept, joining different research approaches with certain common characteristics as well. With the expression "qualitative research" we denote that kind of research where the basic empirical material, collected in the research process, consists of verbal descriptions or narratives. Further, the collected material is worked on and analysed in words without numerical operations (Mesec, 1998). According to Creswell (1998), qualitative research is a research process designed on a clear methodological tradition of research, where researchers build a complex, holistic framework so that they analyse narratives and observations, conducting the research work in the habitat. The researcher is directly included in the environment where the data collection take place, which helps him/her to observe the object(s) of the research. In this context, the researcher should be aware of the fact that with his/her participation and the researched situation itself they influence on the phenomena that it is researched. Further, to qualitative research we also attach attributes such as phenomenological approach, the use of hermeneutical procedures of explanation, an orientation towards the process and the dynamic.

The aim of qualitative study in science education research is to gather data in the form of rich content–based descriptions of people, events, and situations by using different, especially non–structural, techniques, to discover the stakeholders' views, and to analyze the gathered data verbally, and finally to interpret the findings in a form of a concept or grounded theory which is contextually dependent. Qualitative empirical research is oriented towards examining individual cases (idiographic approach). The study is mostly conducted as a study of one case only or a smaller number of cases, therefore the techniques of data collection are adjusted to a small scale analysis, enabling the researcher to get to know the social environment. The qualitative research is carried out in line with the principles of the interpretative paradigm, i.e. the focus is on examining the subjective experiences of an individual and on recognizing the importance which the individual attaches to specific events, whereby not even the subjective views of the researcher of the studied situation are neglected. The aim is integrated and detailed cognition of phenomena, preferably in natural and concrete circumstances, for the researcher is interested in the context of the pursued activities. As part of the environment, the researcher is not only able to understand what the person is conveying in a form of a rational message and standardized speech, but also the indirect implications of this speech with a specific syntax, contextual lapses, hidden meanings and speech breaks are perceived. Wishes, expectations, interests, needs and personal opinions of the people included into the research should help the researcher to better comprehend the examined phenomena.

At data collection one is not limited to one source or one technique only. Apart from the data acquired by interviews and observation, usually also different documentary sources are used, such as personal documents (a birth certificate, an employment record, a passport, letters, photos…), different records produced in the process of data collecting, transcriptions of tape recordings, video material, etc. It is important emphasize that only the triangulation – the pluralism – of data collection techniques and their mutual combination can provide for linking the findings of individual phenomena or aspects into a meaningful integrity. Triangulation is a strategy enabling researchers to understand the observational object significantly better and in a more comprehensive manner. Multiple triangulation, assuming the combination of multiple triangulation forms, i.e. the triangulation of investigators, theories, data sources, methods and/or disciplines, provides for the exhaustive data interpretation (Denzin & Lincoln 2000; Wolcott, 1994).

At analyzing the gathered qualitative data statistical procedures are also not used, but predominantly the qualitative analysis, the essence of which is searching for codes in the analyzed materials (Bryman, 2004). The main part of the qualitative analysis of the material is formed by the coding process namely, i.e. interpreting the analyzed text and attributing the meaning (e.g., the meaning of key words, notions, codes) to its individual parts (Bryman, 2004; Charmaz 2006). Qualitative analysis of the material starts with defining the coding units, followed by the appropriate phenomena records according to our judgment and analyzing the characteristics of these phenomena, and ends with the development of the grounded theory (Glaser & Strauss, 1967). The grounded theory is read out as a narrative about the phenomenon, which was the subject of the study. It is characteristic for the theory to be constructed from the collected data and to develop in the course of the entire research process. The grounded theory is contextually bound, i.e. it is not a general theory (the findings cannot be generalized without additional definitions), but the theory of a narrower scope, valid only in certain environments and certain conditions.

It needs to be stressed that the role of the researcher and the person studied differ in the qualitative and quantitative paradigms. The quantitative paradigm typically defines the role of a person studied as mainly limited to data acquisition and the introduction of those changes established by other researchers into practice. In order to ensure the highest level of objectivity (as well as validity and reliability), a demand for separating the research object from the research subject is employed in quantitative research. This puts the researcher in charge of the research process, whereas the person studied primarily represents the source of information. It is typical for the qualitative paradigm that the researcher and those under research formulate the studied situation together.

Any research involving humans or nonhumans immediately introduces questions of ethics. Consideration of ethical issues is integral to the qualitative and quantitative research process. Researchers have two basic categories of ethical responsibility (Gravetter & Forzano, 2009): (1) responsibility to the individuals, who participate in their research studies (protecting human subjects in the process of research so that no harm is made); and (2) responsibility to the discipline (e.g. natural sciences, humanities, social sciences, educational sciences – science education) to be accurate and honest in the selecting the sample and method to answer to the research question(s) and in the reporting of research results.

ETHICS IN SCIENCE EDUCATION RESEARCH

Ethics is a branch of moral philosophy dealing with the criteria by which behavior should be judged as morally good or bad, and the standards by which behavior ought to be regulated. Code of ethics for research is issued as guidance for the proper moral conduct of researchers (Gomm, 2009). Ethics can be conceived to consist of several areas (Kitchener, 2000; Kitchener & Kitchener, 2009). (1) Descriptive ethics studies how people actually behave and what ethical values they actually hold. This area belongs to empirical science. (2) Normative ethics is concerned with the questions: How should an individual behave; what properties are valuable or good? (3) Meta-ethics asks questions about the meaning of ethical words, the logic of justifying moral decisions, the reality of moral properties, and so forth. (4) Finally, applied ethics uses principles and insights from normative ethics to resolve specific moral issues in concrete and particular settings. Science research ethics is thus an example of applied ethics.

Ethical point of view is an important component of everyday live, and we should also be aware of its importance in designing and conducting science education research. Ethics should be considered not only in the research design but also in the relation to the research participants and researchers. When the researcher is directly involved in the research procedure, especially in the qualitative research design, the relationship between the researchers and participants in the research, could be very demanding for both parts (Cencič, 2002).

HISTORICAL HIGHLIGHTS OF ETHICAL ISSUES

Until the end of World War II, researchers established their own ethical standards and safeguards for human participants in their research. It was assumed that researchers, bounded by their own moral compasses, would protect their participants from harm. The major impetus for a shift from individualized ethics to more formalized ethical guidelines was the uncovering of the brutal experiments performed on prisoners in Nazi concentration camps. A variety of sadistic ˝medical experiments˝ were conducted on unwilling participants. When these atrocities came to light, some of those responsible were tried for their crimes at Nuremberg in 1947. Out of these trials came the Nuremberg Code, a set of 10 guidelines for the ethical treatment of human participants in research (Gravetter & Forzano, 2009). The Nuremberg Code laid the groundwork for the ethical standards that are in place today. A similar set of ethical guidelines was published in 1978 when the National Commission published The Belmont Report: Ethical Principles and Guideline for the Protection of Human Subjects of Research. The Belmont Report Commission considered three principles derived from ethical considerations that should frame researchers´ efforts (Gravetter & Forzano, 2009): (1) beneficence, or the maximization of ˝good outcomes for science, humanity and the individual research participants˝ while risk to human subjects, harm, or outright wrong were to be minimized; (2) respect, by which they meant treating human participants with respect, dignity, courtesy, and agency; and (3) justice, or ˝ensuring ... those who bear the risk (as research participants) are (those) who benefit from it,˝ as well as ensuring that the procedures are ˝reasonable, nonexploitative, and carefully considered˝ as well as ˝fairly administered˝. Furthermore, the Belmont Commission spelled out six norms of scientific research (Lincoln, 2009) that should act as guidelines for the conduct of research, including: (1) the use of a valid research design, as free of flaws as possible to make it; (2) a researcher competent to conduct the research; (3) the identification of the consequences of the research, principally for research participants; (4) the appropriate use of sample selection; (5) the assurance of voluntary informed consent, and (6) information to research participants as to whether harm will be compensated.

In general, ethical issues have arisen around four major frameworks (Lincoln, 2009): (1) the ethical treatment of those with whom, on whom, and for whom (on whose behalf) we conduct research; (2) ethical considerations of the contexts in which research is conducted; (3) ethical considerations for a globalized ethnographic practice; and (4) ethical considerations surrounding data and the preparation of reports, especially in the question of for whom reports are created.

Ethical decision making is intimately intertwined with all phases of the research process. Beginning with the identification of a research topic, continuing with the choice of methods for studying that topic, and proceeding through each and every aspect of data collection, analysis, presentation, and reanalysis, decisions made feed back into theory development and influence subsequent rounds of research problem identification. Each stage of the research process shares some common ethical issues while, at the same time, each study, qualitative or quantitative, basic or applied is unique.

ETHICAL ISSUES AND HUMAN PARTICIPANTS IN SCIENCE EDUCATION RESEARCH

As we work with individual participants, we need to respect them individually, such as by not stereotyping them, using their language and names, and following guidelines such as those found in the Publication Manual of the American Psychological Association (APA, 2001) for nondiscriminatory language. The researcher has no right to harm the participants or subjects, physically, emotionally, or psychologically. On the contrary, the researcher has a responsibility to ensure the safety and the dignity of the participants.

Four protections need to be provided when conducting research with human participants (Lincoln, 2009): (1) participants should be fully informed regarding the nature of the research and the potential consequences of participating, known as informed consent, including the right to withdraw from the study at any time prior to publication; (2) deception, when it occurs as a part of the research design, must be accompanied by a full debriefing at the end of the study, to include all participants who have been duped or otherwise deceived; (3) participants must be guaranteed that they will not be identified by name or otherwise, referred to as anonymity or confidentiality; and (4) personal records will not be opened without the express consent of research participants, frequently referred to rights to privacy.

The general concept of informed consent is that human participants should be given complete information about the research and their roles in it before agreeing to participate. They should understand the information and then voluntarily decide whether or not to participate. But simply telling participants about the research does not necessarily mean they are informed, especially in situations where the participants may not be competent enough to understand. This problem occurs routinely with special populations such as young children, and developmentally disabled people. In these situations, it is customary to provide information to the participants as well as to a parent or guardian who also must approve of the participation.

Often, it is impossible to provide participants with complete information about a research prior to their participation. For example, if participants know the true purpose of a research study, they may modify their natural behaviors. To avoid this problem, researchers sometimes will not tell participants the true purpose of the study. One technique is to use passive deception, or omission, and simply withhold information about the study. Another possibility is to use active deception, or commission, and deliberately present false or misleading information (Gravetter & Forzano, 2009). In these situations, a researcher has a special responsibility to safeguard the participants and he must debrief the participants by providing a complete explanation as soon as possible after participation in completed.

In most quantitative research reports, the results are presented as average values that have been collapsed across a large group of individual participants, and there is no mention of any individual participants, code numbers, or code names. In qualitative research it is very often the case that researchers want to hide the identity of their research participants by using pseudonyms to mask particular biographical features or other obvious identifiers. While in principle this can work, there are frequently occasions where the ways that people speak, the topics that they discuss, the sorts of stories that they tell – all of these things can make the participants identifiable by other people (particularly in small samples or in tightly-knit communities). Further, it can be difficult for researchers to know which features of the data would be recognizable by others. It may be that one of the anecdotes told in an interview is widely associated with a given person (who has told it on other occasions to other people) and by using and citing it as data, the researcher inadvertently reveals the identity of the person who provided it (for more information see Gibson & Brown, 2009). In short, it is easy to promise anonymity, but in practice it can be much harder to safeguard.

The protection of data is a key issue in research. The nature of research work, and the fact, working in more than one place, and often requires researchers to share their data (in part or in the whole) with other people (e.g. by presenting at conferences, discussing with colleagues or supervisors, or working in research teams), all mean that the location of data can be hard to specify and contain. Researchers can discuss confidential information only for appropriate scientific or professional purposes, and only with persons clearly concerned with such matters; they may disclose confidential information with the appropriate consent of the individual or another legally authorized person on behalf of the participant, unless prohibited by law. Very careful thought needs to be given to how data is stored and distributed, and the mechanisms that are used to contain it within the bounds of the researcher´s control. It is also very important to think about what happens to data after a project has finished. A common approach is to assume that the best policy is to simply destroy data once the research is complete. But it is not always obvious that the destruction of data is necessarily the best option. A researcher may have an interest in preserving data so that they can show how they reached their conclusions, or in order to revisit their analysis later in order to clarify or develop it. Even research participants may have an interest in having access to such analysis so that they can trace their presence within an analysis.

CONCLUSION

In making decisions about the science education research process, it is, as for all research involving human subjects, vital to consider the ethical dimensions of the approach to be taken and the specific ethical issues that might be raised in working through a project. The general issues that need to be thought are: informed consent, confidentiality, avoiding harm, integrity and professionalism. In research, ethical issues must be considered at each step in the research process. Ethical principles dictate: (1) what measurement techniques may be used for certain individuals and certain behaviors, (2) how researchers select individuals to participate in studies, (3) which research approach may be used with certain population, (4) how studies may be carried out with individuals, (5) how data are analyzed, and (6) how results are reported.

Although the final responsibility for the protection of human participants rests with the researcher, most human-participants research must be reviewed and approved by a group of individuals not directly affiliated with the specific research study. Each institution or agency is required to establish a committee called an Institutional Review Board, which is composed of both scientists and nonscientists, and examines all proposed research involving human participants with respect to some basic criteria (e.g. minimization of risk to participants, informed consent, documentation of informed consent, data monitoring, privacy and confidentiality ...). The Institutional Review Board can require a research proposal to be modified to meet its criteria before the research is approved.

Various professional bodies provide ethical guidelines for researchers to follow in the design and conduct of their research. ˝Ethical guidelines comprise statements of intent and appropriate practice that can be used to help researchers to work through the ethical dimensions of their research˝ (Gibson & Brown, 2009, p. 60). Awareness of and affiliation to such guidelines has become standard practice. Such guidelines have the general aim of protecting the research participants and other interested parties to the research, including the researcher, as well as helping to maintain professional research standards, promote public confidence in research, and minimize legal risk.

ABSTRACT

One goal of science education is to endorse scientific literacy for all people with a complete understanding of the nature of science and technology, and their interdependence with the society. This study explores the Turkish preserves primary school teachers' (n=52) and preserves early childhood teachers' views (n = 56) on STS issues. Data were collected through an adopted 26-items "Views on Science–Technology–Society" instrument. The analysis revealed that preserves teachers often confuse the definition of technology with science and they have varied views about the influences of society on science. According to most of the participants, the reason of doing scientific research in their country is, for example, to be independent from other countries and to get financial profit. In addition, preserves science teachers claimed that technological developments can be controlled by citizens. The results indicated that high percentage of participants from two groups was aware of tentative nature of science.

Keywords: Science–Technology–Society*, Preserves Teachers, Teacher Education*

INTRODUCTION

Science helps address issues that are of concern to the general population. Because of this reason, it is important to the public. Scientific principles have been and continue to be applied to address issues, concerns, and problems that people face in the day-to-day aspects of living. Scientific research has value and importance to person to the extent that it helps address problems of a practical nature. How science is taught and learned can determine its significance to the majority of students, not only to those planning careers in scientific fields.

According to American Association for the Advancement of Science (2001), one goal of science education is to endorse scientific literacy for all people with a complete understanding of the nature of science and technology, and their interdependence with the society. The aims of science education have been changed from pointing out cognition to ways of acquiring knowledge (Mansour, 2009). Some research indicate that college students have many misconceptions about the real world and they seem to keep these views even after completing and succeeding in advance courses dealing with scientific concepts and theories. To internalize interpretations of the real world, they need to have real experiences (Yager, 1996).

National Science Teachers Association (NSTA, 1990) views STS as the teaching and learning of science in the context of human experience. STS can be described as a student-centered teaching approach which has characteristics needed to reform effort that concerns goals, curriculum, instruction, and assessment. Science Technology Society (STS) program is to provide a real-world connection for the student between the classroom and society. The process should give the student practice in recognizing potential problems, gathering data about the problem, considering alternative solutions, and considering the consequences based on a particular decisions (Yager,1990).

It has been argued that to empower the students as citizens, there is a need to emphasize STS (Kolstoe, 2001). The National Science Teachers Association described STS as the central goal for science education in 1980s:

> The goal of science education during the 1980s is to develop scientifically literate individuals who understand how science, technology, and society influence one another and who are able to use their knowledge in their everyday decision-making. The scientifically literate person has a substantial knowledge base of facts, concepts, conceptual networks, and process skills which enable the individual to learn logically. This individual both appreciates the value of science and technology in society and understands their limitations. (as cited in Yager, 1996, p.4)

How science is taught and learned can determine the ways of people thought about the relationship among science, technology, and society.

This study had multiple purposes. First aim was illuminating and comparing preserves teachers' views, who enrolled different programs, on the STS issues in Turkey. Another purpose was to document the preserves teachers' views on the STS issues before and after taking a science education course. Although these preserves teachers will teach science to children, they were not from science education programs.

METHODOLOGY

Participants

For this study, we collected data from 108 preserves teachers. All of them volunteered to participate in the study. Fifty-two enrolled in science teaching course at Primary School Teacher Education Program and fifty-six enrolled in science education course at Early Childhood Teacher Education Program. The purpose of the courses provided for preserves teachers in this study was to provide meaningful and practical learning experiences that prepare students to create effective science learning environments for elementary school students or children in early childhood period . The course created an environment where the preserves teachers were active participants in both discussions and hands-on science activities rather than passive receivers of information.

Instrument

The Views of Science-Technology-Society (VOSTS) instrument was composed of 114 multiple-choice items that addressed a broad range of STS topics (Aikenhead, Ryan and Fleming, 1989). In this study, 26 "Views on Science-Technology- Society items" selected and translated into Turkish by Kahyaoğlu (2004) were used. Test reliability was calculated using the split half technique by correlating the odd-numbered item results with even-numbered item results. The test reliability coefficient was found to be 0.71 (Kahyaoglu, 2004). The instrument includes seven subscales. These subscales and the item numbers belonging to each scale were: (a) science and technology (three items), (b) influence of society on science/technology (four items), (c) influence of science/technology on society (five items), (d) characteristics of scientists (two items), (e) social construction of scientific knowledge (four items), (f) social construction of technology (two items), and (g) nature of scientific knowledge (six items).

One example item from VOSTS is given as follows:

10111. Defining science is difficult because science is complex and does many things. But mainly science is:
Your position, basically:
A. a study of fields such as biology, chemistry and physics.
B. a body of knowledge, such as principles, laws and theories, which explain the world around us (matter, energy and life).
C. exploring the unknown and discovering new things about our world and universe and how they work.
D. carrying out experiments to solve problems of interest about the world around us.
E. inventing or designing things (for example, artificial hearts, computer, space vehicles).
F. finding and using knowledge to make this world a better place to live in (for example, curing diseases, solving pollution and improving agriculture).
G. an organization of people (called scientists) who have ideas and techniques for discovering new knowledge.
H. No one can define science (Aikenhead et al., 1989)

Data Collection and Analysis

The adapted VOSTS questionnaire was administered to the participants as pre- and post-test in Spring 2009. The data were analyzed the frequency distribution for each item to characterize the trends in participants' perceptions of the science, technology, and society issues.

RESULTS

Results are organized under the titles of subscales. Due to the limitation of space, selected results are discussed in detail.

*Science and Technology.*The adopted VOSTS survey included three items for the science and technology subscale. The results of Science and Technology' subscales were given in Table 1.

The first item of this scale refers to the science definition. The data stated that there is no consensus on the definition of science among preserves primary school teachers (PPST) and preserves early childhood teachers (PECT). While 27% of preserves primary school teachers (PPST) define science as a body of knowledge on pre-teset, 37% of them define science as a body of knowledge on post test. On the other hand, the highest portion of preserves early childhood teachers (PECT) (pretest: 45%, posttest: 46%) define science as improving the world.

The second item of this scale is about preserves teachers' definition of technology. On pretest, 29% of PPST thought technology as the application of science. After post test, this value increased to 35%. In contrast, 29% PECT thought technology as new process, instruments, tools, machinery etc. or practical devices.

The third item assessed participants' views on issues concerning the interdependence of science and technology. On pre and post test, the highest percentage of PPST (64%) and PECT (88%) thought science and technology closely related because scientific research leads to practical applications in technology, and technological developments increase the ability to do scientific research.

Table 1: Summary of the Results of Science and Technology Subscale

		Preserves Primary School Teachers		Preserves Early Childhood Teachers	
		Pre-test	Post-test	Pre-test	Post-test
Science and Technology	1.Defining science	C %35 B %27 F %19	B %37 C %25 F %25	F %45 C %34 B %14	F %46 C %34 B %11
	2.Defining technology	C %35 B %29 G %17	B %35 G %25 C %21	B %27 G %25 C %23	C %29 B %27 G %23
	3.Interdependence of science and technology	B %79 A %12 C %6	B %64 A %27 C %6	B %84 A %13	B %88 A %9

*Influence of Society on Science and Technology. T*his subscale was composed of four items. The highest portion of PPST (42%) and PECT (52%) reported that there is need for their country to finance science in order to make their world a better place to live in, on pre and post test (Table 2).

The analysis of second item revealed that the highest portion of PPST (33%) and PECT (32%) thought the ethical and religious views are effective on how and what scientists think. They believe that scientists unconsciously choose research topics that support their cultural views.

An interesting finding emerged from the item six. On post test, while 33% of PPST claimed that the more students learn about science and technology; the more the informed the future public will be, the high proportion (48%) of PECT reported the public will better understand the views of experts and will provide the needed support for science and technology on pre and post test.

Another important result of this subscale that 33% of PPST claimed that the encouragement and opportunity to become a scientist is given by schools, family, and community on pretest. This portion decreased to 17% on post test. Even though the highest portion of PECT thought same way with PPST on pre and post test (pretest: 41%, posttest: 32%), it is possible to see decreasing on post test.

Table 2: Summary of the Results of Influence of Society on Science and Technology Subscale

		Preserves Primary School Teachers		Preserves Early Childhood Teachers	
		Pre-test	Post-test	Pre-test	Post-test
Influence of society on science/ technology	4. Government	D %40 A %33 C %15	D %42 A %29 C %15	D %43 A %27 C %21	D %52 C %27 A %16
	5. Ethics	B %23 G %19 F %17	B %33 F %31 E %12	B %27 D %18 G %18	B %32 E %21 F,G%14
	6. Education institutions	D %37 C %25 A %21	C %33 A %27 B %19	D %45 C %39 A %11	D %48 C %29 B %89
	7. Public influence on scientists	E %33 B %31 D %19	D %27 B %25 E %17	E %41 D %21 F %20	E %32 D %29 B %21

Influence of Science/Technology on Society. This subscale composed of five items. According to results on pre and post test of first item for this subscale, the highest percentage of PPST (pretest: 54%, post test: 67%) and PECT (pretest: 63%, post test: 59%) believed that scientist are concerned with all the effects of their experiments because the goal of science is to make our world a better place to live in (Table 3).

Another result of this subscale is that the highest portion of PPST (pretest: 33%, post test: 29%) and PECT (pretest: 39%, post test: 45%) believed that scientist and engineers should decide because they have the trainings and facts but the public should be involved-either informed or consulted. Almost half of the PPST (pretest: 46%, posttest: 48%) claimed that scientists are better at solving any practical problem.

According to them, their logical problem solving minds or specialized knowledge gives them an advantage. However, the big proportion of PECT (pretest: 61%, posttest: 54%) suggested that scientists are no better than the others, because in everyday life scientists are like everyone else and experience and common sense will solve everyday practical problems.

According to results of fourth item for this subscale, the highest percentage of PPST (pretest: 42%, post test: 58%) and PECT (pretest: 57%, post test: 55%) believed that scientific and technological developments make Turkey less dependent to other countries.

In the last item of this subscale, 31% of PPST on pretest claimed that the more advanced the country's science and technology, the richer that country will be. This portion decreased to 19% on post test. On the post test, 48% of PPST responded as science and technology develop in a country, more modern, accurate, and destructive weapons are built. Even though the highest portion of PECT thought same way with PPST on pre and post test (pretest: 41%, posttest: 30%), it is possible to see decreasing on post test.

Table 3: Summary of the Results of Influence of Science/Technology on Society Subscale

		Preserves Primary School Teachers		Preserves Early Childhood Teachers	
		Pre-test	Post-test	Pre-test	Post-test
Influence of science/ technology on society	8. Social responsibility of scientists/ technologists	C %54 E %15 D %12	C %67 E %8 D %6	C %63 D %13 E %13	C %59 B %13 D %13
	9. Contribution to social decisions	D %35 C %33 B %12	C %29 D %29 B %19	C %39 D %36 A,B %7	C %45 D %45 A %5
	10. Resolution of social and practical problems	A %46 D %31 E %14	A %48 D %25 B,E %10	D %61 A %29 E %5	D %54 A %34 C,G %4
	11. Contribution to economic well-being	B %42 A %35 D %10	B %58 A %25 D %12	B %57 A %30 D %5	B %55 A %25 D %11
	12. Contribution to military power	C %31 A %29 B %15	A %48 C %19 B %17	A %41 D %23 C %13	A %30 D 18 B 14

Characteristics of Scientists. There were two items under the characteristics of scientists subscale.

According to results on pretest and post test of first item for this subscale, the highest portion of PPST (pretest: 44%, posttest: 42%) and 39% of PECT on post test believed that the best scientists display some characteristics such as very open-minded logical, unbiased, and objective in their work since they improve the ability of science (See Table 4).

Another result of this subscale is that the highest percentage of PPST (pretest: 46%, post test: 42%) and PECT (pretest: 59%, post test: 50%) believed that there are no difference depending on the sex with respect to the process and product of science and they thought the source of the differences in the discoveries as the differences between individuals.

Table 4: Summary of the Results of Characteristics of Scientists Subscale

		Preserves Primary School Teachers		Preserves Early Childhood Teachers	
		Pre-test	Post-test	Pre-test	Post-test
Characteristics of scientists	13. Standards/ values that guides scientists at work and home	B %44 C %19 D %14	B %42 C %35 A %12	C %45 B %25 E %16	B %39 C %38 E %13
	14. Gender effect on the process and product of science	G %46 H %17 B %8	G %42 H %15 D %12	G %59 B %11 H %9	G %50 H %23 E %11

Social Construction of Scientific Knowledge. There were four items in this subscale.
According to results on pre and post test of first item for this subscale, the highest percentage of PPST (pretest: 50%, post test: 42%) and PECT (pretest: 38%, post test: 45%) believed that scientist publish their discoveries because this publication as both to benefit personally from any credit, fame or fortune that a discovery may bring; and to advance science and technology by sharing ideas publicly, and thus building upon each other's work (See Table 5).

Another result about second item for this subscale, the highest portion of PPST (pretest: 25%, posttest: 37%) and 34% of PECT on post test thought that science is no different from other professions in terms of the rule breaking.

The other result stated that on pretest 37% and on posttest 42% of the PPST believed that scientist can be helped by the ideas, experiences, or enthusiasm of people with whom they socialize. On the other hand, while 39% of PECT believed same thing with PPST, this portion decreased to 29% on post test.

According to results on pre and post test of fourth item for this subscale, the highest percentage of PPST (pretest: 31%, post test: 31%) and PECT (pretest: 29%, post test: 30%) believed that country makes a difference in the scientific research because of the reason as the education and the culture.

Table 5: Summary of the Results of Social Construction of Scientific Knowledge Subscale

Social Construction of Technology. There were two different items in this subscale. Table six shows the results of Social Construction of Technology subscale.

More than half of the PPST (pretest: 62%, posttest: 79%) and more than half (pretest: 84, posttest: 88%) of the PECT related the decision to use a new technology with several things such as its cost, efficiency, usefulness to society, and effect on employment.

According to results on post test of second item for this subscale, the highest percentage of PPST (post test: 29%) and PECT (pretest: 36%, post test: 30%) gave the reason as the needs of consumer. It is the results of the relation between demands and profits.

Table 6: Summary of the Results of Social Construction of Technology Subscale

		Preserves Primary School Teachers		Preserves Early Childhood Teachers	
		Pre-test	Post-test	Pre-test	Post-test
Social construction of technology	19. Technological decisions	B %62 E %14 A %12	B %79 A %8 D %6	B %84 D %7	B %88 D,G,H %4
	20. Autonomous technology	F %27 C %23 D %23	C %29 A %23 D %19	C %36 D %34 A 11	C %30 D %29 A,F%16

Nature of Scientific Knowledge. There were six items on Nature of Scientific Knowledge subscale.

According to first item results of this subscale, while 37% of the PPST on pretest said that scientists will experiment in different ways and will notice different things, the highest portion of PECT (41%) claimed same thing on post-test. On the other hand, while the highest portion of the PPST (31%) on post test claimed that scientists' thinking way affects their observation, the highest portion of PECT (39%) claimed the same thing on pretest (See Table 7).

Most of the participants stated that scientific knowledge may change in the future when the investigations are done correctly. More than half of the PPST (pretest: 58%, posttest: 58%) and more than half (pretest: 57%, posttest: 70%) of the PECT claimed that by using new techniques or improved instruments, new scientists disprove the old theories or discoveries.

According to results of third item of this subscale, more than half of the PPST (pretest: 67%, posttest: 58%) and more than half (pretest: 82%, posttest: 71%) of the PECT thought hypothesis tested by experiments, if it proves correct, it becomes a theory and after a theory has been proven true many times by different people and has been around for a long time, it becomes a law.

Another result stated that the highest portion of PPST (pretest: 21%, post test: 25%) and PECT (pretest: 32%, post test: 38%) defined the scientific method as questioning, hypothesizing, collecting data and concluding. The other result of this subscale is that most of the participants said that the facts do not necessarily mean that asbestos causes cancer. The highest portion of PPST (pretest: 33%, post test: 31%) thought more research is needed to find out whether it is asbestos or some other substances that causes the lung cancer.

On the other hand, the highest portion of PECT (pretest: 48%, post test: 70%) thought asbestos might work in combination with other things, or may work indirectly. The results of sixth item for this subscale stated that the highest portion of PPST (pretest: 50%, post test: 56%) and PECT (pretest: 46%, post test: 55%) believed that one scientific idea can be interpreted differently, because they thought that the interpretation depends on the individual scientist's point of view or on what the scientist already know.

CONCLUSION

This study gives insight about the views of preserves primary school and preserves early childhood teachers on STS.According to the results of this study pre-service teachers did not acquire a uniform view of science. Although many of the preserves primary school teachers defined science as content or process, preserves early childhood teachers thought it as something to make world a better place to live in. According to this study, most of the preserves teachers agreed on the effects of social contacts on the discoveries but only fifteen percent of the participants rejected the effects of social contacts which is similar to the traditional belief of objectivity of science. Participants mostly indicated the effects of different countries to the ways of looking at a scientific problem. One of the most important results of the present study is that high percentage of participants from two groups was aware of tentative nature of science.

The main purpose of science teaching course is to train scientifically literate person for a developing society. One of the important dimensions of scientific literacy is Science-Technology-Society (STS). For this reason, not just only science teachers but also all teachers must posses contemporary views about STS.

We argue that teacher training programs should be revised to improve preserves teachers' understanding of science-technology-society issues and the way that how this knowledge can be introduced to the students from any levels of education. These programs must give place to courses on philosophy and history of science.

ABSTRACT

It has been pointed out that the use of simulation poses a problem relating to the sense of reality. However, few studies have focused on curriculum design. The present research proposed “component mapping of simulation and practical work,” a new framework of curriculum design. The research featured a experiment in which elementary school students learned vegetation succession, a large temporal scale and complex system in nature, through simulation and outdoor observation. Through analyzing results of examinations and questionnaires, it was cleared the students were able not only to understand vegetation succession mechanisms but also to feel a sense of reality by linking simulation use to practical work based on curriculum design framework.

Keywords: *Simulation use, Sense of reality, Curriculum design, Vegetation succession*

BACKGROUD

Technologies play an important role in the teaching and learning of science at school. One such technology is simulation, which supports the active learning, not the passive learning, of complex systems in nature that are difficult to deal with in the school laboratory. For example, simulation shows students phenomena and processes of the microscopic motions of atoms and molecules, as well as macroscopic movements of heavenly bodies, large temporal-scale vegetation succession etc. By operating simulation parameters and by observing the results, students can acquire knowledge regarding complex systems (Wellington, 2004).

It has been pointed out, however, that the use of simulation poses a problem relating to the sense of reality (Rosenbaum et al., 2007). The problem is that students experience a virtual world, presented by simulation, as a world quite different from the actual world. For example, although the use of 3D and other technologies gives greater depth and reality to the world presented by simulation, that world is still "heavily" virtual. As a result, while students are interested in simulation, they do not find the reality of the actual world in the simulation.

However, it is possible to resolve the problem regarding the sense of reality. Attempts have been made to resolve the problem by developing simulation using new technologies. One example is "Participatory Simulation" (Colella, 2000), in which learners act as agents and focus on experiencing the simulation using mobile computers. By helping learners physically experience a virtual world, this simulation helps them link the virtual world and the real world. "Environmental Detectives" (Squire & Klopfer, 2007) and "Outbreak@The Institute" (Rosenbaum et al., 2007) are simulations integrating mobile computers and GPS. These simulations offer a good combination of virtual world and real world. Traveling in the real world, learners can experience simulation presented during their travels.

While many earlier studies toward resolving the sense-of-reality problem in simulation have focused on the use of new technology, few studies have focused on curriculum design. Studies that focus on curriculum design include those on how to integrate instruction and learning activities using simulation with practical work, such as field activities, as well as on how to design such activities.

The importance of such studies lies in acquiring views leading to effective use of existing excellent simulations. It has been said that, in science curriculums, it is not the isolated use of technologies, but the integrated use of technologies and practical work that is effective in teaching and learning (Osborne & Hennessy, 2003). If the sense-of-reality problem in simulation is resolved by improving curriculum design, it may be possible to eliminate the shortcomings of existing excellent simulations and continue using them. However, few studies have been made that propose such views for curriculum design.

With this background, the present research proposed "component mapping of simulation and practical work," a new framework of curriculum design. The research featured a experiment in which elementary school students learned vegetation succession, a large temporal scale and complex system in nature, through simulation and outdoor observation. Through the experiment, it was examined whether the elementary school students who learned the curriculum based on the framework were able not only to understand vegetation succession mechanisms, but also to feel a sense of reality.

A CURRICULUM DESIGN FRAMEWORK FOR LINKING SIMULATION USE TO PRACTICAL WORK

The framework proposed in the present research was below (**Figure 1**):

(a) Identifying components that can be experienced directly in practical work from simulation components.

(b) Designing practical work to ensure that learners link simulation and practical work through the direct experience mentioned in (a).

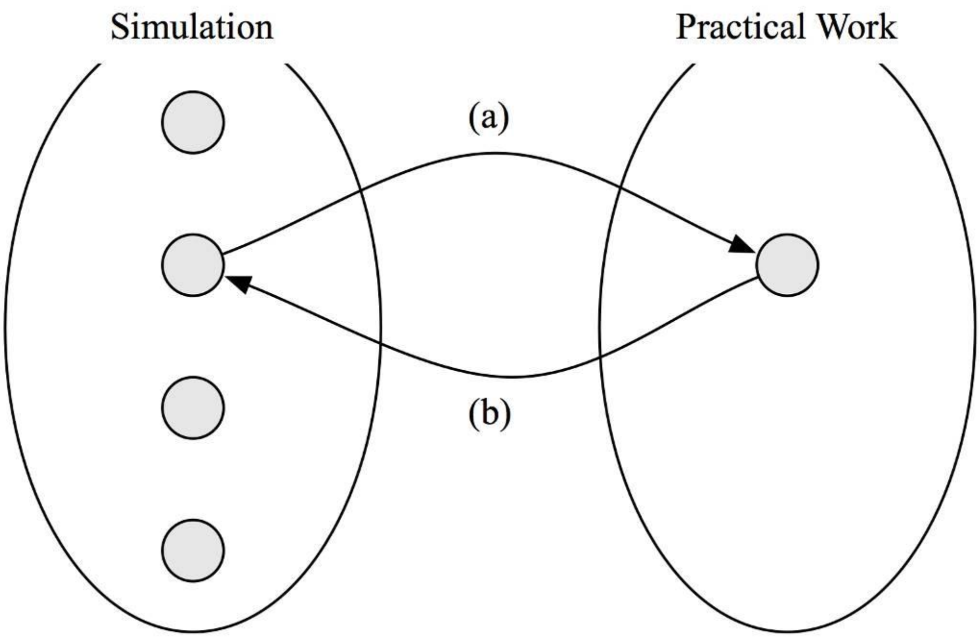

Figure 1. A curriculum design framework

On the basis of this framework, what type of curriculum can be designed? This is explained with the example of vegetation succession, which was dealt with in the experiment of present research. The vegetation succession simulation has components, such as vegetation, time, succession, disturbance (landslide and tree-cutting) and interactions. Of these components, vegetation and disturbance are actually observed outdoors. While vegetation is almost always observed easily, disturbance, which occurs infrequently, is relatively rarely seen. In this regard, according to element (a), vegetation was identified as the component. Also, according to element (b), practical work was designed in which students experienced virtual vegetation succession through use of simulation, then observed some sites with different vegetation in outdoor activities and learned the disturbance and vegetation of these sites through use of simulation results.

EXPERIMENT IN WHICH ELEMENTARY SCHOOL STUDENTS LEARNED VEGETATION SUCCESSION

PARTICIPANTS

The experiment was implemented in a sixth-grade class (36 students aged 11 to 12 years) in a elementary school in Japan, where one of the authors worked.

SIMULATION

The simulation developed by Deguchi et al.(2009) was used in the experiment (**Figure 2**). This simulation, which enables the user to experience vegetation succession, was developed with reference to "The Floristic Relay Game" (Ortiz-Barne et al., 2005). The simulation is designed for learning relationships between vegetation succession and its factors, such as disturbance and interactions. The simulation features the following six types of plants: Japanese Mallotus (*Mallotus japonicus* (Thunb. ex Murray) Mueller-Arg.), Red small berry (*Rubus microphyllus* L. fil.), Quercus serrata (*Quercus serrata* Thunb. ex. Muuray), Red Pine (*Pinus densiflora* Sieb. et Zucc.), Longstalk holly (*Ilex pedunculosa* Miq.) and Castanopsis (*Castanopsis sieboldii* (Makino) Hatusima ex Yamazaki et Masiba). Earlier studies have shown that learners who used the simulation were able to understand basic vegetation succession mechanisms (relationships between disturbance and vegetation succession, as well as relationships between interactions and vegetation succession) (Deguchi et al., 2009).

CURRICULUM

The curriculum comprised two activities: the use of simulation and outdoor observation. In the former activity, student groups, each consisting of six persons, used the simulation, then discussed relationships between disturbance and vegetation succession, as well as between interactions and vegetation succession, while referring to the simulation results (**Figure 3**). In the latter activity, after the simulation, the students went to a neighboring mountain, observed vegetation of the six types of plants featured in the simulation at three sites with early, middle and late succession stages and considered the disturbance and interactions at the sites while referring to the simulation results (**Figure 4**). The former and latter activities both took two hours, for a total of four hours.

Figure 2. The simulation designed for learning relationships between vegetation succession and its factors

EVALUATION

This experiment was evaluated in terms of the following two points: (1) Did the elementary school students who participated in the experiment understand basic vegetation succession mechanisms? and (2) Did the students feel that the vegetation succession experienced in the simulation was an event that actually occurred in the real world of nature?

Figure 3. Curriculum activity: use of simulation

For point (1), free-writing style examinations were carried out before and after the learning of the curriculum, regarding the relationships between disturbance and vegetation succession, as well as between interactions and vegetation succession. These examinations took approximately 10 minutes. In analyzing the each examination, a four-point scale was used to assess the answer students gave to the examination. A maximum score meant that the student explained vegetation succession mechanisms with technical terms students learned through the curriculum, such as dominant plant species of early stages, middle stages and late stages. Two points was assigned if the student explained vegetation succession mechanisms, but did not use technical terms. To merit a score of one the student mentioned regularity of vegetation succession, but did not explained its mechanisms. Two graders scored students' answer independently. The rates of agreement were more than 90%. About the mismatched point, it was settled by the discussion of two graders.

Figure 4. Curriculum activity: outdoor observation

For point (2), after use of the simulation and after outdoor observation, questionnaires were distributed regarding the sense of reality of vegetation succession experienced in the simulation. Questionnaires contains 13 items. These items ask students if they think the increase and decrease of number of plants, and the disturbance will really happen. These items were answered using a five-stage Likert scale: "Think so," "Somewhat think so," "No opinion," "Don’t quite think so," and "Don’t think so." The questionnaire was administered simultaneously to all students. These questionnaire took approximately five minutes. In analyzing students' answer, "Think so" is scored five points, "Somewhat think so" is scored four, "No opinion" is scored three, "Don’t quite think so" is scored two, and "Don’t think so" is scored one.

RESULTS

DID THE ELEMENTARY SCHOOL STUDENTS WHO PARTICIPATED IN THE EXPERIMENT UNDERSTAND BASIC VEGETATION SUCCESSION MECHANISMS?

Figure 5 & 6 shows the result regarding the understanding of basic vegetation succession mechanisms. Wilcoxon signed-ranks test were conducted for each scores. It was found that, regarding both relationships between disturbance and vegetation succession and between interactions and vegetation succession, the scores of the examination conducted after learning the curriculum were significantly higher than those of the examination carried out before learning (Z=-4.38, p< 0.01; Z=-5.47, p< 0.01). From these results, it can be said that students who participated in the experiment understand basic vegetation succession mechanisms.

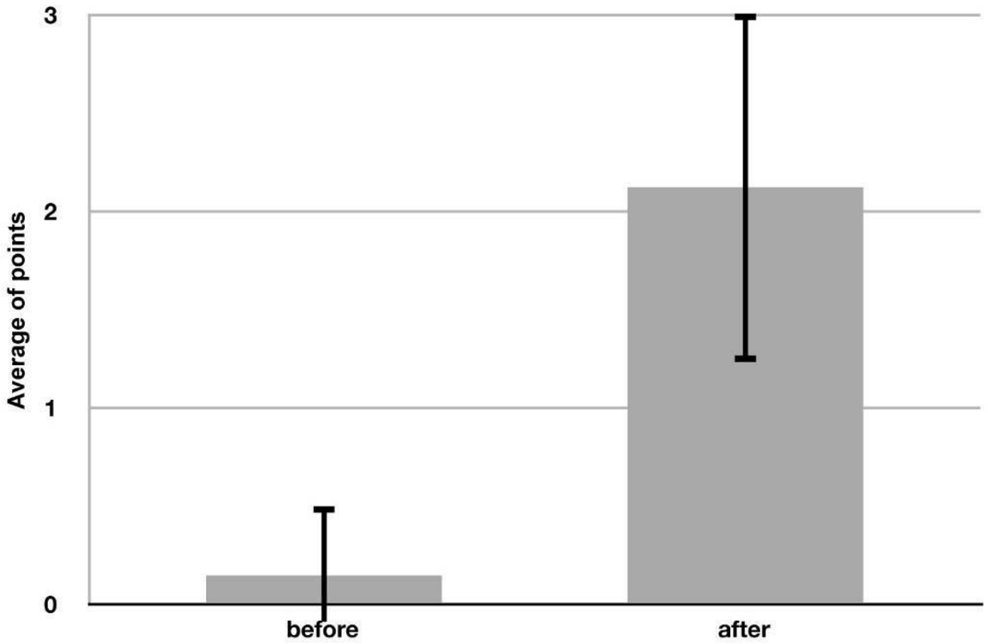

Figure 6. Average and standard deviation of the free-writing style examination regarding the relationships between interactions and vegetation succession

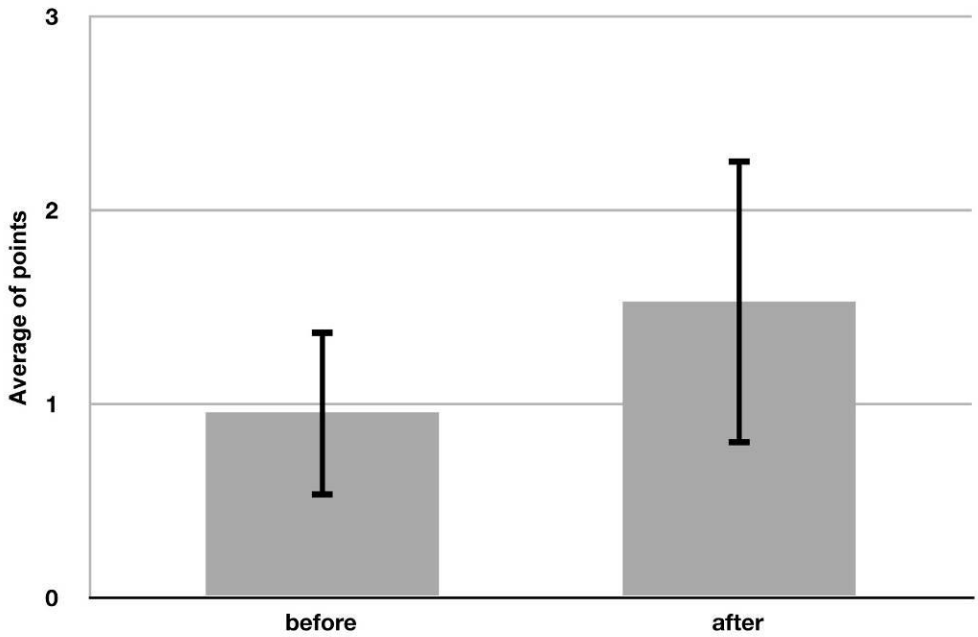

Figure 5. Average and standard deviation of the free-writing style examination regarding the relationships between disturbance and vegetation succession

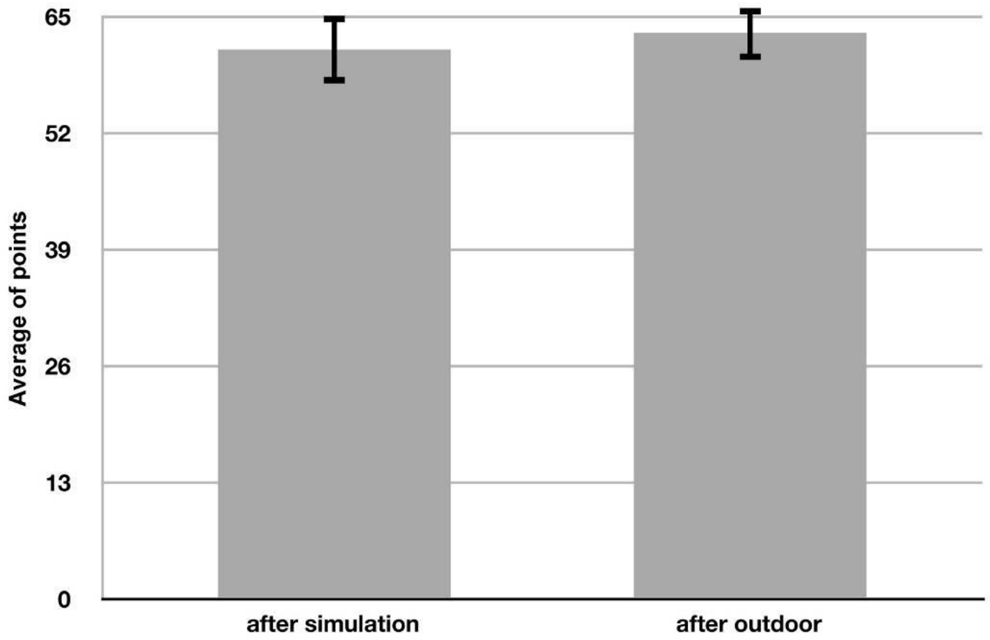

Figure 7. Average and standard deviation of questionnaires regarding the sense of reality of vegetation succession experienced in the simulation

DID THE STUDENTS FEEL THAT THE VEGETATION SUCCESSION EXPERIENCED IN THE SIMULATION WAS AN EVENT THAT ACTUALLY OCCURRED IN THE REAL WORLD OF NATURE?

Figure 7 shows the result regarding the sense of reality of vegetation succession experienced in the simulation. Wilcoxon signed-ranks test were conducted for total scores. The total scores of after the outdoor observation was significantly higher than that after the simulation (Z=-3.07, p< 0.01). From these results, it can be said that students feel that the vegetation succession experienced in the simulation was an event that actually occurred in the real world of nature.

CONCLUSIONS AND FUTURE WORK

The results of this present research revealed that the elementary school students who learned the curriculum were able to understand basic vegetation succession mechanisms. The results also showed that, although the elementary school students did not feel so much of a sense of reality after use of the simulation, they felt it after the outdoor observation. Under normal conditions, simulation and practical work support students' learning individually. On the one hand, simulation support students understand mechanisms of complex systems, and on the other hand, practical work support that student feel a sense of reality. In the present research, by intergration simulation and practical work in an effective manner, both support understanding and feeling were achieved coincidentally. In this sense, results of present research suggests that "component mapping of simulation and practical work," the curriculum design framework proposed in this present research, is effective.

The future challenges are the following two points: to ensure the generality of the present research results by carrying out experiments involving many more learners, and to create a more detailed framework and clarify its applicable scope by considering whether the framework is applicable not only to vegetation succession, but also to other areas or topics.

ABSTRACT

International scientific collaboration is necessary for survival in a knowledge-based and increasingly globalized world. This paper evaluates the practices of the Japan Society for the Promotion of Science (JSPS) Summer Program, which invites pre- and postdoctoral researchers from North America and Europe to study in Japan. The questionnaires and comments from the final report distributed to the participants revealed that, in spite of the program's short length, the participants believed that the program succeeded in the areas of professional development, international collaboration, and scientific contribution. These findings indicate that the program achieved its goal of helping excellent young researchers initiate scientific relationships that will better enable future collaborations involving Japanese universities and research institutions. Similar international programs for scientists could apply and benefit from the overall experiences of the program.

Keywords: *International Collaboration, Career Development, JSPS Summer Program, Fellowships*

1. INTRODUCTION

1.1. Mobility of Human Resources and International Collaboration

Mobility of human resources in science and technology has become a central aspect of globalisation (OECD, 2008). The Japanese government has been driving an aggressive agenda to promote science and technology, which support domestic economic growth in the long term. Today, the government strongly advocates inviting the most talented and qualified individuals to study in Japan, as evidenced by measures such as the 300,000 International Students Plan and the Project for Establishing Core Universities for Internationalization, which were enacted in 2008. Thus, the expansion of exchanges among universities and the acceptance of international students has been a key governmental policy.

Moreover, international cooperation is a proven mechanism for promoting excellence in scientific research (UNESCO, 1999). Scientists collaborate across borders for a variety of reasons: to bring together the most talented and qualified individuals; to pool intellectual, technological, and financial resources; and to effectively address scientific questions (UNESCO, 1999). While we still need to address the problem of college-educated students having difficulty finding scientific careers (e.g., NAS et al., 1996; Ogawa, 2004), for young scholars, postdoctoral fellowships can serve as a launching pad to an academic career that is almost as important as the Ph.D. programs in which they initially trained (Ronald, 2009).

1.2. The Role of Scientific Academies

JSPS has played a pivotal role in the administration of a wide spectrum of domestic and international scientific programs since its establishment in 1932. The society implements a variety of researcher-invitation programs for various career stages and serves to support researcher exchange (MEXT, 2008). The JSPS Summer Program is tailored to researchers at the start of their careers.

This research looks at whether the program is a legitimate strategy for attracting individuals to the profession and for nurturing the next generation of scientists. Although some earlier works looked at fellowship programs from various perspectives, few research studies have evaluated the achievements of fellowships in Japan. Moreover, in the last 20 years, limited analysis has been conducted on the data compiled about young scientists by the organizations involved; this is attributable to the fact that their international activities do not focus on education first. Of course, many factors influence such achievements, and it is difficult to untangle them, but there are enough existing data and information to identify some of the links between mobility and broader science and innovation outcomes (OECD, 2008).

2. OBJECTIVES AND METHOD

This paper evaluates the 2008 JSPS Summer Program primarily by deciphering participants' comments in questionnaires and a final report. The author's ongoing observation of the program provided additional support for the evaluations in this research. We conclude the paper with a discussion of future implications.

One way to view the problem is from the perspective of higher education, considering it "is required to be characterized by its international dimension: exchange of knowledge, interactive networking, mobility of teachers and students, and international projects" (UNESCO, 1998). We initially laid aside "mobility of teachers and students" and focused on the following dimensions, paraphrased in our words:

- Exchange of Knowledge → Professional Development
- Interactive Networking → International Collaboration
- International Projects → Scientific Contribution

3. PROGRAM OVERVIEW

This section focuses on the general aspects of the program. The program began in 1990 under the auspices of the Ministry of Education, Culture, Sports, Science and Technology (MEXT) and in collaboration with the National Science Foundation (NSF) as a program in which scholars were invited to Japan. Since its transfer to JSPS in 2003, other countries have participated in the program, which encourages excellent young researchers to initiate scientific relationships that will better enable future collaborations involving Japanese universities and research institutions. Owing to its successful history and vast accumulation of practical knowledge, the program should be used as an example when JSPS or other organizations institute similar invitation programs.

As Figure 1 shows, the program is implemented under the joint auspices of JSPS and the Graduate University for Advanced Studies (Sokendai). Sokendai arranges a one-week orientation and final meeting at the end of August. JSPS's overseas offices support recruitment and hold pre-departure meetings in cooperation with the headquarters of the partner academies in each country.

Each year, JSPS receives applications through the following overseas academies: NSF, British Council, Centre National de la Recherche Scientifique (CNRS), Deutscher Akademischer Austauschdienst (DAAD), and Canadian Embassy. Each nominating authority selects its awardees, or Fellows. Table 1 lists the 2008 Fellows.

The program lasts for two months each summer, as shown in Table 2. The Fellows first take part in an orientation to the Japanese language, cultural experience (comprising a home stay and other components such as folding papers and tea ceremonies), and a public poster session. Next, participants have an opportunity to participate in cooperative research at a Japanese university or research institute. At the end of August, the participants get back together to present reports on their summer experiences. In terms of financing, Fellows receive round-trip airfare, maintenance allowances, a domestic research-trip allowance, overseas travel insurance, and allowance for research-related expenses.

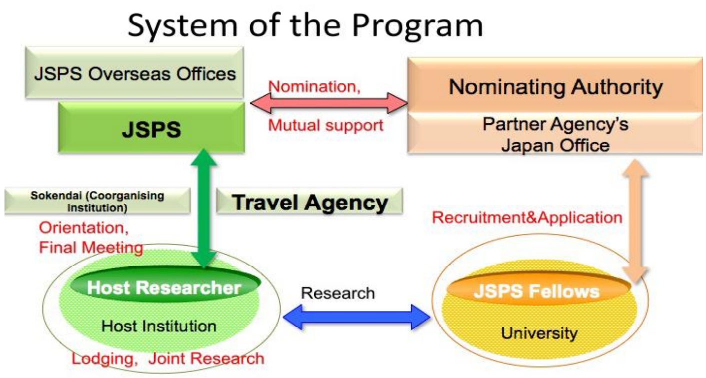

Figure 1. System and organizers

Table 1. Quota for each country in 2008

Country (Nominating Authority)	U.S. (NSF)	U.K. (British Council)	France (CNRS)	Germany (DAAD)	Canada (Canadian Embassy)	Total
Quota	63	11	8	14	18	114

Table 2. Activities in 2008

Week(s)	Activities
1	Arrival and Registration
1	Move to Camping Place, Opening Ceremony
1–2	Orientation (Language Classes, Cultural Experience, Poster Presentation, Home Stay, and Special Lectures)
2	Move to Host Institutions
2–8	Cooperative Research, Report Submission, Informal Interview
8	Move to Tokyo, Final Meeting (Representatives' Oral Presentation, Farewell)
8	Departure

4. RESULTS

We asked for feedback from the participants (i.e., Fellows and their host researchers) in the form of questionnaires and comments, if any, in their final reports.

4.1. Questionnaires

As shown in Tables 3 and 4, to identify participants' impressions of the program and their research experiences, we focused on survey data extracted from a questionnaire originally conducted in 2008 at the conclusion of the program. Targeting 114 Fellows and 114 host researchers who were involved in the program, the questionnaire asked about the participants' reasons for participating, their assessment of the program, and Fellows' achievements, including whether they thought there was any possibility of future collaboration. Among those asked to participate, 109 Fellows (96%) and 45 host researchers (39%) responded to the questionnaires. Fellows were from a range of academic levels: 16 were working on their master's degree, 90 were in a doctoral program, and 3 were postdoctoral researchers. We derived our major research findings from questions F7, F8, F10, F12, H4, H5, H6, and H9.

We first looked at professional development. Figure 2 shows the participants' evaluations of whether the initial research objectives were achieved. On the Fellows' questionnaire (question F8: To what degree did you achieve your research objective?), half of the people considered their achievements to be "satisfactory," while the host researchers mostly responded "beyond expectations" and "fully accomplished" in response to question H6 (To what degree did the Fellow achieve his/her research objective?). Most participants thought the research objectives were at least satisfactory. The next part will discuss the fact that most host researchers evaluated the Fellows' achievements higher than the Fellows did.

Table 3. Questionnaire Given to Fellows.

	Fellows' Questionnaire
F1	How did you learn about the program?
F2	What is your primary motive for participating in the program?
F3	Were the pre-departure communications useful to you in preparing to participate in the program?
F4	Was the information provided in the orientation sufficient?
F5	Were the Japanese language classes appropriate and effective?
F6	Were you satisfied with the introductory program to Japanese culture?
F7	How often did you exchange research opinions or ideas with Japanese colleagues?
F8	To what degree did you achieve your research objective?
F9	What aspects of the program were the most interesting or valuable to you?
F10	Was this research experience in Japan useful in your professional development?
F11	What is your evaluation of the overall program?
F12	What do you think is the possibility of conducting your future research in Japan?

Table 4. Questionnaire Given to Host Researchers

	Hosts' Questionnaire
H1	How did you become acquainted with the Fellow?
H2	What is your primary motive for participating in the program?
H3	Was JSPS's preliminary information useful to you after the fellowship was awarded?
H4	What do you think of setting the fellowship tenure at two months?
H5	How often did you exchange research opinions or ideas with the Fellow?
H6	To what degree did the Fellow achieve his/her research objective?
H7	Did you experience any problems in hosting the Fellow?
H8	What is your evaluation of the overall program?
H9	Do you intend to continue collaborative research with the Fellow after his/her fellowship ends?

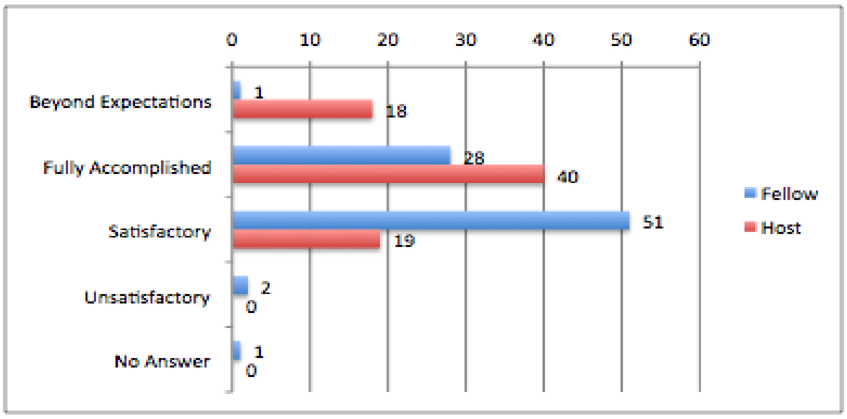

Figure 2. Evaluation of whether the initial research objectives were achieved (questions F8 and H6) (%)

We also gauged professional development by the responses to question F10 (Was this research experience in Japan useful in your professional development?). Ninety-nine percent of the Fellows answered "yes." The question was followed by four explanations from which the participants could choose: knowledge or information acquired during the program, contacts established with Japanese collaborating researchers, international research experience, and experience of living in a foreign country. As most people marked all three explanations, as shown in Figure 3, we assumed that every aspect identified was useful to the Fellows' professional development.

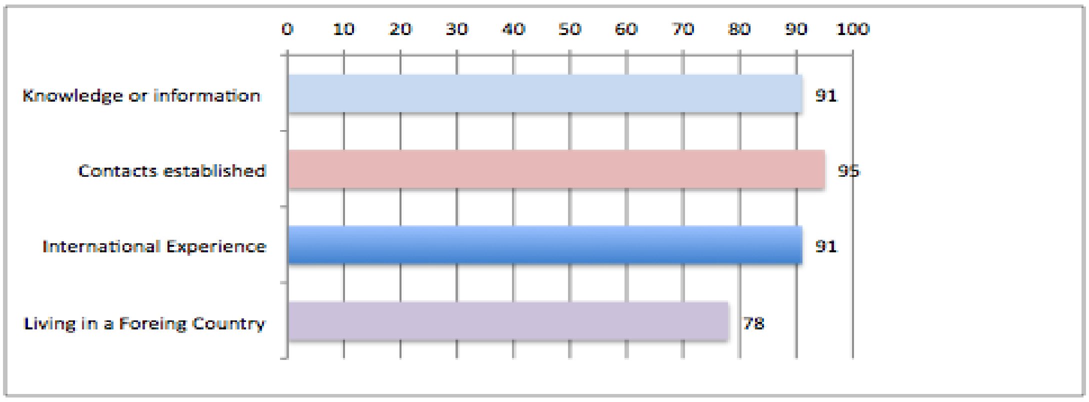

Figure 3. Professional development (question F10) (%)

We next looked at international collaboration. Questions F7 (How often did you exchange research opinions or ideas with Japanese colleagues?) and H5 (How often did you exchange research opinions or ideas with the Fellow?) represent the frequency of oral communication between Fellows and Japanese researchers. As shown in Figure 4, both Fellows and host researchers, including Japanese colleagues, discussed research at least "occasionally" and many replied "often." We note that it is not unusual for host researchers to leave Japan for conferences held overseas during the summer, and Japanese universities set summer holidays in the middle of August; therefore, it is possible that conversations would have taken place more often if there were more opportunities for interaction.

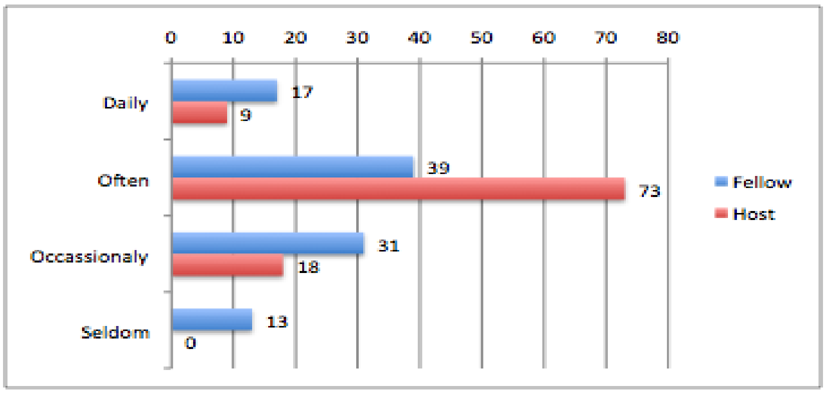

Figure 4. Frequency of research discussions with Japanese colleagues (questions F7 and H5) (%)

Lastly, we looked at the results for scientific contribution. Figure 5 shows the results of questions F12 (What do you think is the possibility of conducting your future research in Japan?) and H9 (Do you intend to continue collaborative research with the Fellow after his/her fellowship ends?), which deal with the possibility of future collaboration between the Fellow and host groups. We cannot make a simple comparison between the two questionnaires because the Fellow's questionnaire did not have a "Have already/am planning to" choice; however, the results were clear that the majority of both Fellows and host researchers were favorably inclined to continuous or future collaborations.

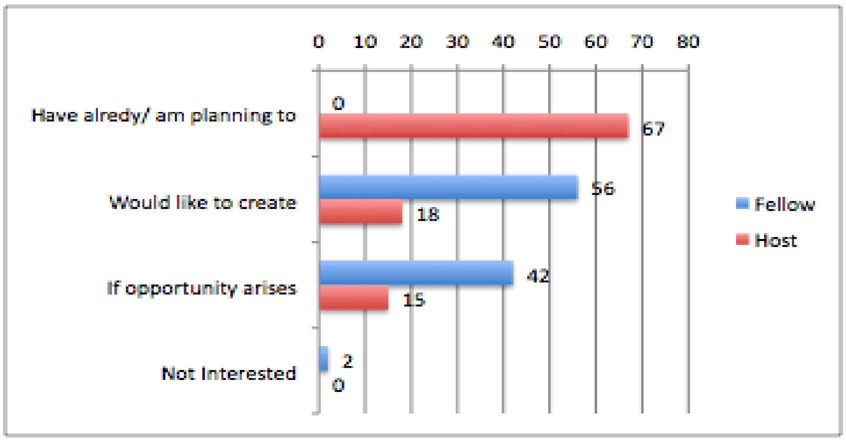

Figure 5. Possibility of returning to Japan (question F12) and intention of continuing collaboration (question H9) (%)

On the other hand, as the results of question H4 (What do you think of setting the fellowship tenure at two months?) show, most (64%) host researchers thought the term was insufficient, while 36% answered "just right," as shown in Figure 6. We found similar results in the comments from both host researchers and Fellows, which we will discuss in the next section.

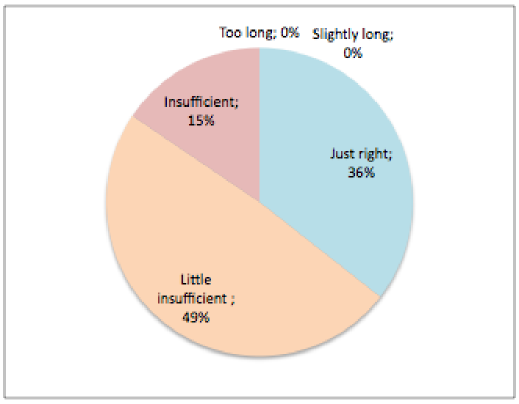

Figure 6. Host researchers' thoughts on the fellowship tenure (%)

We did not focus on the answers to question F9 ("What aspects of the program were the most interesting or valuable to you?") for fear of compromising individuals' anonymity, although the answers provided a detailed picture of the wide range of impressions held by the participants.

4.2. Comments from Reports

The data discussed in this section is based on the final report from all the participants in 2008. The last part of the report offered Fellows and hosts an opportunity to comment on their participation and research in Japan. It is important to emphasize that the comments section was optional, while submitting the report was mandatory. Of the 114 reports submitted, 106 participants (46.5%) of 74 Fellows and 32 host researchers provided comments.

In an attempt to examine the comments, we divided them into three categories, as shown in Table 5. Among all the respondents, 68 comments (29.8%) from 52 Fellows and 16 host researchers fell under Professional Development, 67 comments (29.4%) from 42 Fellows and 25 host researchers fell under International Collaboration, and 33 comments (14.5%) from 12 Fellows and 21 host researchers fell under Scientific Contribution.

Table 5. Achievements represented in the comments in the final report

Categories	Comments
Professional Development	*Fellow C*: "The experience of working in a foreign laboratory and the unique opportunity to collaborate with some of the leading scientists in the field of geochemistry has been a real honor for me." *Fellow F*: "During each visit to other laboratories and facilities throughout Japan, discussions were carried out on the differences in research approaches between American and Japanese laboratories, as well as how the culture and background of each geographical area impacts the respective research process. Discussions and exchanges of ideas have the potential to lead to numerous future collaborations, and many new ideas for future research directions have been created. This trip has proved fruitful not just based on meeting the stated research objectives, but also in better understanding the research culture in Japan." *Fellow G:* "This program allowed me to gain insights and perspectives I would have been unlikely to experience at my home university. In the short term, I intend to continue pursuing several of the results achieved this summer. The product of this will be joint publications with Japanese researchers." *Fellow H*: "At the end of two months, I am now proficient in using the microscope and analyzing images collected with it. I also have a much clearer idea as to what the technology's capabilities and limitations are."

	Fellow I: "This being my first international research experience, I was truly overwhelmed by the friendship, professionalism, and quality of research shared with me. My time here helped me grow in every positive way." *Fellow L*: "The program was one of the most meaningful experiences of my academic career and exposed me to a non-Western perspective on science." *Fellow Q*: "I improved my experimental skills and have had access to experimental equipment not available in Paris, such as an optical parametric amplifier and a two-color pump-probe measurement. I also had the opportunity to give a seminar in order to present my experimental results about spin physics in InAs/GaAs quantum dots. [Professor's name], who is internationally recognized as a leader in non-linear optics in semiconductors, proposed that I attend an international conference in Japan to present my research during the poster session, as well as to visit [university name], which has developed many experiments to study Terahertz physics." *Fellow V*: "Overall, my research experience in Japan was very rewarding, both personally and professionally. Although I did not accomplish all of the goals I had set out for the summer, the program allowed me to branch out and work in a new and exciting field of application that is of definite interest to myself and machine learning. …Finally, performing research in an international setting was a very eye-opening experience; one which I believe will have a positive impact on my future academic career." *Host of Fellow E*: "I am sure that her experience will be beneficial for her career development and enforce a Japan-U.S. scientific exchange and interactions as a member of the next generation of international science professionals."
International Collaboration	*Fellow A*: "I certainly plan to continue this work after my return to the U.S., in collaboration with my new colleagues at [institute name]. I hope to have the opportunity to work in Japan again in the future." *Fellow D*: "I've really enjoyed spending time with fellow researchers from around the world. Through the Summer Program I was able to make meaningful professional contacts in Japan and the U.S." *Fellow E*: "This program has really helped opened my eyes to the international scientific community." *Fellow G*: "In the long term, I believe that I have forged relationships this summer that will turn into lasting collaborations. While I certainly look forward to returning to Japan, I also anticipate some day in the future when I can host Japanese researchers back in the United States." *Fellow L*: "Additionally, the networks I have formed during my time in [lab's name] have opened the door to exciting future collaborations." *Fellow N*: "My time in [professor's name]'s lab has given me a unique opportunity to further my research and collaborate with world leaders in the field of molecule-based magnetism. It has been a fantastic experience, both scientifically and culturally, and I hope it is the beginning of a long and fruitful collaborative relationship." *Fellow O*: "I made many interesting contacts with great researchers in my field, and we exchanged interests in many interesting discussions." *Fellow P*: "Two months is a very short time in research, but it is a perfect amount of time to try out a new idea or a theory in a new environment with different expertise and an alternative viewpoint. We intend to pursue this research in the future and also pursue a side project with bone marrow stem-cell treatment for skin disorders." *Fellow T*: "Besides experiencing the academic and research environment in Japan, I was able to establish contacts not only with Japanese academics but also with researchers from other participating countries of the summer fellowship as well." *Host of Fellow M*: "While the summer program is short, [Fellow's name] has been working diligently and making a lot of progress in his research. We also had a lot of discussions and identified challenging research topics in which we can continue to cooperate in the future."
Scientific Contribution	*Fellow J*: "Both my supervising professors and the other students in my lab were very helpful, and their assistance made it possible to achieve significant results in the limited time available." *Host of Fellow C*: "He has worked hard and observed data that are very important in the field of isotope geochemistry." *Host of Fellow E*: "[Fellow's name] was a very energetic, highly motivated individual. She conducted herself with the utmost courtesy and respect here in Japan, and I think she has been able to contribute greatly to our on-going

	project on Yakushima with her study design integrating well into the overall focus of our research.”
	Host of Fellow H: “One of the excellent outcomes of this program is that a new collaboration has been established. The experiments planned were highly challenging, but we have obtained highly exciting initial results, which can be continued in the collaboration between [name of U.S. doctor] and my laboratories.”
	Host of Fellow K: “She has eagerly studied the research subject and obtained significant results. Her work is greatly helpful and important for our project. Her single-minded devotion to the study has impressed the graduate students in our laboratory.”
	Host of Fellow R: “His STM study on binary molecular assembly has been done as a series of on-going collaborations between [German institute name] and [Japanese institute name]. He found a new combination of molecules to form well-mixed arrays on the surface of Cu (100). This work made a great contribution to our collaboration and created an opportunity for further experiments.”
	Host of Fellow S: “The visit of [Fellow’s name] profited the entire research team in the department both on academic and personal levels. Interesting discussions arose from [Fellow’s name]’s research on the nanocomposite microstructure manufacturing method. Also, the interactions with the students were respectful and friendly.”
	Host of Fellow W: “Even in a short visit, [Fellow’s name] made some fruitful experiments; some of the preliminary results were presented in an International Conference held in Sendai. His presence truly stimulated Japanese students through daily laboratory activities including academic discussions, field experiments, and gate-ball games. I believe the program was very fruitful for both countries’ students.”

From the results in Table 5, in the category of Professional Development, the Fellows felt the program was useful for their career development, as evidenced by Fellow L’s remark: “The program was one of the most meaningful experiences of my academic career and exposed me to a non-Western perspective on science.” The comments from the host researchers (e.g., Host of Fellow E) gave the same impression. Second, in the category of International Collaboration, as Fellow T remarked, “I was able to establish contacts not only with Japanese academics but also with researchers from other participating countries of the summer fellowship as well,” and host researchers (e.g., Host of Fellow M) offered similar comments. Third, in the category of Scientific Contribution, a considerably larger number of host researchers than Fellows expressed that the Fellows made a scientific contribution, such as the comment from the host of Fellow C: “He has worked hard and observed data that are very important in the field of isotope geochemistry.”

Therefore, typical comments, as gleaned from interviews and reports, were as follows:

- Professional Development: This program allowed me to gain insights and perspectives I would have been unlikely to experience at my home university.
- International Collaboration: I would like to continue the research project with new colleagues and hopefully invite Japanese colleagues to my laboratory.
- Scientific Contribution: I made a great contribution, producing significant results for the field or very important data for the ongoing project.

Many of the comments noted the insufficiency of the term but did so in optimistic or favorable contexts, as follows:

- “My research goals proved too ambitious for a single summer, and it proved impossible to learn the necessary data-processing techniques, process the data, and develop models all in a single summer” (Fellow A).
- “Although the period of stay was too short to finish something, I believe this program is effective for both students and advisors” (Host of Fellow U).

In addition, the term is intentionally set as a trial shorter period; those who wish to prolong their stay may do so for up to 90 days.

4.3. Evaluation of the Program

In this section, we present a summary of the findings. Participants considered the program to be effective at providing an opportunity to build professional development, facilitating international collaboration, and creating scientific contributions, while they thought that the term was slightly insufficient.

Particularly with regard to international collaboration, the Fellows built networks among Japanese researchers and participants from other countries, thus obtaining interdisciplinary perspectives through the program, as evidenced by Fellow D's remark: "I've really enjoyed spending time with fellow researchers from around the world." Bringing together researchers with different knowledge and backgrounds could facilitate an exchange of ideas, thereby creating a breeding ground for innovative work as well as providing another layer of support to those involved in the fellowship (Halsey et al., 2007).

Additionally, as the host of Fellows K, S, and W noted, the visiting young researchers inspired young Japanese researchers-to-be to expand their perspectives. It seems that "in the workplace, knowledge spreads to colleagues, especially those in close contact" (OECD, 2008).

5. CONCLUSIONS

As discussed, the program clearly achieved two goals: (1) it is a legitimate strategy for attracting individuals to the profession and for nurturing the next generation of scientists, and (2) it contributed to the commencement of international collaboration, as it was initially framed to do. It is also noteworthy that many of the Fellows achieved various non-science goals and felt confident in conducting research in a different country for two months.

The evidence accumulated in this paper also provides suggestions for further research. Since there continues to be ambiguity among some descriptions, it is necessary to modify the questionnaire so that the results reveal more precise achievements by improving the choices for each item. Doing so would provide better results to measure the future achievements of the program. In addition, with regard to strengthening the findings, we should explore the impact of the participation of former Fellows (so-called JSPS alumni) and accumulate the questionnaire results obtained from previous years.

In conclusion, providing an opportunity for young researchers to conduct research in a different country promotes their professional development, encourages knowledge exchange, and forms global scientific networks. Although the findings indicated the need to prolong the fellowship term to achieve the initial research goals, we expect that such feelings of insufficiency could lead to future research activities within the networks established through the program. Therefore, we hope that JSPS, as one scientific academy, works toward continuing and formulating such programs, so that it can serve as a springboard for international collaborations in science and technology. This would also benefit the countries that send researchers, because the emigration of skilled researchers and scientists can be beneficial for the creation and diffusion of knowledge in their country of origin (OECD, 2008). In addition, as several other fellowship schemes administered through governmental organizations are currently available, it would be possible to profit from the knowledge and experience of the fellowships that are already being offered, thereby increasing the global stock of knowledge.

5. ACKNOWLEDGMENTS

We appreciated the financial support of KAKENHI, the Grants-in-Aid for Scientific Research (A) No. 20240068 from the Ministry of Education, Culture, Sports and Technology (MEXT). The authors are grateful to JSPS, especially the Overseas Fellowship Division, for their kind cooperation.

THE TEACHING OF SCIENCE AND MATHEMATICS IN ENGLISH: A CRITICAL APPRAISAL

Suan Yoong

Sultan Idris University of Education, Malaysia

(yoongsuan@yahoo.com)

Lee Yuen Lew

Long Island University, C. W. Post Campus, USA

(leeyuen.lew@liu.edu)

ABSTRACT

In a pluralistic society, language and medium of instruction have always generated controversies and debates. The teaching of science and mathematics in English in many developing countries, especially former British colonies is an extension of these debates. Pedagogically speaking, science and mathematics contents are cognitively more demanding and require learning tasks that involve abstract and formal thought. What does research evidence say about learning of STM subjects in English by non-speakers of English? Does the practice of teaching STM subjects in English to non-speakers of English go against scientific evidence about learning? What level of English competency must non-speakers of English acquire before they are proficient enough to use it to acquire the contents of STM or other subjects? What evidence supports that children can manage the transition to switch to the learning of content in a second language (English)? This paper seeks to address these questions by providing a comprehensive review of research findings relating to the acquisition of English as a second language in a multiethnic student population, highlighting issues and challenges faced in managing the transition to the learning of STM or other subject contents in a second language, notably English.

Keywords: *Teaching of science and mathematics in English, second language acquisition, mother-tongue education*

INTRODUCTION

Parents In many developing countries view English as the language that could help their children towards finding employment and consequently upward mobility. Most former British colonies inherited education systems that consciously propagated English as basis for developing the national education policies. With unequal development of vernacular schooling sustained through policies that combined mediated and unmediated acts of rewards and recognitions, English acquired immense economic value and become a lingua franca in interethnic communication in these countries even after years of independence. It is the language of the elite, power, and privileged. Many parents see it as a means for achieving unlimited vertical social mobility. Indeed, English has emerged as the most important international language for trade and commerce in the epoch of rapid globalisation. Books, journals, research or technical papers, and popular writings, notably in science, technology and mathematics (STM), and the Internet are predominantly in English. Given the geometric growth of knowledge and development in information, English has become the worldwide norm to access STM information in the Internet. More than 63 nations have recognized it as the official language (Mackey, 1984:434). In many of these countries, English has also taken center stage and is used in all high domains, notably the government and sociopolitical administration, education, economy, and diplomacy.

As a newly industrialising country that has benefited from a very rapid rate of economic growth, Malaysia requires a large workforce that can effectively access the knowledge and skills in STM to help transform the country into a knowledge-based economy and society by 2020 (Mahathir Mohamad,1991). The decline in the standard of English in Malaysian schools worried government and private sector leaders, who fear that the nation may risk lagging behind economically and loosing competitive edge if they do not respond to the global change of developing a large English-proficient workforce. Improving the standard of English language as well as acquiring cutting edge skills in STM has become a major aspiration of the Malaysian government. Consequently, the Ministry of Education introduced the policy of teaching of STM subjects in English at all levels of schooling based on the belief that this practice will improve both the standard of English language as well as the standards of science and mathematics in Malaysian schools. The policy was implemented in 2004. Although a substantial number of parents supported this controversial policy, oppositions from various quarters were more wide-spread since most Malaysian students are schooled in their mother tongue languages, and are only learning English as a subject formally at the entry level of schooling. After completing a 6-year cycles of implementation and facing wide-spread resistance, the Malaysian government made a round-about turn in its policy and rescinded the policy of teaching STM subjects in English at the primary and secondary school levels with effect from January 2012. The round-about turn in policy again fuels both oppositions and supports from Malaysian parents.

PROBLEM STATEMENT

No one doubts the importance of English, especially as a mean to effectively access the knowledge and skills of science and technology. What is worrying is that, in Malaysia, the switch to teach STM subjects in English ignored the standard practice of curriculum development and readiness for implementation. No study had been carried out to evaluate the effect of teaching STM subjects in English prior to implementation. Research evidences pertaining to the validity of this practice of teaching STM in English were ignored. The dominant rationale is purely market driven based on a commonly prevailing myth hinging on the immense economic value of English language. As Hafriza (2006) justifies:

> “In this age of industrialization and internationalization, we cannot deny future generations the ability to access new frontiers in science and technology simply because of their poor English.” (p. 24)

This commonly prevailing myth had driven many government leaders and administrators into believing that using English as the medium of instruction in schools is the best way to produce an English-proficient workforce, starting as early as possible.

Teaching STM subjects in English at the primary school implies that one is not merely teaching the subject contents but also the target English language system as well to non-speakers of English in a non-English speaking environment. Pedagogically speaking, STM contents are cognitively more demanding and require learning tasks that involve abstract and formal thought. What does research evidence say about learning of STM subjects in English by non-speakers of English? Does the practice of teaching STM subjects in English to non-speakers of English go against scientific evidence about learning? What level of English competency must non-speakers of English acquire before they are proficient enough to use it to acquire the contents of STM or other subjects? What research evidence supports that children can manage the transition to switch to the learning of content in a second language (English)? From a socio-psychological perspective, does the practice of not using a language of instruction that learners understand best goes against scientific evidence about learning? Does the practice transmit the socio-cultural message that one’s own language, culture and experiences have no value in acquiring STM skills?

This paper seeks to address these questions by providing a comprehensive review of research findings relating to the acquisition of English as a second language in a multiethnic student population, highlighting issues and challenges faced in managing the transition to the learning of STM or other subject contents in a second language, notably English. Evaluation studies carried out in Malaysia to assess the impact of implementing the policy of teaching of STM subjects in English are presented.

RESEARCH EVIDENCE

Important facets of intellectual functioning are intimately linked to language development. There is overwhelming evidence from studies in many countries that the learning of basic concepts and intellectual processes in the early stages of a child's development is best established through the language a child understands best, which is usually the mother tongue, before a second language can be used as the learning medium at a later stage (UNESCO, 2008). Whether done through parental choice or otherwise, knowingly or unknowingly forcing a child to accept instruction through a language that one hardly understands goes against scientific evidences about learning, as the following review of research shows.

Language plays a critically important role in classroom learning. Since it is the key to communication and understanding, it is essential that a language that learners understand and speak is used as the language of instruction. It enables the children to participate in the meaningful learning processes according to their evolving capacities and student learning can be accurately assessed. When students can express themselves, teachers can diagnose what has been learned, what remains to be taught and which students need further assistance. When an unfamiliar language is used in instruction, cognitive learning and language learning are confounded, making it difficult for teachers to determine whether students have difficulty understanding the concept itself, the language of instruction, or the language of the test. Extremely high educational demands are required of these learners and consequently few of them have sufficient knowledge of the language of instruction to support them through schooling. Indeed, switching to the learning of content in another language through a language of instruction that a learner hardly understand provides a double set of challenges: not only does one has to learn a new language but also to use that language to learn new knowledge. "It would give rise to a great deal of confusion, producing a lack of clarity of thought and a slowing down of those processes that utilize linguistic mediators" (Lambert, 1977) and it takes years before students can discover meaning in what they are "reading" (Baker 2001; Cummins, 2000; CAL, 2001). While there is evidence that many children did manage the transition to the mainstream education in a second language, they, however, represented the top 10 to 15% of the higher ability students with strong family background or support.

That a child learns better and more productively if learning is done in a language that one understand best is an axiomatic principle of education reiterated by UNESCO since 1953 (UNESCO, 1968/1953). Research has also served to confirm the arguments in support of mother tongue education programs (UNESCO, 2003). Reviews of research put the issue in clearer perspectives, and substantiated the critical connection between primary language skills and academic success (see for example, Dutcher, 1995; 2004; Constantino, 1999; Walters, Davis & Morren, 1999; Thomas and Collier, 1997/2002; UNESCO 2008; Cummins, 1979; 1989; Cummins & Swain, 1986; Skutnabb-Kangas 2000).

The research conducted by Thomas and Collier (2002), in particular makes the strongest empirical argument for mother tongue education. The sheer scope of the longitudinal study, which involved more than 60,000 students in 25 school districts in every region of the USA, makes the results and conclusions difficult to ignore. By following non-English speaking children through grade 11 in selected US schools and by comparing the results of six different levels of educational support in the mother tongue, Thomas and Collier presented a convincing picture of the differential outcomes of these six different approaches: students with four to seven years mother tongue educational support in a quality bilingual program sustain academic achievement and outperform monolingually-schooled students in the upper grades, making a forceful case that language is, indeed, a critical mediating component in effective long-term education.

While Thomas and Collier made no claims about the implications of their research for education in developing countries, they did propose an explanatory model for their findings which can be readily extended to educational experience in developing countries. Indeed, pieces of empirical evidence from studies carried out in Africa, Asia and Latin America do support the educational advantages of mother tongue education: learning to read in their own language provides learners with a solid foundation for learning to read in the second language, outperforming those taught to read in a second language in immersion education (UNESCO, 2008).

In contrast, research with indigenous and minority learners from all over the world also provided plenty of negative evidence suggesting that immersion education models are ineffective, wasteful in terms of human resource development, marginalising language minority children, and resulting in high dropout and illiteracy rates (Macnamara, 1966; Cummins, 1981, 1984; Jeffcoate, 1984; Cummins & Swain, 1986; Cardenas, Robledo, & Waggoner, 1988'; Saville-Troike, 1991; Musker 1993; Baker, 1993; Samuels 1995; Moss & Puma, 1995; Hartshorne 1995; Alexander 1998; Brint, 1998).

Research in the English-speaking countries specifically documented the slowing down effect of the learning process when minority students switch to the learning of content in a second language. Studies show that language-minority students in the English speaking countries in the West are 1.5 times more likely to drop out of school than native speakers (Cardenas, Robledo, & Waggoner, 1988). In learning English as a Second Language (ESL), minority students tend to receive lower grades, are judged by their teachers to have lower academic abilities, and score below their classmates on standardized tests of reading and mathematics (Moss & Puma, 1995). In U.S. schools where all instruction is given through ESL, non-native speakers with no schooling in their first language take 7-10 years to reach age- and grade-level norms (Cummins, 1981). Immigrant students who have had 2-3 years of schooling in their first language (in their home countries) take at least 5-7 years to reach age- and grade-level norms (Cummins, 1981; Cummins & Swain, 1986). Non-native speakers schooled in a second language for part or all of the day, typically do reasonably well in early years: from fourth grade. However, when academic and cognitive demands of the curriculum increase rapidly, students with little or no academic and cognitive development in their first language fail to maintain positive gains. Canadian Inuit students taught in English reach only Grade 4 level after 9 years of schooling (Wright & Taylor, 1995; Wright, Taylor & Macarthur, 2000) and English is the greatest barrier to successful classroom learning for Aboriginal children in Australia (Zeegers, Muir & Lin, 2003).

Studies by Baker (1993) showed that learners using English as a second language and not their first language (mother tongue) as a medium of learning lag behind their peers, who are taught in first language, in areas such as mathematics and science. According to him, their second language skills are insufficiently developed to enable them to think mathematically and scientifically in their second language. By using a second language from too early on, the practices are stunting the development of the learners' own language, impeding the development of their cognitive and academic abilities, promoting negative attitudes towards the first language, and resulting in low achievement in high conceptual demand subjects such as science and mathematics. Segalowitz (1977) points out S&M subjects are inherently more difficult for most learners, even studied through their first language (mother tongue). They are cognitively high demanding and require learning tasks that involve abstract and formal thought. Many students already found S&M learning in their first language (mother tongue) inherently difficult. It would be significantly more difficult for students learning them through the second language (English), especially at a very early stage. If forced to do so, the consequence can be disastrous for those who could not cope with it. Cummins (1984) observes that most children characterized as learning disabled or learning disordered encounter language and academic problems, which are usually confined to context-reduced cognitively demanding situation.

As Alvarez (1991) observed in the Philippines, ‘English is a poor substitute for an indigenous language which is used by a child in and outside the school environment. The upper 10-15% educated and intellectual group will be able to handle and be competent in the two languages. But the greater bulk of the population will need scientific information that is popularized using the native language’. A student can master a second or a third language over the years of schooling, but the time period required varies and depends on the individual’s ability and effort. Only a small percentage of students, most of who are from the upper or middle class with strong background support, can master a second or third language at the early phases. The rest requires a much longer time to master a second language, but many of them are not successful at all during their entire schooling period. Such a form of education is selective & elitist, with high dropout rates, resulting in a generation of semi-illiterates in both the first and second language.

“The Irish findings relating to the teaching of other subjects through the medium of a second language are particularly discouraging. For it seems that the teaching of mathematics, at least through the medium of the second language does not benefit the second language, while it has a detrimental effect on children’s progress in mathematics” (Macnamara, 1966). In South Africa, the practices of using a second language (English) from too early on are stunning the development of the learners’ first language or mother tongues, impeding the development of their cognitive and academic abilities, promoting negative attitudes towards the first language, and resulting in low achievement in high conceptual demand subjects such as S&M (Saville-Troike, 1991). The abrupt switch from the mother tongue to a European language as the medium of learning in Africa has resulted in high failure rates and dropouts (Lanham 1978; Musker 1993; Alexander 1997; Hartshorne 1995).

In Peninsular Malaysia, five years after schools began teaching of science and mathematics in English schools, Ishak *et. al* (2009) tested five thousands over students from a mix of urban, rural and vernacular schools on mathematics, science and English language. The tests were made up of modified past-year public examination questions. Some were taken straight out of textbooks. The results revealed poor scores in these subjects. For example, some 1,700 year five primary school students had a mean score of 7.89 out of a maximum 20 for mathematics, a mean of 4.08 out of 14 in science, and a mean of 11.87 out of 31 for English. The study showed that the majority of students still find it hard to follow mathematics and science lessons in English. A number of local survey studies (Lim & Wun, 2003; Lim & Chee, 2005; Hamidah *et al*., 2005; Tan, 2006; Lim, Fatimah & Tang, 2007) revealed similar perceptions among the teachers themselves, and that most of the current primary and secondary S&M school teachers had only minimal proficiency in English and their lack of command of English hinders their ability to teach S&M effectively in English. The situation in the premier or elitist schools is much better, though. In rural schools, the majority of the students have no supporting English language learning backgrounds and most of them are only learning ABC formally at the entry level of schooling.

Taken together, all these are indicative of the destructive nature of a poor mastery of the language medium if that language is used as medium of instruction. As a result, children who lack the linguistic skills, but are otherwise intelligent and scholastically capable, may not be able to realize their full academic potential. Baker (1993) attributes the low academic achievement among minority children in USA and the UK to their poor mastery of English.

Jeffcoate (1984) maintains that minority pupils from working-class parentage do not enjoy equal opportunities in education due to their lack of competence in the language medium, which affects their educational attainment. Brint (1998) is of the view that children cannot learn unless their basic language skills are adequate.

The strength of utilizing student's fluency in their own language to the fullest in the formative years of education lies in enhancing student self-esteems, and motivating them towards establishing the habit of academic success since the students will perceive that their home and community culture, parents and relations are accepted by the mainstream school culture, thus minimising cultural shock (Gudschinsky, cited in Cohen, 1978). As a UNESCO document puts it:

> "Psychologically, it is a system of meaningful signs that in his mind works automatically for expression and understanding. Sociologically, it is a means of identification among members of the community to which he belongs. Educationally, he learns more quickly through it than through an unfamiliar linguistic medium" (cited in Todd, 1983:165)
>
> Otherwise, the home language & culture may seem disparaged. In these circumstances, the students will find schooling emotionally stressful and hence, vulnerable to the loss of self-esteem and status. This, in turn, may affect the child's motivation and interest in schoolwork and thereby affect performance (Baker, 1993).

THE WAY FORWARD

What constitutes the best way to assist students to learn ESL is hotly debated. There is probably no one best way to teach ESL to learners. Different approaches are necessary because of the great diversity of conditions faced by schools and the varying experiences of ESL learners with literacy and schooling in their first language (August & Hakuta, 1997). It is important to understand the consequences of various program designs for students learning English. Collier (1995) asserted that it is a mistake to believe that the first thing students must learn is English, thus isolating the language from a broad complex of other issues. In particular, one must be aware of the culturally Western-oriented tradition of S&M teaching-learning, which is loaded heavily with culturally-biased, notably towards English technical and non-technical terms or phrases. For students whose first language is not English to learn S&M successfully, they need to mediate or negotiate cultural borders, i.e. move back and forth between the indigenous and the English "scientific" culture (Jegede & Aikenhead, 1999). The teachers' role is to help the students to deal with the cultural conflicts that might arise when a student "crosses cultural and linguistic borders" from the use of the first language to English.

Research in English language learning showed that context embedded basic interpersonal communicative skill (BICS) in English can be easily acquired within two years (Cummins, 1979). BICS involves context-embedded and cognitively undemanding face-to-face communicative skills, which includes the ability to handle complex conversation using contextual cues such as paralinguistic feedback from other speakers (e.g., gestures and intonation) and situational cues to meaning (Ovando & Collier, 1985). In contrast to BICS, a period of seven to eight years is needed to acquire the cognitive-academic language proficiency (CALP) of a certain language (Cummins, 1979). CALP involves the use of language that is context-reduced and highly demanding cognitively (Ovando & Collier, 1985). It also includes academic tasks in abstract thought and formal written language. Context reduced communication relies heavily on linguistic cues alone and involves abstract thinking.

Many studies support a balanced literacy program as appropriate for students whose first language is not English to learn the English language and subject matter such as S&M. Various approaches may be used to achieve this aspiration. Both cognitive development and academic development in the first language have been found to have positive effects on second-language learning (Bialystock, 1991; Collier, 1989, 1992; Garcia, 1994; Genessee, 1987, 1994; Thomas & Collier, 1997; 2000). Moreover, literacy skills related to decoding tasks of reading have been found to transfer between languages (Bialystock, 1991; Goodman, Goodman, & Flores, 1979; Hudelson, 1987; Mace-Matluck, 1982). Specifically, learning to read and write in the first language supports success with reading and writing in the second language (August & Hakuta, 1997; Cuevas, 1997; Roberts, 1994).

The most reasonable strategy is to continue the practice of learning S&M subject matters in the student's most proficient language while simultaneously assisting the learner to acquire basic proficiency (CALP) in the second language so as to use it to learn STM and other subject matters, *if and when necessary*. Using English to teach STM subjects at an early stage will only work with students from English-speaking background or who have background and family support, especially the high ability students. Special programs may be set to cater to the needs of these students but this practice will risk creating elitism in the school. What we need is to up-grade the teaching of English as a second language in the schools, and certainly not to complicate the issue by implementing the teaching of S&M in English to all students, especially at an early stage. Given this scenario, the Malaysian Ministry of Education's reversal of the policy of teaching S&M in English, particularly at the primary school level is a positive move that should be lauded.

LEARNING STYLE PREFERENCES AS PREDICTOR OF PERFORMANCE IN SCIENCE IN PUBLIC JUNIOR SECONDARY SCHOOLS IN GHANA

Thomas Young Tachie

Department of Science Education.

University of Education,

Winneba, Ghana.

tachieyoung2001@yahoo.com

ABSTRACT

Despite the groundswell of literature on learning styles and academic performance, little research has been carried out on learning styles in Ghana. This study examines the learning style preferences of students in the public Junior High Schools and their influence on students' performance in science. An exploratory survey was conducted using two instruments, Tachie-Young Learning Styles and Performance in Science Test. A sample of 1334 JHS students responded to the survey. The Statistical Package of Social Sciences (SPSS) was used in the analysis of data input. Data were statistically analysed using descriptive, correlation statistics, and multiple regression techniques. The dominant learning style preference of students in the JHS is auditory (65%), kinesthetic (25%) and visual (10%). Female students were more auditory in their learning style preferences than male students while the male students were more visual in their learning style preferences than the female. Jointly, 12.7% of the variance in performance is accounted for by grade level, age, sex, and auditory learning styles of students. The dominance of auditory style preference in the present study could be attributed to cultural influences where much is learned by auditory means at home and further perpetuated by traditional teaching practices.

Keywords *: Learning styles, Junior High School (JHS), JHS2&3 students (grade 8 and 9 students), Basic Education Certificate Examination (BECE).*

INTRODUCTION

Scientific experiences in Junior High Schools in Ghana are expected to cultivate in students an interest and love for science that will urge some of them to seek further studies in science as preparation for careers in science (Ministry of Education, Science and Sports, 2007). However, science teaching in the JHS has been characterised by negative features that have the potential of driving off many students. Teachers of science at the JHS, oftentimes expressed concern that even though they are teaching according to the dictates of the syllabus, they are unable to significantly impact on students' performance in their final Basic Education Certificate Examination (BECE). The general observation is that students' performance had been poor and quite a number would wish to stay out of science classes. At the national level, over 40% of the students could not make a passing grade (1-5) required for admission into second cycle institutions. At the international level, Ghanaian students' maiden participation in Trends in International Mathematics and Science Study (TIMSS) in 2003 was abysmally poor (Anamuah-Mensah, Asabere-Ameyaw & Mereku, 2004). This performance placed Ghana at the 45th position out of the 46 participating countries in the study in 2003. Ghana's performance which did not change in 2007. The general poor trend in the performance of students, especially in science, continues to be of concern to educators in Ghana.

The question is: why would students not do well if the teachers pride themselves to have adequately prepared students as well as taught the subject content to make students succeed? If teachers find appropriate ways of helping students, then students will gain confidence, be motivated to create, and express themselves (Rosenfeld & Rosenfeld, 2007). There is therefore the need for teachers to look at other factors that contribute to students' performance. Learning styles preferences of students could be one significant factor that teachers need not overlook. Whatever are the merits or demerits of learning styles they eluded the Ghanaian academic community, which this study sought to explore.

LITERATURE REVIEW

Since the emergence of learning style research around 1892, majority of the research appeared in the 1940s (Keefe, 1987). By 2006, over 650 books had been published, 4,500 articles written in professional publications and over 26,000 websites available for measuring and addressing learning styles (Howles, 2008). Learning style is basically, the preferred way to learn and the way a person learns best. Merriam and Caffarella (1991) defined it as an individual's characteristic way of processing information, feeling, and behaving in learning situations. James and Gardner (1995) defined learning style as the complex manner in which, and conditions under which, learners most efficiently and most effectively perceive, process, store, and recall what they are attempting to learn. Learning styles, as defined by Guild (1994), are conceptual, behavioural, cognitive, and affective patterns that are displayed over time and task. Students therefore possess certain basic characteristics that serve as indicators of how they learn. For the purpose of this study, three sensory learning styles, auditory, visual and kinesthetic are examined.

AUDITORY STYLE PREFERENCES

Students with auditory style preference learn best by hearing and remembering information they hear. They are distracted easily, either by noise or music. These individuals talk to self aloud and actively participate in class discussions and would prefer to tape and then listen to lectures. To recall information, they use mnemonic devices. They enjoy listening, but cannot wait to have a chance to talk themselves. These students respond well to lecture and discussion (Barbe, 1979). Often they find themselves talking to those around them. In a class setting when the teacher is not asking questions, they must find a way to express their emotions verbally (Cuyamaca College, 2004). Out of school too, they remember things said to them and make the information their own. They may even carry on mental dialogues and determine how to continue by thinking back on the words of others.

VISUAL LEARNING STYLE PREFERENCES

Students with visual learning styles learn by seeing. They think in pictures and have vivid imaginations. They have greater recall of concepts that are presented visually (Barbe, 1979). Pictures and images help them understand ideas and information better than explanations. A drawing may help more than a discussion about the same. When someone explains something to them, they may create a mental picture of what the person talking describes. They prefer to watch a speaker talk, as well as listen to what is said and are able to work from the general to the specific. They like to receive information from many sources when learning new concepts. They see the "big picture", (the forest) before seeing its part (the trees) and like to "see" things to understand them. They find verbal instructions difficult as their mind tends to wander during lectures. They like to read, and generally are good at spelling. They doodle frequently but organize well. They have good handwriting and take notice of details.

Kinesthetic Learning Style Preferences

Kinesthetic describes a learning style which involves the stimulation of nerves in the body's muscles, joints and tendons. Kinesthetics try things out, touch, feel, and manipulate. They express their feelings physically (Stronck, 1980). They gesture when speaking; they are poor listeners, and lose interest in long speeches. These students learn best by doing. They need direct involvement in what they are learning. More than thirty percent of students may have a kinesthetic/tactile preference for learning (Barbe, 1979). Often, they do not thrive in traditional schools because most classrooms do not offer enough opportunity to movement or touching. Most assessments group kinesthetic and tactile styles together, though they mean different things. Their similarity is that both types perceive information through nerve ends in the skin, as well as organs through muscles, tendons, and joints. Kinesthetics are usually well coordinated with a strong sense of timing and body movements. In some cases, they often wiggle, tap their feet, or move their legs when they sit. Some of these children were often labeled as hyperactive before this learning style was discovered (Dominican University of California, 2008).

Learning Style Preferences and Performance in Science

Learning styles have been found to have a positive relationship with academic performance, as measured by grade point average (Torres & Cano, 1994). A research conducted by Dawson-Brew (2000), among 75 undergraduate students at the University of Cape Coast, Ghana, found that 30(39%) of the students possess field-dependent learning style preferences, 22(29%) possess field independent and 25(32%) as having a combination of the two learning style preferences. Significant differences in performance of students were found among the three levels of preferences in a pre- and post-test scores. The findings, though, lend credence to the existence of learning styles preferences among Ghanaian students does not extend to students in Junior High Schools in Ghana.

Dauve, Garton and Thompson (1999) investigated if ACT, high school core grade point average, and high school class rank were predictors of academic performance and degree completion at the University of Missouri. Field-independent learners exhibited a tendency for greater academic performance than their field-dependent peers. The best predictor of students' academic performance, as determined by cumulative college GPA, was their high school core GPA. Learning style was not a predictor of students' cumulative GPA.

Park (2000) found that among Southeast Asian students there is no statistically significant difference among high-, middle-, and low achieving group in their favourable preferences for learning styles such as auditory, visual, kinesthetic or tactile learning styles. These Southeast Asian students show either major or minor preference for group learning compared with East Asian students (Koreans and Chinese) who showed negative preference for group learning (Park 1997). However, the subjects of Park (2000) study were Southeast Asians immigrants: Cambodians, Hmong, Lao and Vietnamese whose profile is different from the Ghanaian JHS students under study.

Influence of Culture on Learning Styles

Culture as a commonality of customs and rules shared by a certain group of people sets a complex framework for learning and development (Trommsdorf & Dasen, 2001). Also the systematic differences found in the way in which classrooms function in different parts of the world can be largely linked to cultural differences (Crahay, 1999). These then draw a firmer connection between culture and classroom practices. Lattuca (2002) contends that learning cannot be separated from the contexts in which it occurs, and that cognition and learning are activities that occur through social interaction. This socio-cultural view also gives equal weight to the influence of both the immediate setting as well as to the larger one in which it is embedded shifting the focus away from the individual and allowing for a multi-dimensional view of learning. These imply that there may indeed be culturally related differences in the learning style preferences of Junior High School students in Ghana as compared to either Western or Asian countries.

Influence of Age and Sex on Learning Styles.
Perceptually, the younger the children, the more kinesthetic they are and in elementary school, less than 12 % are auditory and 40 % are visual (Dunn &Dunn, 1992, 1993; Dunn, Dunn & Perrin, 1994). The older the children become the more visual and auditory they become. Additionally, they reported that as a group, females are more auditory than males; males are more visual and remain more kinesthetic than females. However, Cook (2000) examined the learning styles of freshmen entering college and their first year academic achievement. Though considerable diversity was found among four learning styles of the students, gender across the distribution of the four learning styles was quite similar. There was no significant interaction between learning style type and gender. The four learning styles were accommodator, diverger, converger and assimilator. The current study however investigates auditory, visual and kinesthetic learning styles of Ghanaian students.

METHODOLOGY

Subjects
The population of the study was all Junior High School students in public schools in the Greater Accra Region of Ghana, comprising 919 public JHSs and 151,333 students. A three-stage cluster sampling procedure was used to select the study sample of (n= 1334) students made up of 992 JHS2 students of which 471 were males and 521 females. The JHS3 students were 893 of which 428 were males and 465 females. The average age of students was 16 years. Students were drawn from diverse spectrum of socio-economic background.

Instrument
For this study the Tachie-Young Learning Styles Instrument (TYLS) based on VAK (an acronym for Visual, Auditory and Kinesthetic) inventory developed by Neil Fleming (1997) is chosen as it assesses basic characteristics of relatively young learners. Items are based on how learners use their senses of sight, hearing and touch. Auditory, visual and kinesthetic learning styles are seen as avenues of preferred perception (Eiszler, 1983) are concepts that could easily be explained through daily life experiences by students themselves and by teachers. The instrument has same dimensions as the Swassing-Barbe Modality Index which categorizes learners as preferring visual, auditory, or tactile/kinesthetic styles (Barbe & Swassing, 1979). Items of the TYLS instrument directly relate to the type of academic prerequisites and instructional activities typically assigned in classes which involve students' perception and processing of information. For example, the following statement "I find it easiest to learn something new by": listening to someone explain, watching a demonstration or trying it myself, allows for a direct connection with their ability to either listen, visualize or practise.

Face and content validity of the instruments were enhanced through assessment provided by a Professor in science education and three PhD students who were familiar with the purpose of the survey. They examined the items of the survey and were satisfied that they were representative samples of learning behaviour that was under investigation. Suskie (2007) contends that because all sensory modality instruments address sensory perceptions, they make intuitive sense and have high face validity. As a result of the review, language was moderated to suit the level of JHS students. Respondents were free to ask questions for clarifications. They were assured anonymity which presumably made them answer the items on the instrument with honesty. These measures were adopted to ensure that reliable and valid data were obtained.

The TYLS instrument is self-administered and comprises of 20 items that are designed to identify three major learning styles: auditory, visual and kinesthetic. Each item has three alternatives (A, B, or C) which describes a characteristic corresponding to each of the three styles. The dominant learning style of an individual is determined by adding up the number of As, Bs or Cs one selects. As refer to Auditory, Bs to Visual and Cs to Kinesthetic. Students were required to award marks out of 10 to each of the preferences. The scores indicate rating of a student's preference. For example, a tick (√) or circling of B would indicate an inclination for visual learning. Awarding marks out of 10 to each alternative indicates how much one prefers one option over the other(s). An example is shown in Table 1 below.

Table1: Illustration of scoring of items on the TYLS
In my free time, I would rather prefer to:

A	**talk with a friend**	**3**
B√	**watch cartoons on TV**	**6**
C	**move about and play**	**1**
		10

The second instrument, Performance in Science Test (PiST), made up of 46 items examined common themes. Some of these were on matter, living things, energy, water, soil, solar system and measurement. Internal consistency estimates of reliability gave a Cronbach's alpha values of 0.53 for Auditory, 0.46 for Visual, 0.43 for Kinesthetic. This compared to 0.41, 0.53, 0.54, and 0.55 determined by Van Zwanenberg et al., (2000) for a sequential-global dimension for measuring learning style preferences of students using the Index of Learning Styles (ILS) instrument. The Performance in Science Test (PiST) Scale had Cronbach's alpha value of 0.82. Tuckman's (1999) suggests that an alpha of 0.75 or greater is acceptable for instruments that measure achievement and .5 or greater is acceptable for attitude tests while Duvall (2008) also asserts that a reliability of 0.70 or better is desirable for classroom tests.

Procedure
The Tachie-Young Learning Styles Instrument (TYLS) and the Performance in Science Test (PiST) were administered to participants in each of the selected schools. All the JHS2&3 students present on the day of the visit took part in the exercise. Instructions on the questionnaires were simple but time was made available to explain the procedure of scoring to the participants.

RESULTS

Learning style preferences of students
The students' dominant preferences were 772(65%) kinesthetic 302(25%) and 114(10%) for visual. Figures1 and 2 show distribution of students' learning styles and multimodality of individual student's styles respectively.

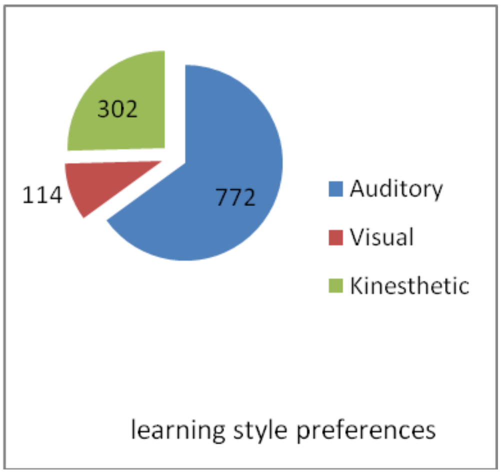

Figure 1: Distribution of students' learning styles

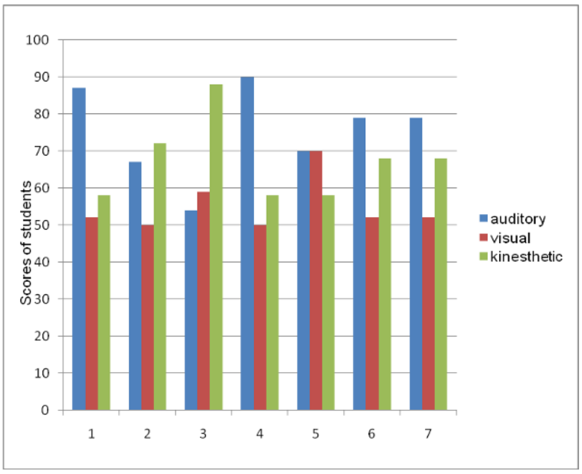

Fig. 2: Multimodality of individual students' styles

Students were more auditory in their style preferences and were neither exclusively, auditory, visual nor kinesthetic in their learning styles. Correlation between each pair of learning style preferences (Table 2) was moderately negative; when one learning style increases the other decreases. For example, the correlation between auditory and kinesthetic showed a negative correlation, *(r =0-.566)* that was statistically significant, meaning increased auditory lowers (decreases) kinesthetic styles of the individual student.

Table 2: Pearson's Correlation among Auditory, Visual and Kinesthetic Learning Styles

	Auditory	Visual	Kinesthetic
Auditory	**1**	**-.472***	**-.566***
Visual	**-.472***	**1**	**-.265***
Kinesthetic	**-.566***	**-.265***	**1**

* Correlation is significant at the 0.05 level (2-tailed).

Learning style and performance in science

Using multiple regression techniques, results show that from the three predictor variables (auditory, visual and kinesthetic) the effect on performance in science is significant for only auditory *F(1, N = 1153) = 11.530, p=.001*. The coefficient of determination R^2 *(.010)*, indicates that about 1.0% of the variance in the science score is predicted by the predictor variable, auditory. Figure 3 shows a graphical relationship between the learning style preferences and performance in science of first seven individuals of the study.

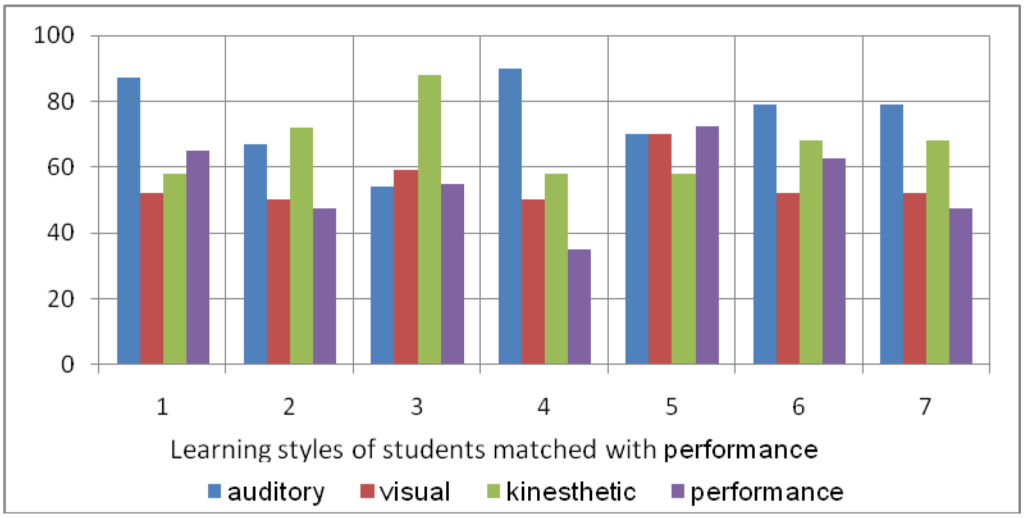

Figure 3: Graph showing learning style preferences and performance in science

Age, Sex and Grade Level on Learning Styles

The variable that significantly affects auditory and visual learning style preferences is sex whereas grade level and age significantly affect kinesthetic learning style preferences. Female students were more auditory in their learning style preferences (M = 77.65, SD = 14.70) than the male students (M = 75.81, SD = 15.77), $t(1184) = -2.08$, $p = .038$. The male students were more visual in their learning style preferences (M = 56.71, SD = 11.60) than the female students (M = 54.69, SD = 11.96), $t(1182) = -2.94$, $p = .003$. With regards to performance, results indicate that 12.7% of the variance in performance is accounted for jointly by grade level, age, sex, and auditory learning style of students. Auditory learning style preferences contribute 0.6% of the variance in performance, students' sex, age and grade level contribute 1.2%, 4.5% and 6.4% respectively. The male students' performance was better than that of the females, the JHS3 students' performance was better than that of the JHS2 but there was no significant difference between the performance of the age categories.

DISCUSSION

Learning Style Preferences of Students

JHS students were found to be more auditory in their learning style preferences than visual or kinesthetic. The dominant preference was auditory, 772(65%), kinesthetic 302(25%) and visual 114(10%). Comparing findings to the work of Brown & Cooper (1976), students of the Manatee Community College in Bradenton, Florida, (USA) were found to be 65% visual, 22% kinesthetic and 13% auditory. Apart from the kinesthetics who were comparatively near to each other, the auditory and visuals were directly opposite: the Ghanaian students were 65% auditory while the students in Florida were 65% visual. In high school grades 7^{th}, 8^{th}, and 9^{th}, in Cordoba, Sucre, Atlantico and Bolivar, Colombia, kinesthetic style was the most prevalent followed by tactile, auditory and then visual style (Juris, Ramos & Guadalupe, 2009). However, Aguirre, Cancino and Neira cited by Juris, et. al (2009) found that the auditory learning style was the most representative in a group from the National University in Bolgota. In East Asia, Korean, Chinese and Japanese students were all found to be visual learners, with Korean students ranking the strongest (Reid, 1987).

Considering the Ghanaian situation, the JHS students might thus be auditory learners because of their environmental upbringing. Most traditional Ghanaian homes expect children to exercise ‘obedience to authority’. Children are told: “listen to what I am saying” and if the child shows attention by looking directly into the face of the person, the child is rebuked “why are you looking at me like that”. It is a sign of disrespect if a child looks directly into the face of the one speaking to him or her. The child must “hear” not “see”. This practice has made children grow into adults who do not look directly in the face of persons speaking to them. At home children do not have much opportunity to ask the “why” “how” and “where” of things. They have little or no opportunity to educational materials to build upon their visual and kinesthetic experiences. Such practices of the home on behaviour, thinking and practice are likely influences on students being mostly “listeners” than “visualisers” or “doers”. This view is supported by the assertion that a learner’s style is a response to stimuli in the environment and with the types of tasks and problems the learner faces therein (Kolb, 1994, Sadler-Smith, Allison & Hayes, 2000).

Multimodal learning styles of JHS students

All the students (100%) had multimodal learning styles. Gilbert and Swanier (2008) assert that learning preferences facilitate the way individuals learn when the environment provides a variety of learning styles. The JHS students might be facing challenges while doing well the auditory way but perhaps not “stimulated” adequately to learn in other ways. Stevenson and Dunn (2001) suggest that many students can master easy information in the "wrong" learning preference for them, but they can learn more efficiently and rapidly when they use their own learning preference. Students would normally prefer to learn in a variety of ways, with each style of learning having its own unique strengths and weaknesses (Cook, 2000). Such multifariousness in learning styles suggests that it is important for teachers to consider this diversity in order to more fully harness each student’s learning potential (Kaplan & Kies, 1995; Wallace, 1995). If JHS students are not performing it also might be because of excessive auditory environment provided by schools and home. However, it is likely that they might perform better if they are exposed more to other learning styles preferences.

Sex on Auditory and Visual Preferences of Students

The study found that female students in the study were more auditory in their learning style preferences than their male counterparts while the male students were more visual than the females. These findings support views that as a group, females are more auditory than males and males are more visual and remain more kinesthetic than females (Dunn & Dunn, 1992, 1993; Dunn, Dunn, & Perrin, 1994). Brown (2007) reporting on the work of Diane Connell, a professor of New Hampshire's Rivier College said that “girls' left brain (responsible for speech discrimination) tends to develop more quickly than boys' left brain”. They (girls) are able to hear better. Boys' right brains - responsible for spatial and visual motor skills-develop faster than girls', so they do better in mathematics and prefer hands-on activities. In a similar report by Sax (2005), girls are shown to be born with a sense of hearing significantly more sensitive than boys, particularly at the higher frequencies most important for speech discrimination. Those differences grow larger as kids get older. Scientists have found that the girl can hear sounds much softer than the faintest sounds audible to the boy (Sax, 2005). These findings explain the higher auditory preferences of girls over boys and boys’ visual preferences over girls.

Learning styles, as indicated in the introductory chapter of this paper, might not be panacea for poor performance and neither could any one-to-one variable such as the home, the school nor the teacher be. What matters, however is the teacher’s ability in using the knowledge of these seemingly insignificant variables to enhance the adjustment of the learner to the learning situation. Students themselves need the awareness of their styles to encourage them take more responsibility for their learning (Felder & Brent, 2005).

Learning Styles and Personal Characteristics of Students and Performance

Findings show that learning styles and selected students’ characteristics, namely, age, sex, grade level, collectively contributed 12.7% to the variance in performance. The variance contributed by each of these significant variables (auditory 0.6%, sex, 1.2%, age 4.5% and grade level 6.4%) suggest that performance is not necessarily determined by any one-to-one variable. From among the three learning styles, only auditory preferences significantly contributed (0.6%) to the variance in performance which possibly was influenced by cultural practices and teachers' style (though not investigated).

With regard to better performance of boys over girls in science, stereotypes associating science with males than females across nations could have significant influences on variances in performance (University of Virginia, 2009). Males perform better than females in mathematics and science and the gap widens (and becomes statistically significant) by age thirteen and persists through secondary schooling (Dee, 2007). The magnitude of the gender gap in science achievement remains similar from fourth to twelfth grade (University of Virginia, 2009). Since this study has also indicated better performance of boys over girls it should be a matter of concern for science teachers. Teachers as the most causal factor in defining the quality of education in schools could design teaching sequences that could make learning of science meaningful for girls in order to bridge the widening gender gap.

Conclusion

Learning styles, specifically auditory, explained only (0.6%) of the variance in performance. However small the variance found in this study, it counts as it jointly with age, sex and grade level contributed to a greater variance of 12.7% in performance. Learning from learning styles could therefore be a variable of improving performance of the Ghanaian child in school science. It would require teachers to initiate processes that expose students to active participation in activities (doing) and provide equal or more opportunities also to "seeing" than "hearing."

ABSTRACT

Although liquid crystals can be found in several everyday devices, people know little or even nothing about them. In this contribution we present a teaching unit on these novel materials. Since the topic is very interesting, the unit can also be used to increase public motivation in science. The aims of the unit are: to teach students what liquid crystals are, to introduce students an additional phase and to show special optical properties on which liquid crystal display (LCD) technology is built. The teaching unit was tested among the first year undergraduate students of physics education. We present the results of the pilot evaluation of the knowledge gained by the unit.

Keywords: *liquid crystals, teaching unit, pedagogical survey*

INTRODUCTION

The development of modern science and technology brought liquid crystals (LCs) into everyday life. Many people are aware that liquid crystals are present in displays, phones, laptops… But they rarely know that liquid crystals also exist in natural systems such as biological membranes, cell membranes, DNA, silk and even in some skeletons of bugs… (Vilfan *et al.*, 2002; Brown *et al.*, 1983; Wright 1973). Technologically they are used in systems where fast response is needed. Despite the fact that LCs are quite common, youngsters have very limited knowledge about them. This was shown by the study on conceptions about the liquid crystals performed on the secondary school pupils' (Pavlin *et al.*, 2010). Although we were aware of the minute knowledge about liquid crystals in a general population, the results of the study additionally inspired us to design a teaching unit on these complex materials. The unit presented in this paper was prepared for the first year undergraduate students, who enrolled to the study program of physics education. This study program is designed for future teachers of Physics in the elementary (age 13 - 14) and secondary schools, except gymnasiums (age 15 - 18). In preparing the unit we took into account that the students have the unit in the first semester of the first year study at the university. So their knowledge of Physics is very limited since some of the students come from the secondary schools where they had no Physics course. Because of that the unit focuses on gaining qualitative understanding of the basic properties of the liquid crystalline phase.

THEORETICAL BACKGROUND

The teaching unit is composed from a lecture in duration of 90 minutes and a practical laboratory work of the same duration. The lecture explains basics about the liquid crystals as materials having a peculiar phase between the commonly known isotropic liquid and crystalline state. Then the lecture introduces the optical properties of liquid crystals and the technology of LC displays.

The laboratory work starts by students observing the three phases of liquid crystals. They measure two transition temperatures: the phase transition temperature between the crystalline and the liquid crystalline phase and the phase transition temperature between the liquid crystalline and the isotropic liquid phase. Liquid crystals are closed in a glass tube and they are in the crystalline phase at the beginning of the experiment. Students put the tube into the water bath and heat the water. They measure the temperature of the water which is assumed to be the approximate temperature of the liquid crystals in the tube. They first observe the transition between the crystalline and the liquid crystalline phase and measure the transition temperature. After a while, the transition between the liquid crystalline phase and the liquid phase can be observed and they measure this transition temperature as well. They observe and write down the differences of the appearance of the material in all three temperature regions (Figure 1, 2).

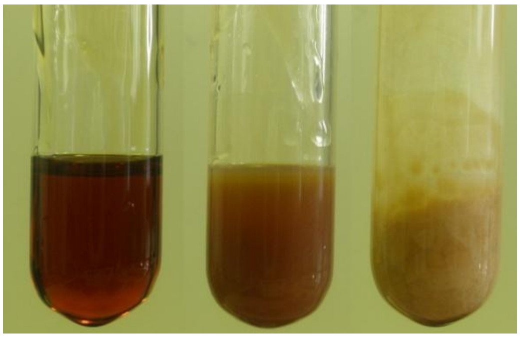

Figure 1: Liquid (left), liquid crystalline (middle) and solid (right) phase of MBBA.

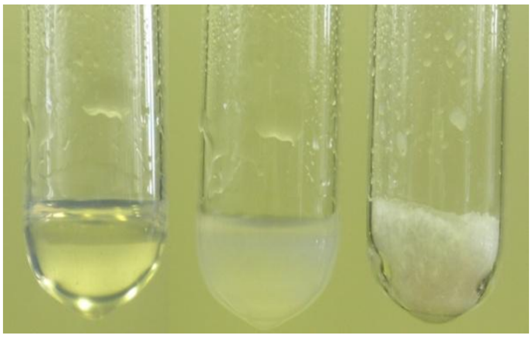

Figure 2: Liquid (left), liquid crystalline (middle) and solid (right) phase of cholesteryl benzoate.

Our students use two different liquid crystalline materials: MBBA (Figure 3) and cholesteryl benzoate (Figure 4). While students work in the laboratory, especially with liquid crystals mentioned above, they have to take into account safety precautions: they must wear safety goggles, lab coat and gloves. The first liquid crystal they handle with is cholesteryl benzoate which was the first material in which liquid crystal properties were discovered. In the late 1880s Friedrich Reinitzer, an Austrian botanist, while studying the chemicals in plants, heated cholesteryl benzoate. At 145 °C the material melted, yielding a cloudy fluid, which changed to the originally expected clear liquid at 178.5 °C. In 1888, the German physicist Otto Lehmann concluded the cloudy fluid presents a new phase of matter, and coined the term liquid crystal (Verbit, 1972). MBBA (n-4'-MethoxyBenzylidene-n-ButylAnilin) is one of the most prominent examples of nematic liquid crystals. The phase transition temperatures for MBBA from the crystalline to the LC phase occur at 24°C and the phase transition to the isotropic liquid is at 41°C (Liberko, 2000). Students notice the typical difference between the isotropic liquid and the LC phase: the first one is clear whilst the LC phase is opaque. This triggers further thinking on the reason for such a difference in optical appearance.

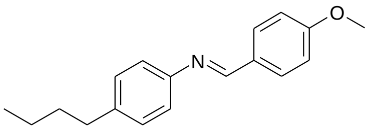

Figure 3: The skeletal formula of MBBA.

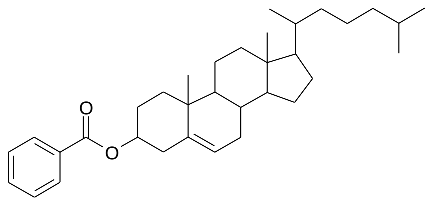

Figure 4: The skeletal formula of cholesteryl benzoate.

In the next experiment students use MBBA to make two prototype LC cells having parallel glass plates, the first cell with non-ordered liquid crystal molecules and the second with ordered molecules. The cell is made of a microscope slide, cover glass and a plastic foil. For the fabrication of the first cell students take the microscope slide and carefully set 2 layers of foil approximately 1.5 cm apart on both sides of the slide (Figure 5). They put a drop of liquid crystals on the slide, between the foil and place the cover glass on it (Figure 5, 6). For the second cell, a special kind of velvet is also needed to rub it against the slide. The fabrication procedure of this cell is similar to the procedure used by the first cell. Before putting the drop of liquid crystals on the slide, the slide is rubbed by the velvet in one direction (Figure 7). The micro notches are made on the glass. LC molecules at the surface align along these micro notches. This promotes the alignment of molecules everywhere in the thin LC layer between the microscope slide and the cover glass.

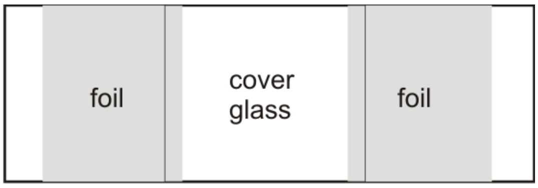

Figure 5: A sketch of a planar cell with parallel glass plates.

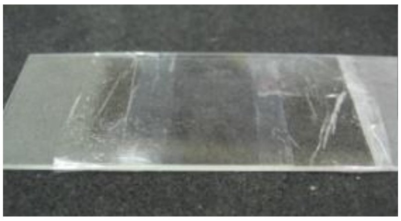

Figure 6: Planar cell

Figure 7: Rubbing the cover microscope glass by velvet in a certain direction

When the cells are prepared, students observe both of them between crossed polarisers under the school microscope (magnification: 300) and they describe the differences between these two cells (Figure 8, 9). The black line seen on the figures is a pointer of the microscope.

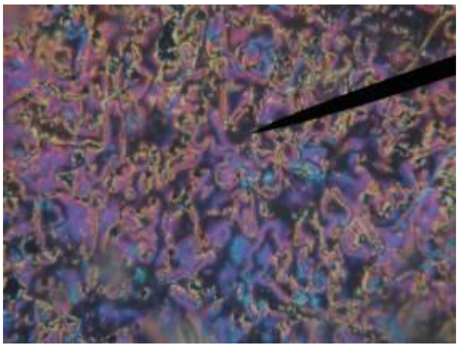

Figure 8: MBBA in a planar cell between crossed polarisers and observed under a microscope.

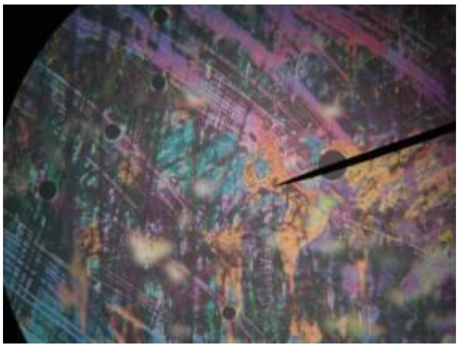

Figure 9: MBBA in a planar cell between crossed polarisers and observed under a microscope.

If one of the polarisers is turned for 90°, the colours switch to complementary colours (Figure 10).

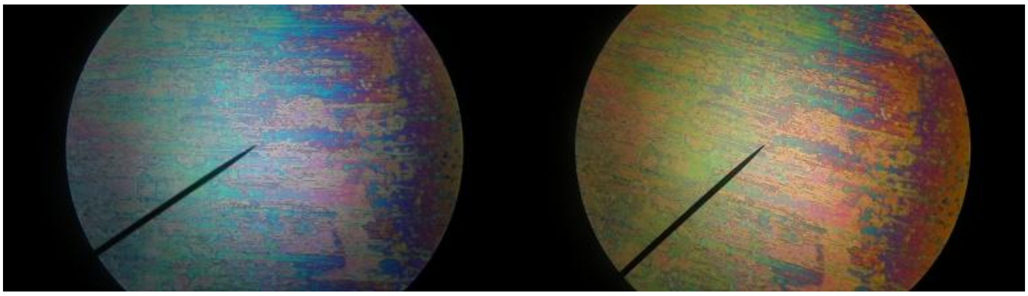

Figure 10: MBBA in a planar cell with notches, observed under a microscope when polarisers are crossed (left) and parallel (right).

It is also interesting for students to observe the liquid crystal cell under the microscope during heating the cell with a hair dryer. They can observe optical differences between the liquid crystalline phase and the liquid phase. The liquid crystalline phase is optically anisotropic and optically anisotropic materials have the capability to rotate the polarization of light. Therefore some light is transmitted when the cell is put between the crossed polarisers. When the cell is heated by a hair dryer the phase transition to the isotropic liquid occurs and one can observe disappearance of the colours. The cell observed under the microscope turns completely black.

The next step is to fabricate a wedge cell which can be used for visualization of the double refraction and the observation of mutually perpendicular polarization of the two beams. We use a wedge cell in order to obtain divergent ordinary and extraordinary beams, which are then observed on the remote screen. Students begin by carefully putting 6 layers of plastic foil on the microscope slide. Then they rub the slide with velvet in one direction. They put a drop of liquid crystal on the rubbed slide and place the cover glass on it (Figure 11). Then they shine through the cell with a laser beam and they can observe double refraction on the screen (Figure 12, 13). The following questions are posed to the students: i) Are these two beams polarized? ii) If they are polarized, what is the direction of polarization in each beam? iii) What happens to the beams if the cell is heated by the hair dryer (Figure 14)?

Students use the polarizing foil to answer the questions on polarization. They find out that the two beams (Figure 13) are polarized, polarization in one beam being perpendicular to the polarization in the other beam. When they heat the cell, one of the beams disappears. The beam which is specific for the liquid crystalline phase is called the extraordinary beam, while the beam that remains also in the isotropic phase is called the ordinary beam.

In this experiment as well as in the previous two, students used the liquid crystal sample that was produced in the school laboratory. The synthesis of the liquid crystal is another topic for another teaching unit so we shall not address it in this paper.

Figure 12: The experiment with a laser beam and a wedge cell.

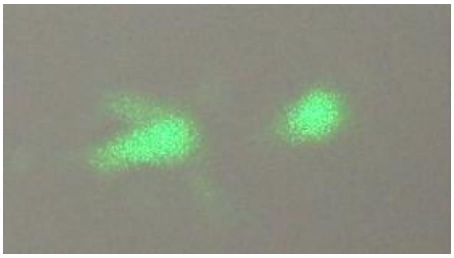

Figure 13: Double refraction in the LC phase, observed on the remote screen. Left: extraordinary beam; right: ordinary beam.

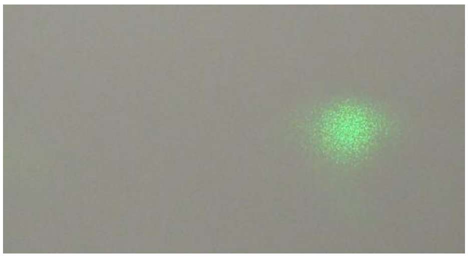

Figure 14: After heating the cell to the isotropic phase only one beam is observed.

METHODS AND RESULTS

In this pilot study we expected to obtain the answers to the following research questions:
- *How, and to what extent, does the designed unit bring knowledge about liquid crystals and their basic properties?*
- *How, and to what extent, do students gain knowledge about liquid crystals by means of the designed unit?*

The research questions are answered by means of a design research strategy. The design experiments were developed as a way of carrying out formative research, in order to test and refine educational designs based on theoretical principles as derived from the prior research. This approach of progressive refinement in design involves testing of the first version of a design in a real life to see how it works. Subsequently, the design is constantly revised based on experience, until all the 'bugs' in it are solved (Collins et al., 2004).

An objective of the design research is to make it possible to discuss and improve the effectiveness of teaching-learning strategies (Lijnse, 1995). The first design of a teaching-learning sequence or unit is based on theoretical aspects, experiences of the research group and the notions of the researcher. Once it has been designed, the development of a unit is a cyclic process of designing, testing in a real-life situation, and analysis of the collected data. The outcomes of one cycle form a basis for the second cycle. Thus the unit develops during research (Lijnse, 1995).

The analysis of the unit was done by chronological evaluation of the data obtained from testing. The testing of the unit took place in a class of 25 physics students and the first cycle of the testing of the unit was in December 2009. The testing took place in a classroom in which students could easily work in pairs. Students worked on the unit for about 95% of the estimated time. The teacher did not interfere with them during their discussions: this only took place when teacher – student interactions were planned.

The data collection took place by the classroom observations during the lectures and laboratory work, especially at the milestones with the respect to the activities of the unit, by a questionnaire filled out before the teaching took place (pre-tests), and by collecting worksheets with the students' answers (post-tests). The results of the pre test can be seen in the contribution of Pavlin *et a*l. (2010). The post test was a part of a written exam to make the students highly motivated for answering. The post test questionnaire included also some questions from the pre test, which made the evaluation more elaborated. An observer was helping with the experiments and detected the comments and discussions in the classroom. Data collection included the pre and post tests of all students and the classroom observations (field notes). The data analysis was mostly qualitative.

During the laboratory work we noticed that students were amazed over the colours they were able to observe in the LC cell under the microscope. The colours were directly connected to screens and LCD televisions. Beside colours the most interesting part was the wedge cell that caused the laser beam to split into two beams. Some students expressed the interest in the temperature dependence of the optical properties of liquid crystals as well. All comments show that students were enthusiastic about the unit and that they have never experienced a personal touch with the liquid crystals before.

Pre-tests included 17 questions of different types (Pavlin *et al*., 2010). On pre-test students on average achieved 24%. Most of the students who had heard about liquid crystals related them to displays. The pre-tests showed that students' knowledge about liquid crystals was very limited.

During the laboratory work students received the instructions for experiments on the worksheets. They followed the instructions and answered all the questions on the worksheets, more or less successfully, which was proven by the results of the analysis of the worksheets. The worksheets were scored and students on average achieved 83%. The results were quite stimulating for us. At the end of the semester students wrote the exam that included 3 questions related to liquid crystals and served as post-test. The results revealed that all of the students were able to list at least 3 products where the liquid crystals are integrated in (100%). The question connected to double refraction of liquid crystals was noticed to be well understood. The teaching unit helped students to visualize and understand the phenomenon of double refractivity as well as the role of liquid crystals (on average students achieved 70%). The last question revealed the lack of knowledge on the properties of liquid crystals that makes them special and distinguishable from other substances. Most of the students were not able to recognize the properties that are essential for the use in technology. Only 30 % answered correctly. Nevertheless if we consider the average score of the post test we can conclude that the improvement in knowledge is significant: from 24% at the pre test, to approximately 70 % at the post test.

CONCLUSION

By means of the activities in the unit on liquid crystals students were guided to gain knowledge about liquid crystals. To answer the first research question: "*How, and to what extent, does the designed unit bring knowledge about liquid crystals and their basic properties?"*, we analyzed the data which were acquired from the testing of the design unit. If we start with goals of the teaching unit, we can easily find out that the unit enables assimilation of knowledge of a new topic in physics – liquid crystals. The teaching unit presents the students a new, liquid crystalline, phase and it gives a qualitative explanation of colours and double refraction. To answer the second research question: *How, and to what* *extent, do students gain knowledge about liquid crystals by means of the designed unit?*, we take into account the data from the pre- and post-tests and detect on average a significant progress in the basic knowledge of liquid crystals, regarding their optical properties and application.

Our results show that further work on this interdisciplinary topic, which should be carefully included into the physics and chemistry curricula, is worth the effort.

The conclusions are limited, because only 25 students were involved into this pilot study. However, the result shows that it is worthwhile to follow up this design study with larger groups of students at different study programs.

Europe faces the problem of low motivation for natural science studies. Introduction of contemporary research and technological problems into science teaching makes the context of learning more motivating especially when students are actively involved. Inclusion of topics on liquid crystals into syllabus makes studying of physics more meaningful as it brings everyday life into the classroom.

ACKNOWLEDGEMENTS

The team would like to acknowledge the interest and the willingness of cooperation of the students in the first year studies of physics education in the academic year 2009/10. The work reported here was partly financed by the Ministry of Higher Education, grant No. J5-0365-0588.

WHY CHOOSE A TECHNICAL CAREER?

Håkan Ahlbom

University of Gävle

hanahm@hig.se

Edvard Nordlander

University of Gävle

enr@hig.se

ABSTRACT

Technology is a neglected mandatory subject in the Swedish compulsory school. The subject is supposed to inspire young people to consider a technical career, due to an increasing need for engineers and a declining recruitment to engineering education.

An investigation of influential factors for choosing a technical career is presented. The factors are well-known, but the relative impact of the factors is investigated using questionnaires and semi-structured interviews with engineering students. Special focus is put on the effect of previous technical schooling. The most important factors for choosing technical education are personal technical interest, future salary expectations, and personal qualities.

Keywords: *Impact factors, technical education, career choice, semi-structured interview.*

INTRODUCTION

Technology is a mandatory subject in the Swedish compulsory school since almost 30 years, and for the last 15 years it is a separate subject with a syllabus of its own.

The Swedish Education Act states that all children shall have equal access to education in the national school system (SFS No: 1985:1100). The municipalities are responsible for providing compulsory schooling to all children. The Swedish government is clearly stating a goal for the Technology subject to ensure pupils developing an interest in technology, as well as ability and judgment when handling technical issues (Skolverket 2000). However, the Technology subject seems to be lost in practice. This is shown by *e.g.* the governmentally commissioned Swedish Technology Delegation (Teknikdelegationen 2009). As a result of this neglect, the Swedish school system is putting the interests of public demands and society aside. This will harm the Swedish society in the long run.

Does this mean that more pupils should be inspired through the Technology subject in compulsory school to consider a technical career by means of increasing the technical interest? In a previous version of the syllabus for the Technology subject given in the national curriculum, Lpo 94, it was stated that the education in Technology also should stimulate the technical interest for both girls and boys and to facilitate their future choice of study and career.

Hence it seems so, but for some reason this part of the syllabus was deleted in a later revision. Regardless the reason for that, there is an increasing need for engineers in Sweden due to declining recruitment of engineering students during the last decade. In this paper, the relative impact of influential factors given by engineering students to choose a technical career is presented.

METHOD

The hypothesis of the investigation is that an engineering student has got a driving force towards being an engineer. This driving force is not always clear to the student, but there are several influential factors, either promoting or opposing, in the process of being an engineer. Most of the factors are well-known, but in this investigation the relative impact of the factors are given. The method used in this investigation is based on questionnaires and semi-structured interviews with 3-year engineering students at a regional, medium-sized university in Sweden. The engineering programs represented in the study are electronics, computer, mechanics, industrial economics, geomatics, and construction. In the questionnaires the student could rank the importance factors (from a given list) for attending an engineering education. The factors given in the list were chosen from literature, with justification from interviews done.

There is a specific focus from the authors on the effect of previous technical schooling as a factor, especially the mandatory Technology subject in compulsory school.

RESULTS

School subjects seem to have different influence on the choice of education. This is due to the different kinds of engineering education represented in the study. For electronics, computer and mechanical engineering students, mathematics along with physics were important factors. For industrial economics and geomatics students, mathematics along with geography and social sciences seems more important for their choice. More than one third of the students thought that none of the subjects in compulsory school had influence of their choice, but more than half of the students thought that upper secondary education influenced their choice. Taking a technical program at upper secondary school seems to be an important factor for the choice of education, and many of the engineering students come from natural science or technical programs in upper secondary school. An interesting result is that very few students considered the Technology subject in compulsory school as an important factor for choosing engineering at the university.

The most important factor for choosing a technological education was a personal technical interest, followed by future salary expectations, personal qualities, and the status of expected position. The geographical location of the education was more important as a factor than the (status of the) university itself. Next in rank came personal influence from parents, relatives, friends and other persons. In the interviews there is often a specific person, working as an engineer or otherwise involved in the technical domain, who served as role model for the student. Teachers and student counselors do not seem to have a dominant impact on the choice. None of the students thought of gender as influential on the choice of education.

The most important personal qualities for the choice of technological education were logical capability, technological literacy, curiosity and mathematical interest. Only few thought that persistence or sociability were important in this respect, and none picked political interest or artistic capability.

CONCLUSIONS

The results from the questionnaire verify that the Technology subject in compulsory school is lost in practice. The subject had virtually no impact on their decision to choose engineering.

Almost all students claim that they only took the subject in the three last years, although the national curriculum prescribes the subject in all 9 years of compulsory school. Is it really so that they didn't get any education in technology in early years, or was it integrated into other subjects? No matter what, it is obvious that the subject is failing to promote higher technical education for the students. The most influential subjects in school are mathematics together with other subjects depending on the direction of engineering taken by the student.

The most important factor is the personal technical interest. One of the goals to aim for in the syllabus for the Technology subject is *"that the pupils develop their interest in technology" (Skolverket 2000)*. If students do not consider the Technology subject as an important factor for choosing a technical education but nevertheless find themselves technically interested, where does the technical interest come from? What factors are building a technical interest more efficiently than school? Furthermore, technical literacy was considered as an important personal quality for choosing a technical education. Technical literacy is also one of the reasons for having a Technology subject in compulsory school. But if the Technology subject has no impact on technical literacy, where did it come from?

It is interesting to notice that although only one out of four Swedish engineering students are female, none of the respondents regarded gender as influential on their personal choice of education. The result may be interpreted as a problem not situated on the personal level, but rather being of another dimension. In the interviews the students explain the situation as a matter of influence from early childhood, in the different way girls and boys are treated. One student indicated that if you give traditional dolls to girls and Transformers, *i.e.,* technically advanced fantasy dolls, to boys, children are indoctrinated that technological advanced toys and technology are for boys.

ABSTRACT

The paper is based on research regarding the comprehension and involvement of undergraduate students with the principles of sustainable development (SD). The students which have taken the survey were in the last years of their engineering studies at the University of Maribor, Slovenia. They answered via questionnaire to some basic inquiries about understanding sustainable development and following its principles. The study also includes students' point of view on professors' connecting the SD principles with the topic of their lectures, together with their opinion on the collaboration between university and other institutions (state and municipal authorities, enterprises, research institutes, etc).

Keywords: *Sustainable development, engineering education.*

INTRODUCTION

The complex and evolving concept of sustainable development is differently comprehended and accepted around the world. More than twenty years passed since the concept was introduced; but its principles are continuously developing, and new ones emerge from the needs and demands of today's society. But the needs of the present generation should be met without compromising the ability of future generations to meet their own needs (IUCN, 1980). After being accepted as the concept that should guide all actions for building a better future, many organizations tried to define the principles of sustainable development. The intention was to attract and employ stakeholders into actions that support, apply and develop these principles. Universities, through there triple role – research, education and innovation – should occupy a key position in promoting sustainable development by providing students with both knowledge and skill; knowledge on how to identify and analyze the problems facing today's society and to forecast future consequences; and skills in dealing with these situations today and in the future. While many nations around the world have recognized the importance of education to build capacity to achieve sustainability, only limited progress has been made with implementing it. This lack of progress stems from many resources. One of the reasons is that the need for change is not readily apparent. Lack of or inadequate national, regional and local policy to support education for sustainable development (ESD) has also impeded progress. But probably the major obstacle is the lack of resources such as funding and trained personnel.

METHODS

To analyze the familiarity of the future engineers from the University of Maribor with sustainable development and its principles a survey was conducted. The survey comprised 28 undergraduate students from Faculty of Chemistry and Chemical Engineering and Faculty of Electrical Engineering and Computer Science. The questionnaire seeks to find out whether future engineers already heard about sustainable development, if they are familiar with its principles and if they follow them in professional and domestic environment.

RESULTS

The survey showed that only 46% of students that answered the questionnaire have already heard of sustainable development. Out of these only 7% are familiar with its principles. The questionnaire included questions on how/if the professors involve sustainable development in their lectures/exercises. Almost 40% of students answered that there is no connection between the lectures and the principles of SD. 57% consider that SD is poorly integrated in the curriculum, while only 3% think that lectures and seminaries completely involve its principles. Based on the previous question, we were interested where did future engineers hear of SD. 23% heard during their studies at the University, while 77% through media, internet and other sources. Most of them (70%) got familiar with the topic a year or two ago. As going deeper into the problem, we see that there is no collaboration between faculties and students on discussing measures of sustainable development in their institution. On the other hand more than half (63%) of the enquired students are partially aware of the impact their faculty's activity has on the environment and natural resources. The proposed and applied measures by each faculty are very poorly introduced to students. Only 11% think they are familiar with these measures while 32% are partially familiar with the actions taken by their institution. Furthermore the survey showed that 93% of students are fully or partially aware of the impact of their domestic activities on environment; 89% of them are fully or partially aware of measures that reduce this impact; and 82% apply sustainable measures in their domestic activities. Two thirds of the enquired students believe they do not have enough possibilities to learn more about SD. On the other hand 30% are interested in obtaining more information and they also propose the means of obtaining this information; they propose seminars (44%), additional lectures (22%) and conferences and workshops (34%). Based on this survey we can conclude that knowledge on SD is very limited with future engineers graduating from our University. The results show that professors and assistants do not introduce the principles and measures of SD properly or even avoid introducing them in their lectures and seminaries. This fact is concerning as work of these future engineers will have a huge impact on environment and exploitation of natural resources.

CONCLUSION

Sustainable development is hard to define and implement, and also difficult to teach. Even more challenging is the task of totally reorienting an entire education system to achieve ESD. Universities play an essential role in implementing these changes. The concept of SD and its segments – environmental, economical and social – may be easier understood at this level, and thus these changes may be easier put into practice. The main conclusion of the survey presented in this work is that most of the participants do not know what SD is and what its principles are about, although they follow some of its principles in their domestic activities. This suggests that SD and its principles are poorly introduced and explained in the curricula, while students are not involved in activities which may encourage them to employ these principles in their professional and personal life. Changes should be made at all levels of education, and lifelong learning should be acknowledged as an essential tool in professional and personal development.

ABSTRACT

Several institutions, the municipality being at the forefront, conduct studies and offer suggestions concerning the environment conditions in Ankara. "Planting on Martyrs' Lands" and "Tree Surgery and Landscaping the Capital" were conducted and then "Integrated Biological Control" program was developed. Results of this study indicate that students and teachers have general information about the environment however, they are not aware of their living environmental problems and ongoing studies. Environmental works, which Ankara Metropolitan Municipality pursues, are tried to publicize by media but those announcements either do not reach the education sector or are not enough taken into account.

Key words: *Environmental awareness, Environmental problems, Environment-related projects, secondary school.*

INTRODUCTION

Environmental problems faced in Ankara have been increasing with its growing population. Ankara is faced with some environmental problems such as energy efficiency, waste destruction, waste treatment and recycling, drinking water purification, preventing the spread of contagious and infectious diseases preserve natural habitat in Ankara, air pollution, noise pollution, unplanned urbanization.

Environmental education is very important to monitor environmental problems closely, to create a healthy environment, to have people who are aware of individual rights and responsibilities and ensure the consciousness of environmental problems and contribute in solving them. In other words, the purpose of education for environment is to have a sustainable development and to show people ways to living in peace with nature (İleri, 1998).

The individuals who are responsible for the occurrence of environmental problems should be conscious of eliminating these problems. This will be possible only with an active environmental education. In the environmental education, the target population is all individuals and the goal is to develop their sensitiveness, positive attitudes and behaviors towards environment (Özmen, Çetinkaya and Nehir, 2005). Therefore, in this study, answers were sought to the following questions:

1- How informed are the secondary level teachers and students living in Ankara about the environmental problems in Ankara?

2- How informed are the secondary level teachers and students living in Ankara about the solutions recommended for the environmental problems in Ankara?
3- Do the secondary level teachers living in Ankara give importance to environmental education?
4- How far might the solutions recommended for the environmental problems in Ankara be applied to the field of education?

The awareness of teachers being the intellectual part of the society and students who will be intellectual people of the future about environmental problems of the city they lived are curious. The impotency of environmental education can be revealed by determining the level of knowledge and the applicability of this knowledge of secondary education teachers and students lived in Ankara.

As mentioned earlier, the environmental education of future generations will increase their environmental awareness. This research is important to understand how far they are ready for the potential future environmental problems and to know their environmental conscious level as a future parents and teachers.

METHODS

In this study the general screening model was used. Data were obtained through the questionnaire, which was developed by the researchers, to determine how the secondary level teachers and students in Ankara are informed about the environmental problems and their solutions, and their relevant actions.

In the process of creating a survey, Ankara's environmental problems and the latest information about the Municipality’s solutions for these problems were gathered by following an official web site of Ankara Metropolitan Municipality and its published periodicals. At the same time at Ankara's natural riches were investigated (Ankara Metropolitan Municipality, 2008; Atatürk Forest Farm, 2009; The Ministry of Environment & Forest, 2009). To create a survey the statements related to some topics were prepared. After the preparation of the survey, its reliability and validity studies were conducted. The survey was conducted on The Gazi University, Gazi Faculty of Education, Science Department the 3rd grade students in order to determine the reliability of the survey. The reliability of the test was found as $\mu = 0.76$. Then the survey was conducted among 9^{th}, 10^{th}, 11^{th} and 12^{th} class students and the teachers in 4 different high schools in Yenimahalle, the district of Ankara. 118 high school students and 30 teachers participated in this study.

RESULTS

1. Environmental Awareness

Survey results were revealed that students are worry about the environment and its future. The rate of warning people who pollute the environment was 61%, which is pleasing. This indicates that the environmental awareness of students has already developed. 75.4 percent of students are worrying about whether their children will live in a clean environment in the future. The rate of students’ awareness about environmental studies was low. This indicates that environmental studies cannot be presented enough or they are not introduced sufficiently at media and technology tools which students use frequently.
43 percent of teachers think that environmental studies are sufficiently presented by media but 33 percent of them do not so. This shows that ongoing environmental studies are not sufficiently announced. Also, the teachers are not aware of environment-related works.

2. Ankara's Environmental Problems and Solutions

Survey results showed that teachers and students did not have enough information of Ankara's environmental problems and ongoing studies to resolve those issues. Teachers and students were not aware of the fights against houseflies, mosquitoes and head louse. In addition, they had information about plant cultivation to increase green areas, but they did not know that whether or not properly done.

3. Ankara Metropolitan Municipality's Studies Related to the Environment

73 percent of the students found that the efforts of Ankara Metropolitan Municipality on environmental works were sufficient. 53.3 percent of teachers found the same works as sufficient. The study results showed that teachers know much more than the students considering environmental works of Municipality.

4. Ankara's Natural Richness

The results of study showed that teachers and students participating to the study did not have enough information on Ankara's natural richness. Only 36.4% of the students and only 33% of teachers know that rabbits, foxes and hawks live their natural life in an area of 7600 decars belonging to the Atatürk Forest Farm in Ankara. Student responses to the statement "I know that organic products will be sold and villagers will have the natural village (rural) life in Muratlı, an ecologic village located at a distance of 58 km to Ankara" are following. 43.2 percent of them chosed "do not agree" and 51 percent said "undecided". Teacher responses to the same statement are that 38 percent said "do not agree" and 38 percent said "undecided". Results show that students and teachers are not aware of conducted organic life in the village of Muratlı.

CONCLUSIONS

Today, the rapidly increasing world population, rapid industrialization and unhealthy urbanization, nuclear experiments, pesticides, artificial fertilizers, chemicals have started increasingly polluting the environment, thus; the contaminated air, water and land have become harmful to all living creatures and finally each has turned out to be an environmental problem with which we face now. These problems might be overcome radically by educating students from primary schools to all level schools. Survey results indicate that students and teachers have common information about the environment, however they do not know enough their living environmental issues and ongoing works for the relief of environmental problems. The environmental works conducting by Ankara Metropolitan Municipality are tried to publicize by using the media, but those announcements do not reach the education sector, or are not enough taken into account.

THE ELEMENTARY SCIENCE TEACHERS' USE OF MEASUREMENT AND EVALUATION TECHNIQUES

Ela Ayşe Köksal
Niğde University
eakoksal@nigde.edu.tr

Hülya Yıldırım Ekinci
Niğde University
hulyaekinci@nigde.edu.tr

ABSTRACT

With the recent reform in Turkey, science curriculum has accepted more constructivist approach to measurement and evaluation and given importance to alternative evaluation techniques.

This study aims to explore the degree to which elementary science teachers use these techniques. A survey with 58 teachers in Nigde city, town and village showed that the teachers' use of the techniques formed seven dimensions: (1) Traditional and Close-Ended, (2) Conceptual, (3) Student-Centred, (4) Traditional and Open-ended, (5) Long-Termed and Authentic, (6) Dialogic and (7) New and Alternative. This study also aims to explore the usage level of these measurement and evaluation techniques and see if any or some of the dimensions are used more (or less) than the other techniques forming a specific dimension.

Keywords: *elementary science teachers, measurement and evaluation, curriculum.*

INTRODUCTION

Measurement and evaluation has an important place in education and teaching because it aims to assess the quality of education and make it more successful by eliminating the shortcomings. Additionally it is used to determine the degree to which the course objectives are met, what subjects are taught, and which student characteristics are affected by teaching.

In constructivist approach, assessment should not be done apart from the teaching/learning process. Rather it should be done continuously.

With the recent curriculum reform In Turkey, science curriculum has accepted more constructivist approach to measurement and evaluation. The new program has given importance to alternative techniques, such as performance evaluation, portfolio, concept map, structural communication, diagnostic tree, word association, project, drama, interview, written report, demonstration, poster and group-, peer- and self-evaluation.

It is reported that due to time limitations, material shortage, class population excessiveness, and teachers' unsuitability, the program has potential drawbacks.

This study aims to explore the degree to which elementary science teachers use these techniques. This study also aims to explore the usage level of these measurement and evaluation techniques and see if any or some of the dimensions are used more (or less) than the other techniques forming a specific dimension.

METHODOLOGY

The population of this study was all elementary science teachers attending village, town, and city elementary schools in Nigde. The sample on the other hand was 58 teachers who completed a questionnaire during the seminar activities in their schools on June 2009. The questionnaire was intended to evaluate the elementary teachers' degree to use measurement and evaluation techniques in their science lessons. The science and technology curricula for elementary 4-5 and 6-8 grades were used by the researchers to construct the item statements. The questionnaire had 22 items and five-point-Likert scale.

The data from the teachers were analyzed for validity (KMO and Bartlett's Test, and factor analysis), and reliability (in terms of internal consistency) issues and factor analysis was done. The conclusions were drawn by considering the mean scores of the teachers' responses to the each item.

RESULTS

The Cronbach Alpha value of the questionnaire data was found to be .82, which states that the instrument is reliable enough to use in determining teachers' in-class assessment applications. Moreover corrected item-total correlation values were above .20, which states that all items are contributing to the whole measure as well.

The investigation of the data with the KMO Test gave enough result (.63) and Bartlett's Test was significant to conclude that the data were ready for factor analysis. The factor analysis was conducted with principal component analysis with varimax rotation. The result of the factor analysis showed that the teachers' use of the techniques formed seven dimensions, which contributed to the 75% of the variance on the scale scores: (1) Traditional and Close-Ended, (2) Conceptual, (3) Student-Centred, (4) Traditional and Open-ended, (5) Long-Termed and Authentic, (6) Dialogic and (7) New and Alternative.

When the mean scores representing the teachers' usage level of measurement and evaluation techniques were considered, it was found that the teachers use long termed and authentic ones nearly always (the means are 4.44 for performance evaluation and 4.08 for project).

The teachers use dialogic techniques usually in their science classes (the means are 3.81 for concept map and 4.06 for question-answer test),

The teachers use traditional close-ended techniques usually in their science classes (the means are 4.13 for multiple-choice test, 3.96 for fill in the blank test, 3.92 for matching test and 3.79 for true-false test).

Though the mean score is little bit high for short essay test, the teachers are likely to use traditional open-ended techniques sometimes in the science and technology lesson (the means are 3.42 for short essay, 2.98 for long essay and 2.90 for interview types).

The teachers use conceptual techniques sometimes at the class (the means are 3.19 for demonstration, 3.13 for word association, 2.98 for diagnostic tree, 2.88 for drama and 2.81 for structural communication).

Among the new and alternative techniques, the teachers are likely to use poster (3.83) and portfolio (3.56) usually, but use written report (2.81) sometimes.

Lastly, the teachers seem to use student-centred techniques sometimes (from 2.75 to 2.81).

CONCLUSION

This study revealed that the teachers though in some of the dimensions might use alternative techniques less; they could implement the techniques at class. Alternative techniques as the curriculum suggests are reliable, performance based, valid, constructivist and applicable. And they can help teachers to understand what, why and how to teach as well as to measure meaningful learning and deal with students' misconceptions and learning difficulties.

The teachers' responses to the questionnaire were indicated a clear difference between traditional and alternative techniques stated by the curriculum. For example multiple choice, fill in the blank, matching and true-false tests constructed a separate dimension. On the other hand, question-answer technique was loaded in the factor with concept map that is though to be alternative. From the dialogic teaching, teacher-student talk and feedback point of view and the personal experience (of the first author) it can be said that the aim of classroom assessment should be to guide students on their school learning.

IS TECHNOLOGY AN ATTRACTIVE SCHOOL SUBJECT? A PILOT STUDY OF THE SUBJECT IN THEORY AND PRACTICE.

Ylva Bjelksäter
University of Gävle
ylabjr@hig.se

Edvard Nordlander
University of Gävle
enr@hig.se

ABSTRACT

How does a teacher convey technological understanding through interactions with learners?

A case study is performed using a stimulated-recall methodology with one teacher in a limited Technology learning module in grade 8. Based on the official syllabus and local interpretations, what in fact occurs in the meeting with pupils is discussed regarding how technology is portrayed by the teacher.

An important result is what messages about technology the teacher is expecting the pupils to understand from each lesson. In order to get appropriate feedback, selected pupils are interviewed about their impressions of the lesson.

Keywords: *stimulated recall, Swedish compulsory school, technology subject, syllabus fulfillment, effect.*

INTRODUCTION

Technology was introduced as a mandatory subject in Swedish compulsory school in 1980 and got its own syllabus when the current national curriculum was introduced in 1994. Each school can decide when and how the pupils get technology education, but every pupil is expected and entitled to reach the national goals (SFS No: 1985:1100), *i.e.*, learning outcomes set by the government.

In order to find out if and how pupils reach the national goals in Technology an investigation is performed about how the specific Technology syllabus is interpreted, in theory and practice. The findings of the project will contribute with answers about the state of the Technology education in the Swedish compulsory school system, and how the subject could be developed in the future. In this paper the first results are presented.

According to Alexandersson (1996), a teacher is continuously performing spontaneous acts without much of reflection, commonly referring to habits "we usually do it like this" or a feeling of justification "it feels right to do it this way". Many of our actions are guided by habits and/or emotions, and the teaching situation is seldom an exception.

METHOD

Research question: How does the teacher convey/develop technological understanding through their interactions with learners?

The interpretation of the syllabus is studied through observations. This pilot study is performed as a case study with a teacher in a limited module of the Technology subject in grade 8 (14-15 year old pupils). The teacher is chosen by the school management as favorable example of good practice. The method is based on a stimulated-recall interview methodology (Walmsley 2008, Alexandersson 1994, Calderhead 1981). In the stimulated-recall interviews, video filming is a substantial part of the method. Thus, a miniaturized video camera is hooked on the teacher recording the actions in class of the pupils along with the dialogue between teacher and pupil. In the interview part, the video clips are used to help the teacher to recall the interaction at various moments and explicate his interactive thinking.as regards situation, strategy, thinking, reactions, learning impact, etc.

The results of the stimulated-recall interviews will be put upfront to the syllabus and other guiding official or semi-official documents. Interviews are conducted with the pupils about how they perceive the technology education in order to get some receiver feed-back of the education

The case study

The assignment is to construct a model of a house, either from a template of a log cabin, or an existing house in their neighborhood. Available for the construction are popsicle sticks and flower pegs, hinges, glue, and various tools. There is no specific laboratory for the technology education, so a regular classroom is used where the material and tools are presented on a trolley, and the pupil-made models are stored on shelves in the classroom between lessons.

The groups are composed by the pupils themselves, and there are 6 groups with 2-5 pupils in each: The learning module is arranged with only one 45-minute lesson per week for almost a full semester.

The teacher (male, 50 years old) has been teaching for 20 years and is considered quite experienced. His teaching subjects are Mathematics and Science (where Technology normally is included). He has taken in-service training courses in Technology. He is has a calm personality and rarely gets annoyed. He is appreciated both by pupils and colleagues.

The assessment of this teaching module is done by the teacher based on four criteria: quality, details, aesthetics, and cooperation. The governmentally set learning outcome by the end of the 9th year for this module of Technology education is: To be able to build a technical construction using own sketches, drawings or similar support, and to describe how the construction is built up and operates.

RESULTS

When the pilot study started the pupils had already begun with the constructions. At the first visit they were sawing, rasping, and putting the flower pegs together with clue. At the second and third visit they were still occupied with this.

The pupils thought it was boring because it took so long time to saw and rasp all the popsicle sticks and flower pegs. They made little progress, and some of them did not believe that they would be ready on time. The teacher had not yet decided when the project should be finished. However, at the fourth visit one group had started with the roofing.

Not all pupils were taking responsibility for the work. A couple of boys did not seem to be doing much, and most of the time they just sat and watched the others working.

When asked, the pupils said they enjoyed Technology although it was sometimes boring. The reason for this opinion was the practical character of the subject and the lack of formal tests. However, they did not have the feeling of learning anything new. Furthermore, they were not sure what would be assessed by the teacher when grading the pupils' achievements in the Technology subject. Some of them, however, remembered something about cooperation as an important criterion.

CONCLUSIONS

The results give an impression of what in fact occurs in the meeting with the pupils, and how the meaning of Technology is portrayed and conveyed by the teacher to the pupils. For the specific module of learning typical knowledge and skills are involved.

In the interactions between teacher and pupils, the language used for communicating the learning issues is of major importance. So, an important result is to find out what messages about technology the teacher is expecting the pupils to understand from each lesson. The results show that assessment criteria are not clear to the pupils. Only the cooperation criterion was given by some pupils, but *e.g.* the aesthetics criterion was not understood.

An impression of boredom compensated by the lack of formal tests is giving the Technology subject a character different from other school subjects. This is most certainly neither the intention of the authorities nor the teacher.

A major intention of the teacher with the assignment is to evaluate how the pupils cooperate and which different solutions they use to solve the task. Due to the divergence in interest emerging through the low pace during lessons, this assessment will be very difficult. It is not the subject *per se* which is diverging the pupils' interests. It is the circumstances around it, *e.g.*, the non-technical environment, lack of material, the formation of groups as regards size and membership, low speed of progress, organization of lessons.

EVALUATING THE IMPACT OF ENVIRONMENTAL EDUCATION: COMPARING THE NEP AND THE 2-MEV AS OUTCOME MEASURES

Jelle Boeve-de Pauw
University of Antwerp
jelle.boevedepauw@ua.ac.be

Peter Van Petegem
University of Antwerp
peter.vanpetegem@ua.ac.be

ABSTRACT

The environmental worldview came to researchers' attention in the mid-seventies and is now making its way into the evaluation of EE. The use of this non-cognitive, yet quantitative evaluation method is promising in the current era of accountability. In this paper, we compare the theoretical foundations of two contemporary measures for children's environmental worldview: the NEP and the 2-MEV. Both scales are used to tap children's environmental worldview (n=1287), and to assess the impact of a popular environmental education school (n=60) programme using multilevel analysis.

Keywords: *2-MEV, Children's NEP, Educational Evaluation, Environmental Worldview, Multilevel Analysis*

INTRODUCTION

Evaluation of environmental education initiatives is a very difficult and complex task, but one that is of outmost importance. The degradation of the natural environment is increasing exponentially. The way humanity is mistreating the earth and its natural riches in a single lifetime will impoverish our descendants for all time to come. Knowing this, it is clear that environmental education has to be effective. A concept that is making its way into the evaluation of environmental education is that of the environmental worldview, first described by Dunlap and Van Liere (1978). It consists of what social psychologists call a set of *primitive beliefs* that constitute the inner centre of a person's belief system on the truth about the physical and social reality. Instruments that try to capture this concept are abundant since numerous authors have developed their own instruments for their specific studies. As Leeming, Dwyer & Bracken (1995) point out, the availability of a carefully developed and psychometrically sound scale to measure children's global environmental attitudes (or environmental worldview) would be a valuable teaching and research tool. Such a scale would provide one common standard against which the effectiveness of various interventions could be judged and compared. These comparisons would greatly facilitate the systematic development of more effective interventions to promote pro-environmental attitudes (and behaviours). Recently two scales are receiving increased attention in this area of EE research: Manoli, Johnson & Dunlap's (2007) Children's New Ecological Paradigm (NEP) scale, and Bogner and Wiseman's (2006), Model of ecological Values (or 2-MEV). The children's NEP sees the environmental worldview of children as a one-dimensional trait with Ecocentrism and Anthropocentrism as extremes, whereas the 2-MEV is two-dimensional by design and structurises youth environmental values on the orthogonal factors Preservation and Utilisation. Furthermore, Johnson & Manoli (2008) show that the environmental worldview of children can be considered both as stable when students are not exposed to EE and as changeable when students are exposed to EE. Both the children's NEP and the 2-MEV have been used to illustrate difference between groups of students and the impact of EE. The current paper compares the theoretical foundations of both scales, and goes deeper on the assumptions of using worldview based scales for EE evaluation.

AIM AND METHODS OF THE STUDY

Both instruments (NEP, α=.70; 2-MEV: α(P)=.81, α(U)=.86) were used to measure the environmental worldview of Flemish children (n=1287, ages 11-13), and to assess the impact of a popular Flemish EE school programme. In total 60 school participated in the study, 30 of which were enrolled in the EE programme; the other paid no specific attention to EE. We furthermore collected data on the children's gender, socio-economic background (α=.68), environmental knowledge (α=.87), affections toward the environment (α=.95), environmental behaviour (α=.75) and behavioural intentions (α=.79). The data were analysed using a multilevel regression approach, allowing for differentiation between individual and school level effects. We furthermore built a structural equation model to test for both environmental worldview scales the theoretically assumed link to behaviour and the potentially mediating functions of environmental affection and knowledge.

RESULTS AND DISCUSSION

The multilevel analyses reveal that the EE programme has an effect on the students' environmental worldview (as measured by both scales). At the school level, students from schools that participate in the EE programme score .320 standard deviation higher on the NEP scale than non-EE schools, indicating that they have a more ecocentric way of looking at the world. If we look at the 2-MEV, we see a school effect of -.320 for the Utilisation factor (U) and no school effect for the Preservation factor (P). These results nuance the NEP effect in that they reveal the EE schools to temper their students' utilitarian views of the natural world but that they do not stimulate their preservative values. The next step in our analyses was to build a path model to test if behaviour change (the ultimate goal of EE) can be reached through schools affecting only the U factor. This model shows that, through the mediating effect of behavioural intentions, it are preservative values that affect behaviour (β=.52), whereas utilitarian values have no effect. Furthermore we integrated environmental affection and knowledge into the path model, the results of which show that students P views (and thus ultimately behaviour) can be reached through affection (β=.55), and their U views through knowledge (β=-.41). We then also compared affection and knowledge scores between the schools that do and do not take part in the EE programme, and showed that EE schools are mainly increasing their students' knowledge about the environment, without connecting that increase to a augmented affection for the natural world. Though the EE schools' self-declared primary EE aim is to work on the affective side, they seem to – unwillingly and unknowingly – have a cognitive focus.

CONCLUSIONS

Both instruments showed to be valuable in the context of evaluating EE in school. Based on the NEP results, the EE schools seem to be doing great work, if we look at the image the 2-MEV results show, than the picture becomes more nuanced. The NEP's one-dimensional approach to measuring the environmental worldview of children might be too straightforward and when used to evaluate EE programmes and lead to inflated conclusions. The 2-MEV on the other hand showed the link to the affective/cognitive divide and proved, for the EE schools, to be the more informative instrument.

franz.bogner@uni-bayreuth.de

ABSTRACT
We used the 2-MEV model of Bogner and Wiseman (1999, 2002, 2006) which is covering the two independent ecological values, Preservation and Utilization, in order to evaluate educational programs within a National Park by applying pre- and post-testing procedures. The model was developed in a series of studies, nationally and internationally, by proofing its validity for measuring adolescent environmental perception within a European context (Bogner 1998, 2000; Bogner & Wiseman 1997, 1998, 1999, 2002, 2004, 2006). Later on, the empirical model was independently confirmed by Milfont & Dukitt (2004, 2006) for an Australian population and by Johnson & Manoli (2009) for an American one. Thus, the model provides a valid empirical basis to evaluate educational programs within a National Park by applying a pre- and post-testing frame.

INTRODUCTION

Environmental problems nowadays are worldwide problems also requiring solutions at a global level. As a main cause of environmental degradation numerous authors identified the Dominant Western (Social) Paradigm (Dunlap & Van Liere, 1978, Disch, 1970, Milbrath 1984) which considers human-beings as separate and superior to nature as well as non-human creatures as important just proportionally to their usefulness (Gardner & Stern, 1996). This anthropocentric and materialistic world view includes the belief in economic growth building upon exploiting the seemingly ample resources and naively believing in technological progress that will solve any potential problems. This extreme paradigm is thought to be contrasted by an eco-centric worldview that gives nature an intrinsic worth and considers humans as part of nature. This so-called New Environmental Paradigm (Dunlap & Van Liere, 1978) or Deep Ecology Paradigm (e.g. Devall & Sessions, 1985) rejects environmentally destructive lifestyles and advocates a decrease in human population.

A general frame of values in the sense of important life goals as potential basis for anthropocentric or eco-centric attitudes and worldviews is a frequent study issue. According to Barnouw (1985), values (and attitudes, beliefs and behaviours), shared by a group of people and communicated from one generation to the next, correspond to the definition of culture. A good example within the context of environmentalism is the difference between Latin-American and Anglo-American worldviews as described by Deutsch Lynch (1993). Whereas the more anthropocentric and dichotomized Anglo environmentalism considers wilderness as "not been touched by the hand of man", sees the Latin environmentalism human-beings as integral part of nature rather than as its protectors and consumers. Studies comparing non-Hispanic with Hispanic respondents consistently described the latter as more concerned about the environment and more eco-centric represented by higher scores on the NEP scale (e.g., Noe & Snow, 1990).

The specific objective of this present study was to complement the “very little multinational environmental research” (Schultz & Zelezny, 1999). First, we extend the previous research with regard to the differentiation of environmental values by applying the Preservation and Utilization scales of Bogner and Wiseman (2002, 2006) and repeating the two-factor structure by explorative factor analysis.

DESIGN AND METHODOLOGY

Maximum likelihood factor analysis confirmed the two hypothesized orthogonal factors U and P of the 2-MEV model (Two Major Environmental Values) as sets of related attitudes. Thus, all participants could be allocated with regard to their scores in U and P by assigning them to quadrants including P+ and P-, U+ and U-. Consequently, due to the two test cycles changes within this allocation were monitored. The weeklong education program consisted of an extra-curricular unit in a field centre within a National Park.

RESULTS AND PROSPECT

The program caused a shift within the scale of environmental perception, preferable occurring in the consistent direction of favoring nature and the environment. Scores on the higher-order factor of Preservation (P) increased, those on Utilization (U) decreased (see figure below). Comparisons with the control group confirm the impact of the program. Differences between the pre-test scores of the control group and those of the treatment group were not significant; differences between the post-test scores were highly so. For both, the degree of change for the Preservation and Utilization scores to the pre-intervention scores, summarized as the regression line running through the cluster of points marking the position of each individual. In both cases, a clear regression downwards from left to right appears – the lower the pre-intervention score, the greater the degree of change. Furthermore, individual points cluster very closely about the regression lines, demonstrating a high degree of consistency in the positive effect produced by the intervention. Both shifts within our pre- and post-tested variables are discussed in the context of related studies using the same empirical survey instrument (Bogner, 1998, 1999, 2002; Bogner & Wiseman, 2004, 2006).

Particularly in the area of environmental education concern has always proceeded beyond the imparting of knowledge to changing adolescent attitudes, and even modifying their long term environmental behavior. The 2-MEV model yielded the further advantage that intervention studies throughout the series are comparable, since the core of the instrument has remained constant over decades.

TEACHING RADIOACTIVITY WITH THE AID OF THE MOVIE *MADAME CURIE*

Daniel Marcos Bonotto

Instituto de Geociências e Ciências Exatas / IGCE / UNESP / Rio Claro / Brazil

E-mail: dbonotto@rc.unesp.br

ABSTRACT

This paper evaluates some aspects that should be considered when using the movie *Madame Curie* movie as a didactic support for teaching radioactivity. Despite the cinema has been recognized since its earlier days as an important tool in people education due to its ability of telling histories by images, the teachers should promote opportunities for discussion in their classes of the views concerning to the scientist task and of some scientific aspects focused in the film.

Keywords: *Cinema, Education, Radioactivity teaching, Movie Madame Curie.*

INTRODUCTION

The cinema is a typical product of the occidental modernity and an amalgam of Art and Science, expressing a historical moment that forms a new aesthetical experience (Loureiro, 2008). Beyond the initial entertainment purposes, it was also started several relationships between education and cinema, as discussed by many investigators who recognized several films in formal and no-formal educative projects (Loureiro, 2008; etc.). Under this perspective, two different forms of cinematographic expressions (scientific and pedagogic nature) had occurred together and were frequently mixed in the beginning of the 20th century, despite, in the present days, there is a distinction between scientific cinematography (linked to the cinematography use for scientific investigations, their documentation and diffusion) and educational cinematography (associated to the cinematography use for general education and public instruction, where the cinema is utilized in the school environment) (Duarte & Alegria, 2008). There is an intense debate concerning to the fact that the role of reality is in no way the one of being copied, reproduced, or represented in the most truthful way, however, the “pedagogic vocation” of the cinema has been recognized since its earlier days as it allowed the use of news parameters to the art of telling histories by images, contributing to the people education, inclusive outside the schools (Duarte & Alegria, 2008). The purpose of this paper is to present the use of the movie *Madame Curie* (Flanklin & LeRoy,1943) for teaching radioactivity, pointing out some aspects related to science and scientific activity in a more appropriate view that the film show us.

METHODS

The radioactivity is a subject focused in many disciplines and a brief history of the film production is presented to the students before its exhibition. It is told to the students that following her mother's death, Eve Curie wrote a biography about her mother, after collecting and sorting various documents and letters left by Marie Curie, who discovered the radioactivity together with Henri Becquerel and Pierre Curie. The information, letters, and photographs she obtained were used in the writing of Marie Curie's biography, *Madame Curie,* published simultaneously around the world in 1937. Then, some information is provided about the 1930s decade (and most of the 1940s as well) for the cinema, as it has been labeled *The Golden Age of Hollywood*, although most of the cinema output of the decade was black-and-white. Afterwards, the steps of the film production are described, considering that in March 1938, Aldous Huxley was contacted by MGM for a writing contract in order to make a movie based on the book *Madame Curie* by the scientists' daughter Eve. The film *Madame Curie* was originally to star Greta Garbo and be directed by George Cukor, however, MGM ultimately rejected Huxley's script for it as "too literary". In 1943, the biography was finally adapted by MGM and released as a film having the performance of Greer Garson as Marie Curie, direction of Mervyn LeRoy and screenplay by Paul Osborn and Paul H. Rameau. After this initial historical information, some parts of the film concerning to the radioactivity and radium discoveries are exhibited to the students. Then, they are requested to express their opinions about them and many situations offer rich opportunities to discuss the conceptions of science and scientific activity showed by the film that are compared with those of the science educators nowadays consider as more appropriate (Sjøberg, 2004).

RESULTS

When the students are induced not to be mere film viewers but active thinkers on the messages veiculated in the parts of the film exhibited, a lot of questions arise. For instance, the film *Madame Curie* was heavily fictionalized for dramatic purposes and the discovery of radium appeared glamorous, following the typical formula of the Hollywood's films in that period, which was inspired on the big industries for producing automobiles, electro-domestics, canned food, etc. Such industrial organization was also applied to the production of films and involved (Loureiro, 2008): a big mode of production for realizing the films from the existing studium models, mitification of actors and actresses (star system), and adoption of the ruler code for the messages veiculated in the films in order to sustain the harmony between Hollywood and the institutions responsible by the moral maintenance in the USA society. The movie *Madame Curie* combined romance with edification, a sure-fire recipe for success in that era, so that the formula allowed it to receive seven Oscar nominations, including Best Picture, Best Actor, and Best Actress. Despite to be more historically accurate than most biographical films of its time, it omits any mention of Marie's family in Paris, including her sister Bronislawa, with whom she was very close, as well there is also virtually no mention of Marie's intense devotion to politics and the liberation/independence of her native Poland. This, obviously, would permit to recognize the strong links between the scientific activities and the social, political and cultural contexts that influence them. Additionally, the movie promotes opportunities for discussion with the students of the views involving the scientist task and of some scientific aspects focused in it, in order to clarify the actual achievements in the laboratory experiments held during the initial and following years of the radioactivity discovery. For example, Henri Becquerel himself reported the first observation of an effect of gamma rays on human tissue when, 10 days after he had carried a small amount of radium in his shirt pocket for 6 h, he got a kind of burn, which healed spontaneously in a few weeks, leaving a depigmented scar (Mazeron & Gerbaulet, 1998). Pierre Curie confirmed Becquerel's finding by deliberately applying radium powder on his forearm for 10 h and both published a paper in 1901 describing the physiological action of the radiation associated to radium (Mazeron & Gerbaulet, 1998). But the film makes no mention of these findings, as it contains scenes describing the burning effects only in Marie Curie's hand, according to the approach of the "star system" of the Hollywood's formula. It is also pointed out that even the Eve's book *Madame Curie* makes no mention to this aspect, as other health diseases with Marie Curie were described when experiments were realized in a "miserable old shed" from 1898 to 1902. Therefore, the film reinforces the view of the science constructed by solitary and missionary individuals situated above the society standards rather than the collective knowledge production subjected to right answers and mistakes. The movie is ended with a discourse attributed to Marie Curie, where the science is glamorously claimed as a big humanity benefactress, which is an ingenuous perspective that must be emphasized in the educational process related to Science Education.

CONCLUSIONS

The film *Madame Curie* has cultural and artistic values because it was well-filmed. It can be usefully utilized as a didactic support for teaching not only radioactivity but the science activity itself. However, situations like presented here must be critically analyzed in order to attend the Science Education purposes. The teachers must promote opportunities for discussion in their classes of the views involving the scientist task and of some scientific aspects focused in the film.

ABSTRACT

This paper is a description of an experience aimed at introducing an interdisciplinary approach in final grade of Brazilian elementary school. The aim is to show the transformation of the conception of space and time from the Aristotelian physics to the Einstein conception. These changes were accompanied by new visions of space and time both in Physics and Arts. The comparison between two expressions of human culture is used to introduce points of third culture (Snow, 1993).

Keywords: *science education, science and art, space and time.*

INTRODUCTION

The study of Physics in Brazil, in both elementary and high schools does not contemplate the developments of Aristotelian Physics and the Modern Physics. Aristotelian Physics is considered dead and Modern Physics presents many difficulties in using mathematical language. The purpose of this work is to understand the transformation of beliefs of the students about the nature of science from a course with a historical and philosophical approach, where science is seen as part of culture. In this approach, the new notion of space-time in Physics is compared with other contemporary cultural representations dealing with the same subject.

THE COURSE

A one-year Physics course was developed specially to deal with the study of space and time. The course introduced the latest three significant worldviews originated in Western civilizations and discussed the basics of the two transitional periods in between (Reis et al. 2001). These are extremely rich periods for the argumentation that arose, and also because they normally go beyond the scientific field (Fleck,1986).

During the first period, the transformation of the Aristotelian to the modern world view was discussed, and the shift from a closed to an infinite universe. This view was studied, as well as the planetary models of Ptolemy, Copernicus, Brahe, and Kepler. Within this stage, the basic classical mechanics notions were introduced: Kepler's Laws, Newton's Laws, including the universal law of gravitation.

As artists and scientists shared the same cultural environment, it was discussed what was happening concerning art back then. So aggregate space in medieval paintings was compared to the new idea brought by the discovery of perspective, whereby it was possible to go from a closed to an open space where infinity could be conceived (Edgerton Jr, 1993). This was done by projecting medieval frescoes and Renaissance paintings.

During the second period, when this activity was carried out, we introduced Einstein's new concept of space-time. Here, the students noticed the change in the world view and the new construction of gravitation based on space-time curvature.

In this transition period, new scientific ideas were introduced as part of a deeper transformation *(Galison, 2003)*. At this point, art came into play. Paintings by Claude Monet where the same scenerey was painted several times at different times were presented to students (Shlain, 1991). The new conception of space from Picasso illustrated the transformation in the art. In literature, at the end of Eighteenth century, H G Wells (1992) wrote the "Time Machine", where a scientist presents a new space-time conception.
During all course basic mathematical tools were used.

THE METHODOLOGY OF RESEARCH

The course was applied at a school in Rio de Janeiro during 36 weeks to 14-15 year-old students. The teacher had 50 minutes a week to work with them. The teacher occupied the time presenting the subject, correcting the exercises and applying the evaluations. There were 180 students divided into 5 classes.

The research was qualitative methodology. All data were collected by the teacher with a ethnographic view. The teacher wrote his observations after classes in a diary where he added his comments too. In this diary, statements of several students and their dialogues with the teacher were recorded. Each week, all observations recorded in the diary were discussed by a group of academic researchers and teachers. The group evaluated the process during it application.

RESULTS

After applying this course during two consecutive years, it was possible to reach the conclusion that this approach shows a new way to learn Physics. Some students feel uncomfortable with the fact that theories change over time. This situation showed that it is very important to focus the courses in the specific transition moments, or, as Kuhn's (1963) put it, in the revolutionary moments. For instance, when the teacher started presenting Einstein's model of spacetime to explain the new vision about gravitation, a student asked him:

> "You are going to explain another model? Why did you start the explanation with this model, since it is the right one?" (student)

The belief about absolute and immutable truth has been broken. They were starting to understand the nature of science. The students understood science as a process. This can be clearly seen with another question brought by them:

> "How to know that this model is the last model? The truthful model!" (student)

On the other hand, the relationship between science and art has also brought a new vision about the construction of scientific knowledge. Scientific models were perceived as creations of men and women by means of their relationship with nature. But this approach led students to know that scientists don't work out of the world. Their creations dialogue with others areas of knowledge and values. Metaphysics is part of the construction of knowledge. Scientific construction dialogues with religions, philosophy, and arts.

CONCLUSION

This research has been intended to know the student's conceptions about nature of science through relationships between science and art. In the coming years we intend to construct a picture more detailed from these conceptions and their transformations. It was clear that there is a need for deeper understanding through a survey on a larger scale. The relationship between science and art is a good way to know how can be transformed the student's belief about the construction of scientific knowledge.

ABSTRACT

In this paper we document the use of the SCALE Immersion Model for Professional Learning (SIMPL™) to analyse an innovative initial teacher education program for prospective science teachers in South Africa learning to teach argumentation, a designated learning outcome in the national curricula goals of the country (Department of Education, 2002). Data were collected as field notes from observations of teaching sessions and interviews with course tutors. Facilitated reflections using SIMPL helped course tutors separate professional and student learning and realise that student teachers' own comprehension and experience of how to argue had been underestimated.

Keywords: *Argumentation, teacher education, curriculum development*

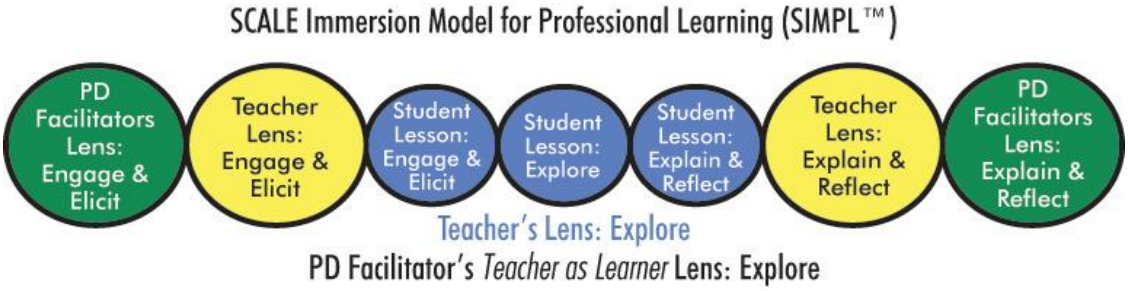
INTRODUCTION

In South Africa, an outcomes based curriculum places critical thinking at the heart of teaching in all subjects. Since argumentation, the process of arguing, has been recognised as a key component of critical thinking (Facione, 1990) and as essential to the development and teaching of ideas and theory in science, the teaching of argumentation in science has received much attention in the scientific community in research and in the development of curriculum materials (Jimenez and Erduran, 2008). So far in South Africa research has concentrated on the nature of teachers' argumentation (Scholtz *et. al,* 2008), learners' argumentation abilities before teaching (Lubben *et al*, 2009) and the different argumentation outcomes of scientific and socio-scientific contexts for lessons (Braund *et al*, 2007). Studies show urgent need for teachers and learners to have better appreciation of what is meant by and required of good quality argumentation in science and technology, the inherent complexities and differences connected with using various contexts for argument and the social, cultural, political, ethical and religious implications of argumentation that are particularly relevant in multi-racial classrooms. Consequently it was recognized that there is a need for teachers entering the profession to be better versed in argumentation and critical thinking and so the focus of research has turned to teacher education.

METHODS

The SCALE Immersion Model of Professional Learning (SIMPL™) was developed in the U.S. to help teacher educators gain new understandings about science and mathematics content and pedagogy in the processes involved in educating future science and mathematics teachers (Lauffer & Lauffer, 2009). Reflections on a semester-long programme on teaching argumentation taught in the final year of a BEd course using SIMPL were carried out to explore how prospective science and technology teachers learn to teach argumentation and what match there might be to components of SIMPL in domains of students', teachers' and PD facilitators' (course tutors) growth in professional learning.

Figure 1. The SIMPL™ Model



Data were collected from two sources: (1) reflective field observations of a semester course on the process and pedagogy of argumentation taught to final year BEd students made by one of the authors who was a fullbright scholar attached to the university and: (2) through recorded interviews with course tutors of science and technology method components of the course. Using SIMPL the study looked for areas of congruence between the module teaching, student outcomes and SIMPL components thus areas in which SIMPL informed the module and its implementation or *vice versa*, i.e., outcomes raised questions about SIMPL. Research was able to comment on the effectiveness of the course at the same time as having facility to critique the validity and applicability of SIMPL in a new setting – South African teacher education.

RESULTS

The application of SIMPL in reflective analysis showed that student teachers need more input in the didactics of augmentation, increased breadth of experience in socio-scientific and scientific contexts in which to develop their argumentation and improved appreciation of class structuring techniques for effective group work. SIMPL proved useful in helping teacher educators appreciate the complexities of their roles and showed a need for and examination of the pedagogy of teacher education that includes more empathy with student teacher learning and recognizes the various lenses of learning involved; for the students, for the school pupils they teach and, most crucially, for the teacher educators.

CONCLUSIONS

The validity and usefulness of SIMPL as an analytical tool for reflective analysis of pedagogical structure and effectiveness of ITE university-based programs in a South African context is supported. As a result of the research, teacher educators are more aware of their multi-level roles in preparation, and diagnosis in ongoing course development and have included more time for student reflection on the development of their argumentation abilities and as contribution to more general construction of their knowledge in earlier years of the degree course. The pay-off for the current cohort of students is better self-awareness of their learning through better appreciation of the value of critical thinking and a willingness to communicate ideas about what teaching for critical thinking and argumentation entails for learners they will teach.

EMERGING SCIENCE IDENTITIES IN A MENTORSHIP PROGRAM

Lars Brian Krogh

Hanne Møller Andersen

Centre for Science Education, Aarhus University, DK

hanne.moeller.andersen@cse.au.dk

ABSTRACT

The emergence of students' science identity has been investigated in a university science mentorship program by interviews, questionnaires and observations. The target group consisted of 14 upper secondary school students, all having some inclination towards science and most of them coming from backgrounds far from academic science. Using Late Modern identity theory as a lens, we have constructed and analyzed students' identity narratives. All students in our sample had highly compatible images of scientists and conceptions of themselves. However, their identity process orientations differed and a number of distinct emerging science identities were found.

Keywords: *Science identity, mentorship program, narrative, recruitment*

INTRODUCTION

Danish youth is a clear-cut example of the "Science-is-important-but-I-won't-be-doing-it" trend" emphasized in recent reports (e.g. OECD Global Science Forum, 2004). The intriguing question is how students' general acceptance of the importance of science as an enterprise may lead to internalization of science as part of their personal identity project.

Reports (e.g. (OECD Global Science Forum, 2004)) have been advocating mentoring programmes as a way to facilitate border crossing into S&T paths, providing first-hand-tertiary science experiences, richer and more valid images of science and science careers, as well as relations to useful role-models. The overall aim of our longitudinal project is to study how participation in such a 1½-year mentor program interferes with students' identity processes and may facilitate their emerging science identities and their recruitment to university studies. However, the present work will focus on results from the early phase of the mentorship program. Our research questions here will be:

- Q1 (*descriptive):* What are students' narratives in relation to science and academic education? How do their images of scientists correspond with their characterization of actual and potential Selves?
- Q2 *(analytical):* How can Late Modern identity theory contribute to the interpretation and understanding of student identity narratives in relation to science and academic education?

Theoretically, we subscribe to a Late Modern conception of identity (e.g. Cote & Levine, 2002), where identity is seen as a dynamic narrative of Self (e.g. Sfard & Prusak, 2005). Particularly, we draw on Sfard & Prusak's analytical distinction between *actual* and *designated* identities ("stories believed to have the potential to become part of one's actual identity"). Further, we transcend the identity state description afforded by Marcia's Identity Status Theory (Marcia, 1980) to hypothesize a dynamic description of adolescents' trajectories in and out of science, emphasizing three *Identity Process orientations*: *Exploring, Self-reflecting,* and *Committing*.

METHODS

From a total of 100 mentorship-students we have sampled a diverse target-group of 14 students on the basis of students' written applications to join the mentorship program. A rich empirical database has been gathered, but the present work is based on student interviews and questionnaires. Both interviews and questionnaires focused on students' images of science and scientists, their ideas about future education in relation to science and university, their science related self-efficacy and experiences with science both in and out of school, and the attitudes of family and friends in relation to science and university studies. The interviews were individual, semi-structured and typically lasted for about an hour. The last part of the interview included a simple *"Scientists And Me"* (SAM)-instrument, which was designed to elicit a gap between students' conceptions of scientists and themselves.

All our target-students completed a questionnaire consisting of 76 items, with major parts taken from existing surveys (e.g. attitudinal scales from PISA Science 2006).

Our first analytical step (cf. research question 1) has been to construct and validate narratives for each target student, pursuing our theoretical understanding of identities as narratives. The narratives constructed on the basis of students' self-presentations (interviews, questionnaire) have been triangulated against observations of the students in different mentor program activities. The SAM-data has been analyzed separately, and significant features have been built into students' narratives. Draft narratives were member-checked with the participating students.

Following this step we have analyzed students' narratives in terms of categories from identity theory, e.g. to establish their actual/designated identities in relation to science and how *Exploring*, *Committing* and *Self-reflecting* students are in educational choice related life-domains, including science.

RESULTS

We have found students' narratives to be rich and multi-facetted. Illustrations of this and the nature of narratives will be given at the presentation. The "potential scientist" status of students in our sample is evident from consistent patterns of the SAM-analysis. Even though the sample is more homogenous than samples in other science identity studies we have identified significant differences among emerging science identities. Table 1 indicates two examples of emerging science identities in terms of our theoretical lenses (Actual Identities (ai) and Designated Science Identities (di) and dominant Identity Process-Orientations (ipo))

Table 1. Sample emerging science identities through theoretical lenses

T (boy) has an interest in Math, Science and Technology (MST) (ai), and he wants a MST-education, but he is uncertain about going to the university (di). T sees scientists as nerds as well as interesting persons, because of their specialist knowledge. He experiences no serious gap in taking on a MST scientist identity. T is oriented towards *Exploring*. He is easily inspired by new information and he is willing to change his ideas about the future if something new seems challenging (*no commitment*). He is rather *reflective* in his description of his life, both concerning his per sonal characteristics and possibilities	**F** (girl) has an interest in math and science – as well as several other subjects (ai). F plans going to university (di), but she is uncertain about what she wants to study. F sees scientists as curious and innovative, and she finds it interesting to listen to their stories. She thinks that scientists work collaboratively, but ascribe them low political and social interest, which may prevent her from choosing science (di). F's is oriented towards *reflecting* and social relations. She is highly influenced by ideas and recognition from significant others (parents and teachers). She is not *Committing herself* in relation to future job or education, and is not seriously *Exploring.*

CONCLUSIONS

The students of our study typically have varied and low-stereotyped images of scientists, and the overlap between students' actual and designated science identities are considerable. Science indeed is a potential identity-story for this group of students, though some value-differences have been identified, that may ultimately lead students away from science trajectories. Students' narratives have been analyzed in terms of their orientation towards the identity-processes *Exploring, Reflecting,* and *Committing* in life-domains of relevance for science. It is hypothesized that these orientations will critically and differentially impact students' response to the mentorship program and their ways in or out of science. Another question is how external affordances and incentives from the mentorship program and school science facilitate *Exploring* etc. We will know more as our study proceeds.

ABSTRACT

The purpose of this study was to determine the preservice science teachers' (PSTs) metacognitive processes by using metacognitive prompts in a science laboratory course. The data were obtained through PSTs' laboratory reports which contains metacognitive prompts and PSTs' models developed based on their observations and inferences. PSTs were formed 8 groups each included 3 to 4 students and two groups were randomly selected for the analysis of this study. The data were analyzed through qualitative methods. It was found PSTs, who activated their procedural knowledge, constructed effective models which enabled them to carry out necessary investigations during the laboratory activities.

Keywords: *metacognition, metacognitive prompts, preservice science teachers*

INTRODUCTION

Metacognition is the ability which provides one to understand and monitor the cognitive processes (Zimmerman, 1989). Two basic types of metacognition are executive management strategies for planning, monitoring, evaluating and revising one's own thinking processes and products, and strategic knowledge about what information and strategies/skills one has (declarative), when and why to use them (contextual/conditional) and how to use them (procedural) (cited in Hartman, 2001; Flavell,1987).

Use of metacognition is necessary for learning since metacognitive knowledge and strategies have important roles in thinking, reasoning and problem solving. Although the studies on metacognition show that metacognition has an important role on learning, many srudents are unaware of their thinking processes, strategies and their thinking products. (Driver, Newton & Osborne, 2000).

In this study metacogvitive prompts are used. Prompts are questions that encourage students to add more details and ask for thinking deeply to evoke metacognitive skills (Peters, 2008). These prompts help students to write their metacognitive reflections which includes their learning process, strategies, comprehension levels, their success or failure in their tasks and the evaluation of their performance (Bangert-Drowns, Hurler & Wilkinson, 2004). Therefore, prompts were given students to evoke their metacognitive skills.

METHOD

The participants were preservice science teachers who attended an inquiry based laboratory application course in a large public university in Ankara, Turkey. Totally 29 PSTs took this course and they worked as a group of 3 or 4. Of these groups, 2 groups were selected randomly to for the purpose of this study. Since each of these two groups included 4 PSTs, 8 PSTs constituted the particpants of this study. All PSTs in this study were 3rd graders and they took the same background lessons. The data were obtained through the PSTs responses to the laboratory reports, which included metacognitive prompts. 6 activities were covered throughout the course and an activity was selected to focus for this study. This activity's name was black box which was designed by Lederman and Abd-El-Khalick (1998). For this study metacognitive prompts and model request were added to this activity. Through developing a model the researchers tried to understand alternative working models of the black box that appear on particpants' minds during the activity.PSTs' strategies for designing their own model and their knowledge of cognition were examined with respect to metacognition.

The analysis was made through content analysis techniques as one ofthe qualitative analysis techniques. For this purpose PSTs' written responses to laboratory methods were examined with respect to content.

PROCEDURE

Balack box activity provides students to make observations and inferences. It is a closed box and there was a system in it which provides more liquid than one added (Lederman & Abd-El-Khalic, 1998). In this study, PSTs drew their own model individually depending on their observations and inferences. The purpose of this activity was the distinction between observation and inference, the importance of subjectivity, creativity in science. The activity was completed in three hours.

RESULTS

Answers for observation and inference:

Some examples for observations from their answers are: *200 ml transperant liguid is poured from the top of the box and 550 ml homogenous transparent liquid is taken. Box have one entrance from the top and one exit wit a pipe in the bottom.*
Some examples for inferences from their answers are: *There are some liquid in black box. There is a system in the box which is designed for the release some amount of liquid.*
Examples show that students know the differences between observation and inferences.

The prompt for observation and inference was "What do you coclude about the value of observations and inferences in the scientific method?" Duygu wrote that *"In order to make hypothesis, observations and inferences are important for science. Scientists use observation to make their inferences and make prediction with using their inferences. They make hypothesis by using their prediction."* In terms of metacognitive statements, she explicitly refers her undertsanding and knew why to use observations and inferences. It shows that she used conditional knowledge. Students knew the difference but they did not refer how they make inferences and how scientists make inferences.

Prompt for their models is that "What experiences gave you ideas to help you make sense of your model?" The question requires procedural knowledge which is a type of cognition of knowledge in metacognition. PSTs who activated their procedural knowledge wrote those answers. Burcu wrote that "*the rivers flow due to the potential difference . In my model, I tried to create a big potential difference between 2nd beaker and the hole, so it caused the flow of water from the hole".* Mehmet wrote that *"Im inspired by the work of dam that so much amount of water is activated by opening of barier. Because water which is behind the barrier pushes the water in dam after barrier open. Here, I thought opening of barrier as tearing of paper. Increasing pressure both of two event leads flowing huge amount of water."* Esra draw a model based on her chemistry knowledge and wrote that: *" In chemistry labs, I observed* *the elements which are solving eachother while the others do not solve. In this model, I thought that there is a material which is solved with water and is not solved with colorless liquid."* These students' models were logical and capable of work. On the other hand, there are other students who did not activate cognition of knowledge. These students' models were not capable to work. Aslıhan was one of them and wrote that *"my previous knowledge and physics and chemistry lessons help me make sense of my model."* She did not refer any metacognitive statement in her answer. As a result, PSTs are aware of the differences between observation and inference but most of them did not aware of the metacognitive skills. It is also concluded that PTSs who activated metacognitive skills created models that are capable to work.

ABSTRACT

Teaching Mendelian genetics to high school students is rather a complicated process that requires a diligent planning and appropriate materials. The aim of this study was to use virtual courseware in order to implement an inquiry-based genetics teaching. A teaching unit that required students to design experiments and collect, analyze data, and test hypothesis was designed. A "Drosophila" lab from Virtual Courseware for Inquiry-based Science Education was used in pretest-posttest control-group experimental research design. It was concluded that an inquiry-based teaching method with "Drosophila" simulation is possible, beneficial, and has a potential to support conceptual learning of principles of inheritance.

Keywords: *Mendelian genetics, virtual courseware, inquiry-based teaching.*

INTRODUCTION

The use of learning technologies to support students in developing conceptual understanding of a specific subject-matter is a viable use of technology. Learning technologies can also be used to enhance some of the cognitive processes that have been associated with inquiry in science, including generating ideas, coordinating ideas with evidence, evaluating findings, and weighing alternative explanations. One area of biology in which students have difficulties is genetics (Johnson & Stewart, 2002). Most school textbooks introduce Mendelian genetics and the discussion of mathematical models of transmission patterns. A survey of high school teachers (Stewart, 1982) indicated that Mendelian genetics, meiosis and mitosis, and the chromosome theory of inheritance were considered among the most difficult as well as the most important topics of study for high school students. This research focuses on high school students' learning in Mendelian genetics using computer simulation.

By examining learning processes of students as they interact with computer simulation, and the guidance strategies that facilitate their learning in this study, we may be able to gain some insights into how to feasibly integrate computer simulations into high school biology classrooms in order to enhance meaningful and conceptual learning.

THEORETICAL BACKGROUND

Perspectives from social constructivist and socio-cultural views of learning shaped this study (Vygotsky, 1978; Wenger, 1998). According to this line of thinking, science learning can be viewed as a participatory process that includes the negotiation of the cultural practices of scientific communities. These cultural practices include constructing explanations, defending and challenging claims, interpreting evidence, using and developing models, transforming observations into findings, and arguing theories. In this framework, learning is regarded as a participatory process in which the learner gradually becomes an active member in a cultural community by learning its discourse practices, norms, and ways of thinking (Wenger, 1998).

Hypothesis testing has recently been presented very positively within the science education community, being promoted as a powerful context for supporting knowledge acquisition in science (Howe et al., 2000). The drive has come from reform documents, which emphasize the integrated acquisition of conceptual and procedural knowledge. Because hypothesis testing provides context where students can formulate conceptual knowledge into researchable ideas, investigate ideas through manipulation, prediction, and observation, and evaluate ideas in the light of evidence, in principle, should allow integrated acquisition of knowledge.

METHODS

"Drosophila" is an interactive, online simulation which was developed in Virtual Courseware for Inquiry Science Education project and designed to enhance traditional high school biology curricula by providing supplements to experimental laboratory in California State University. Students make observations, propose hypotheses, design experiments, collect and analyze data generated by the simulation. Drosophila Lab allows the recording of observations, data, and results. This is manifested as a built-in electronic notebook or journal. Thus, the online user interface exhibits the entire process of science from discovery, to analysis, to reporting.

Pretest-posttest control-group experimental research design was adopted in this study which was conducted in Bostancı Doga High School. There were total of 88 high school students in two experimental and two control group classrooms. Two experimental group classes received inquiry-based teaching with VCISE program and two control group classes received traditional lecturing. Unit was completed in 8 hours of instruction. All tests and questionnaires were given to all participants. Students were assessed using pre- and post-tests and concept maps. Additionally, participants were given another general test for grading purposes. Students were also given surveys to measure their learning preferences and evaluate their own learning. Appropriate statistical methods employed in data analysis.

RESULTS

There was not any statistically significant difference between pre-test scores of experimental and control groups. However, a statistically significant difference detected between post-tests of experimental and control groups. In addition to posttest, an academic achievement test which consisted of classical paper and pencil items was also administered to all groups for grading purposes. There was statistically highly significant difference between the means of achievement test scores of experimental and control groups. Qualitative analysis of concepts maps and student interviews revealed important findings. Concept maps of experimental group received higher grades as they were more structured and hierarchically correct and included more concepts and linkages. Concept maps, posttest, and achievement test scores were highly correlated. Inquiry-based learning experiences with virtual courseware, Drosophila, not only facilitated conceptual genetics learning but also provided an excellent opportunity for students to develop inquiry abilities such as hypothesis testing and experimental design.

CONCLUSIONS

It was concluded that an inquiry-based teaching method with “Drosophila” simulation is possible, beneficial, and has a potential to support conceptual learning of principles of inheritance. In our contribution we will report our results and describe instructional measures and scaffolds that rendered inquiry teaching effective. Drosophila software has “Notebooks” where students could take notes about their hypothesis and inquiry. Analysis revealed that students barely used notes to reflect on their own learning process. They rather haphazardly followed the instructions and did not really engage cognitively in the process. The importance of systematic note taking and data recording was emphasized. Interpreting their own experimental outcomes served as instructional scaffold in their conceptual development.

ABSTRACT

Education carries inexorably the notion of values to be transmitted, often expressed in an implicit way (Reiss, 2007). Being health a matter of social and individual challenges, health education (HE) is a process involving strongly the education for the values. Schools must assume this role of education for the values and should also identify their students' conceptions. Thus, the general aim of the present study was to identify the system of values manifest, explicitly or implicitly, in national and international publications. Six axes of values were identified: Social–Individual, Salutogenic–Pathogenic, Holistic–Reductionist, Equity–Inequity, Autonomy–Dependence and Democratic–Autocratic. To know how different university courses in the area of health (medicine and nursing), pre-school teaching, basic teaching and social service highlight these axes of values, we applied a questionnaire to 709 students of the above seven courses. Particular attention was given to the course of nursing located in Vila Real (E-VR). Results showed that the E-VR teaching modules programmes and the corresponding teaching documents refer almost solely the Salutogenic/Pathogenic axis, minimising all the other five axes of values. Having in mind the effects of the training courses in student's values and conceptions about health education and health promotion (HE/HP), this study reveals that in most courses (including E-VR) more emphasis should be given to the social aspect and the salutogenic perspective of HE/HP.

Key words: *Health education, Values, University training.*

INTRODUCTION

According to the World Health Organisation (WHO, 2000), governments have the responsibility to promote their citizens' health. In order to fulfil this aim they should guarantee that the professionals of all sectors acquire appropriate knowledge, attitudes and competences to protect and promote health (WHO, 2008). Besides, no educational plan should avoid values, since they are the elements that shape up most people's choices (Vallejo, 2002). For that, universities must assume this role of education for the values and should also identify their students' conceptions. Thus, the general aim of the present study was to analyse the evolution of students' values and conceptions about health education (HE) and health promotion (HP), through their university training. These students were enrolled in the 1st and 4th year of university courses: four courses in the field of health (1 of medicine and 3 of nurse practitioners) and three in social/educational studies (social service, pre-school teaching and basic school teaching). Particular attention was given to the course of nursing located in Vila Real (E-VR). To carry out this evaluation, it was created previously a theoretical framework concerning the axes of values on health education, which was constructed by content analysis of research papers and international organisations documents.

METHODOLOGY

Theoretical framework on axes of values on health education

Content analysis was carried out in a total of 129 documents: in 66 papers from research authors (46 books and chapters of books and 20 papers in journals); in 30 official documents from international organisations (8 from the WHO, 5 from the European Commission and 17 from the International Council of Nurses); in 33 Portuguese organisations (5 from the government, 8 from the Ministry of Health, 8 from the Ministry of Education, 6 from the Ministry of Science, Technology and Higher Education, and 6 from the Nurses' professional body).

The axes of values emerged from the analysis of health education documents, by using the method of "ground theory" (Strauss & Corbin, 1998) were applied to the analysis of texts used at one of the university courses of nursing (E-VR) and for the preparation of the questionnaires to be applied to the university students of the seven courses analysed in this study.

Theoretical framework on axes of values on health education

A questionnaire was constructed and validated after a pilot test (Carvalho & Carvalho, 2006). The population size was 1132 students (year 1 and year 4) and the sample was composed of 709 students (62.6% of the population) of seven university courses: E-VR – Nurses from Vila Real (UTAD); E-BR – Nurses from Braga (UM); E-PO – Nurses from Porto (IPP); MED – Medicine from Porto (UP); PEB – Primary school teachers (UM); EI – Kindergarten educator (UM); SSO – Social services (UC-B).

RESULTS

Theoretical framework on axes of values on health education

Through the content analysis of health education and health promotion (HE/HP) documents we identified a set of six axes of values in HP/HE: Social–Individual, Salutogenic–Pathogenic, Holistic–Reductionist, Equity–Inequity, Autonomy–Dependence and Democratic–Autocratic.

Asking students of the seven courses to express in single words their ideas about health, the key words emerged were (by decreasing order): Well-being, Hospital, Disease, Doctors and Nurses. The predominance of these key words is connected to a reductionist vision of the health determinants, centred in the system of health, excluding the other ones.

When looking at the evolution of the concept of health from the 1st to the 4th year of university training, the Braga Nursing course (E-BR) was the one with higher decrease in the key words associated to the reductionist vision of the term and, similarly, the course of Basic Teaching Teachers (PEB) was the one with more increases associated to the wide concept of health.

In contrast, the nursing course from Vila real (E-VR) did not show substantial changes on the perspective of health, keeping the technical-centric view of health along training. Training showed to strengthen the construction of a wider HP concept in the E-VR and in the Porto Nursing course (E-PO), with highly significant differences (χ^2: p=0,000) from the 1st to the 4th year. The majority of the sample (87%) considers that HE has values to promote; being the concept responsibility the most indicated one.

Taking together all samples it was possible to verify that the training caused statistically significant evolution on the conceptions in the following three axes: from pathogenic to salutogenic; from reductionist to holistic; and from autocratic to democratic. No changes were found in the axes social/individual, equity/inequity and autonomy/dependence.

A general tendency towards the positive poles of the values axes was found in most sub-samples: the highest scores were found in the courses E-BR and Medicine (MED) whereas the smallest means were in the Social Service course (SSO).

CONCLUSIONS AND IMPLICATIONS

The university (E-VR) teaching modules programmes and the corresponding teaching documents refer almost solely the Salutogenic/Pathogenic axis, minimising all the other five axes of values. The present study demonstrates that changes in the programmes should be made in order to follow the international guidelines on HE/HP.

Having in mind the effects of the training courses in student's values and conceptions about HE/HP this study reveals that more emphasis should be given to the social aspect of HE/HP (in E-VR, E-PO, MED, PEB, EI and SSO), to the salutogenic perspective (in E-BR, E-PO, PEB, EI and SSO), to the holistic view of health (in EI), to the Equity in health (in E-VR, E-PO and EI) and to autonomy and democracy (in MED and EI).

ABSTRACT

This study aims to explore Turkish ninth grade students' interests in learning physics topics and physics-related out of school experiences in terms of gender differences. The questionnaire-based Relevance of Science Education (ROSE) Project data of 9th grade students were collected in Turkey from 1,260 students. Statistical analysis included tabulation of frequency distribution, descriptive statistics, MANOVA and correlation analysis. The findings of this study revealed that Turkish students are interested in learning physics topics, but they have little out of school experiences related to physics. Several significant gender differences were found. Based on the findings, the implications for physics education will be discussed.

Keywords: *Interests, out of school experiences, physics topics.*

INTRODUCTION

Many studies have been conducted on students' behavior, interests and attitudes toward science / physics (Sjoberg, 2000; Osborne, Simon & Collins, 2003) in the last 20 years. Pupils' interests in Physics from ROSE study also researched by Lavonen et al. (2005, 2008) and Trumper (2006). According to literature on the students' interest in physics context, girls mean scores were typically lower than boys. However, it is found that girls are more interested than boys in phenomena that is not explained by school physics, and nature values and environmental responsibility (Lavonen, et al., 2005; Hoffman, 2002; Cavas et al., 2009) The main message from ROSE based studies tell us that it is important to re-design curriculum combining interesting science topics. This concern is vital not only for lasting scientific endeavor but also for sustaining scientific literacy. The aim of this study is to investigate Turkish ninth grade students' interests in learning physics topics and physics-related out of school experiences regarding gender.

METHOD

In this study, a comparative study's questionnaire, ROSE (Relevance of Science Education), was used as a data collection tool. ROSE questionnaire is a Likert-type scale and "What I want to learn about" "My future job", "Me and the environmental challenges", "My science classes", "My opinion about science and technology", "My out-of-school experiences" and "Me as a scientist requires students" sections. In this study, we used 29 items related to physics topics from "What I want to learn about" section and 21 items related to out of school experiences in physics from "My out-of-school experiences" section of the ROSE questionnaire. Students' interests in learning physics topics were analysed into four contexts categorized by Schreiner and Sjoberg (2004). These contexts are "*Astrophysics & Universe (AU)*", "*Light, Colours and Radiation (LCR)",* "*Sounds (S)"* and "*Energy and Electricity (EE)"*. The sample of this study includes 680 girls and 580 boys enrolled at ninth grade of the 63 high schools from 21 cities which are located at seven different geographic regions in the 2003-2004 teaching semester. The national average school age of the students is 15 years.

RESULTS

In order to evaluate the reliability of the sub-scales, we calculated Cronbach's Alpha (α) for each scale. The reliability coefficients for the "What I want to learn about Physics" and "My out-of-school experiences" scales were found as 0.88 and 0.83 respectively. Mean scores and standard deviations for girls, boys and overall can be shown at Table 1.

Table 1. Descriptive Statistics for Students' Interests Scores

	Girls		Boys		Total	
	Mean	**SD**	**Mean**	**SD**	**Mean**	**SD**
Astrophysics & Universe (AU)	3.17	0.58	3.03	0.63	3.11	0.61
Light, Colors and Radiation (LCR)	2.86	0.56	2.78	0.61	2.82	0.60
Sounds (S)	2.83	0.76	2.73	0.75	2.78	0.75
Energy and Electricity (EE)	2.74	0.73	2.98	0.62	2.85	0.70
Total (AU, LCR, S, EE)	**2.96**	**0.49**	**2.90**	**0.53**	**2.93**	**0.68**
Out of school experiences	**2.05**	**0.47**	**2.40**	**0.52**	**2.21**	**0.52**

Results indicate that students' interests in learning physics topics are at a moderate level (M= 2,93, SD= 0.68). Students show more interest in learning astrophysics and universe subjects than other topics. Interestingly, girls are more interested in learning physics topics than boys except one topic (energy and electricity). Students' out of school experiences related to physics topics are analyzed in terms of gender. Generally mean scores of out of school experiences in physics for both girls (M=2.05) and boys (M=2.40) are under middle of the scale (2.5). Students only have several experiences in using binoculars and camera, measuring the temperature with a thermometer and using a measuring ruler, tape or stick. They had little experience in charging a car battery, using mechanical devices like a windmill, watermill, and waterwheel, compass and visiting informal science settings like science centers or museums. In order to find differences between girls and boys' mean scores of interests and out of school experiences in terms of physics topics, one-way MANOVA was utilized. Significantly differences were found in both students' interests in learning different physics topics and out of school experiences related to physics (Wilks' Λ= 0.81, $F(1,1258)=58.51$, $p=0.000$, partial eta squared= .189). While girls have higher mean scores than boys in learning AU, LCR and S, boys are more interested in learning EE and experienced in physics. There is also a significant small but positive relationship between students interests in learning physics topics and physics-related out of school experiences ($r=.288$).

DISCUSSION

It is well known fact that students' interest and experience affect their motivation and success in learning. Therefore all teaching activities should be designed regarding these factors. However, there is a important gap between what is learned in the classroom and the real life context of the pupils' present or future world (Anamuah-Mensah and Towse, 1995; Stevenson, 1995 and Muskin, 1997, cited in Anderson, 2005). Like many others, our study also show that both girls and boys are very interested in learning physics topics but they have no chance to experience physics-related out of school activities. In order to solve this problem, science curriculum or context should be developed taking into account students' out of school experiences.

ABSTRACT

This study investigated prospective early childhood teachers' conceptions of nature of science (NOS) and scientific inquiry (SI). The participants comprised 119 undergraduate students enrolled in an early childhood education program in a university in southern Taiwan. Two open-ended questionnaires, coupled with individual semi-structured interviews, were used to separately assess the participants' views of NOS and SI. The results indicated that almost all the participants possessed inadequate conceptions of NOS and SI.

Keywords: *nature of science, prospective teacher, scientific inquiry*

INTRODUCTION

Scientific literacy for all citizens is an important goal of science education in many countries, and developing an adequate understanding of the nature of science and scientific inquiry is a key element in achieving this goal.

METHODS

This study comprised 119 undergraduates studying early childhood education in a university in southern Taiwan. Two open-ended questionnaires were used to independently assess the participants' views of NOS and SI. Semi-structured interviews further established the face validity of the questionnaires by ensuring that the researchers' interpretations corresponded to those of the participants.

RESULTS

The results revealed that very few of the participants possessed adequate conceptions of all aspects of NOS and SI. However, compared to those in previous studies (e. g., Liu, & Lederman, 2007) the majority of participants in this study evidenced inadequate conceptions of most target NOS and SI aspects.

CONCLUSIONS

Since teachers' conceptions of NOS and SI may influence their teaching practices, the present results indicate a need for prospective early childhood teachers to develop a better understanding of the nature of science and scientific inquiry.

ABSTRACT

Science contains some very important disciplines that contribute to the further development of our society. We focused on the problem of creating of contents and educational methods of science subjects which will help to improve the pupils' interest in these subjects and to increase the effectivity of their teaching.

This contribution informs about the solution of this problematics in the national and European projects aimed, among other, to increasing the interest on primary and secondary school pupils in science via interesting contents, current themes emphasizing their practical applicability and use of new activizing methods of these fields, especially the inquiry-based science education.

Keywords: *primary and secondary schools, science subjects, key and specific competences, science literacy*

INTRODUCTION

The turn of century's international comparative studies in science education showed that the young people have much less interest in studying science. For example, the pupils of primary and secondary schools in most of the countries of Europe and beyond, don't have much interest in the science education and subjects like physics and chemistry are actually the least favorite subjects in the long term on these schools. The way science is being taught in schools is justifiably considered one of the main cases of the dropping interest (Abd-El-Khalick, 2005). Experts are trying, as part of their national and international projects, to stop this situation; their goal is to analyze the current national initiatives in a given field and get know-how elements that could cause a substantial change in young people's interest in studying science and that could be transferrable and usable in the educational systems of other countries from the representative sample of these initiatives (European Commission, 2007). The main focus is on inquiry-based science education – IBSE, which, according to what we know so far, proved its effectivity in both primary and secondary education – not only did the pupils' interest increase, but so did their results, and so was improved the teachers' motivation (Sherwood, 2007). IBSE was found effective for all groups of pupils, from the least to the most capable, according to their effort to be the best. In addition, IBSE turned out to be beneficial for support of girls' interest in scientific activities. The fact that IBSE and the traditional pedagogical approaches are not contrary and can (and should be) mixed in the science education in order to adjust the teaching to pupils' various ways of thinking and age preferences is also important (European Commission, 2007). These reasons became the starting point for solving this problematics at the Faculty of Science and Faculty of Mathematics and Physics at the Charles University. This was done in a structured way, in the frame of both national and European project.

METHODS

The main goal of the projects is to increase the interest in and the effectivity of the science education at primary and secondary schools with the help of interesting contents, current themes emphasizing their practical applicability and new activizing educational methods, especially IBSE.

The starting point of the project solving was the analysis of strategical and curricular documents of CR and EU (Čtrnáctová et al., 2007), the results and recommendations of the international projects TIMSS and PISA, of the projects Pollen (http://www.pollen-europa.net/) and Sinus-Transfer (http://sinus-transfer.uni-bayreuth.de/), and the results of national projects solved in 2005-08 with the support of ESF (Čtrnáctová et al., 2007; Řezníčková, 2009; Straková et al., 2006). At the same time we have performed a questionnaire survey to find out the current state of science education and the needs of their teachers at the primary and secondary schools in the Czech Republic.

The results of the analysis of said documents and the questionnaire survey were the theoretical starting points for the further project activities in the lines of various scientific subjects. These activities aim to improve the teaching quality by innovation and actualization of the educational programmes as well as the methods of teaching based on pupils' practical activities and a problem approach with their realizations in specific school conditions. The emphasis is put on the development of key and field competences, on the development of the higher-order intelectual skills of the pupils, especially the critical thinking, creativity and self-reflection. Thanks to the methods that use active approach of pupils, other key competences are also developer. The project activities are resting on creating, verifying and realizing the thematically aimed modules from the subjects of biology, chemistry, physics and geography at the primary and secondary schools.

RESULTS

The chosen methods were gradually applied to selected themes in solved national projects simultaneously with the creation of specific educational materials for various educational fields and cross-section themis, in total, 40 educational materials were created. Gradually, 82 primary and secondary schools, 168 science teachers and 3,482 pupils joined the project. The educational materials were continuously being made available to the science teachers who gradually verified them in the school practice and evaluated them. The evaluation tools were mainly questionnaire surveys, as well as tests and directed interviews. All the teachers evaluated them very positively – they especially prized their immediate benefit for their own pedagogical work and for the improvement of the quality of science education at primary and secondary schools.

During further solving of this problematics, further study and methodical materials will be created for each modul, based on IBSE, and selected teachers will be trained to realize them. As part of project solving there will be 10 months of lessons based on the created and pilot-verified modules at selected primary and secondary schools. Its effectivity will be evaluated at the final stage of the project.

CONCLUSIONS

Although the inquiry-based science education is generally acknowledged and recommended because of its clear advantages, the results from the real world show that it's still relatively underused in the school lessons. However, it's not just because of the greater time demands, but also, and probably more often, in the lack of availability of the resources, specific themes and problems. Another important cause of the low level of inquiry-based education usage is the conviction of certain teachers that the traditional way of education gives the necessary knowledge to the students much more effectively.

This is why further research has to focus on the experimental checking of teaching effectivity of inquiry-based education, both in short-term and long-term, especially long-term. The existing research was so far mostly theoretical, the specific, experimentally verified research is rare and in biology and chemistry it's practically nonexistent. We think that this is the direction our research has to take in the future. The specific possibility of its realization is currently available due to the ESTABLISH project that started in 2010 which we are solving together with other coworkers from 14 institutions in 11 European countries.

ABSTRACT

We analyze the conceptions of 4248 teachers on Environment and GMO (Genetically Modified Organisms), in 12 European countries: Cyprus, Estonia, Finland, France, Germany, Hungary, Italy, Lithuania, Malta, Poland, Portugal, Romania.

Most of the differences between teachers' conceptions are observed inside each country. Some of them (related to preservation or utilization of Environment) significantly differentiate the 12 countries. Biology teachers have more knowledge on GMO and more opinions pro-GMO than their colleagues. Female teachers are significantly more anti-GMO than their male

colleagues. More a teacher studied at University, more he or she thinks that the resources of our planet are limited.
