CLIMATE SCIENCE LITERACY

Lučka Kajfež Bogataj

University of Ljubljana, Slovenia

Abstract

Our common future is at risk from global change, especially climate change. There is a perceived need to foster awareness about climate change in schools and universities and to engage young people and future professionals in the search for local solutions for a problem with has global dimensions. Climate change will bring economic and environmental challenges as well as opportunities, and citizens who have an understanding of climate science will be better prepared to respond to both. To protect ecosystems and to build sustainable communities that are resilient to climate change a climate-literate citizenry is essential. Climate Science Literacy is an understanding of individual's influence on climate and climate's influence on individual level and society. A climate-literate person understands the essential principles of Earth's climate system, knows how to assess scientifically credible information about climate, communicates about climate and climate change in a meaningful way, and is able to make informed and responsible decisions with regard to actions that may affect climate. This paper suggests that education responses are needed which attend to provision of both appropriate educational infrastructure and relevant knowledge and skills.

Keywords: climate change, education, knowledge

1. Introduction

Climate Change is one of the most pressing global issues of our time. Human activities increasingly influence the Earth's climate (IPCC, 2007) and ecosystems (MEA, 2005). The impacts of climate change are already being observed and are projected to become more pronounced. Over the past 150 years, mean temperature has increased by 0.8 ºC globally and by about 1 ºC in Europe. Ten last years (2000–2009) were the 10 warmest years in the instrumental record of global surface temperature (since 1850). Without global action to limit emissions, the IPCC (2007) expects that global temperatures may increase further by 1.8 to 4.0 ºC by 2100. This means that temperature increase since pre-industrial times would exceed 2 °C. Beyond this threshold irreversible and possibly catastrophic changes become far more likely. To halt climate change, global greenhouse gas emissions must be reduced significantly, and policies are put in place to do so. The main sources of man-made greenhouse gases are: burning of fossil fuels in electricity generation, transport, industry and households; agriculture and land use changes like deforestation; land filling of waste; and use of industrial fluorinated gases. Bit unfortunately, even if policies and efforts to reduce emissions are effective, some climate change is inevitable. We must therefore also develop strategies to adapt to the impacts of climate change in Europe and especially beyond, since the least developed countries are among the most vulnerable, having the least financial and technical capacity to adapt. It becomes obvious that besides communication and awareness raising programs, specific educational approaches and training programs are needed to develop and promote knowledge and competencies in the field of climate change (AAAS, 2007).

2. Teaching climate change

For addressing the complex multi-stakeholder and multilevel challenges associated with climate change mitigation and adaptation an appropriate knowledge base is needed not only among public authorities and academia but also among civil society, business sector etc. in order to have problem aware constituencies in the countries of the world supporting with their attitudes and actions governments towards bold future oriented global climate change action (Burandt and Barth, 2010).

Climate and changes in climate have influenced in the past and will continue to influence what kinds of life forms are able to exist. Yet climate change is a phenomenon with which we humans have little experience, at least in historic times, and teaching about it presents special challenges to educators. Working with a complex topic like climate change is challenging both for students and teachers. Understanding the basic principles that contribute to maintaining and causing changes in weather and climate increases our ability to forecast and moderate the effects of weather and to make informed decisions about human activities that may contribute to climate change.

Climate science, like any other scientific discipline, develops through vigorous debates between experts, but there is an overwhelming consensus regarding its fundamentals. Climate science has a firm basis in physics and is supported by a wealth of evidence from real world observations. But climate change is not just an environmental problem. It is an economic problem, a political problem, an international security problem (Table 1). In a warmer world, accessibility to food, water, raw materials, and energy are likely to change. Human health, biodiversity, economic stability, and national security are also expected to be affected by climate change. Climate model projections suggest that negative effects of climate change will significantly outweigh positive ones.

Table 1. Possible impacts of climate change due to changes in extreme weather and climate events, based on projections to the mid to late 21st century (Modified after IPCC, 2007).

Phenomena and direction of trend	**Likelihood of future trend**	**Major projected impacts by sector**			
		Agriculture, forestry	**Water resources**	**Human health**	**Industry/settlement/ Society**
Fewer cold days and nights; more frequent hot days and nights over most land areas.	Virtually certain	Increased yields in colder environments; decreased yields in warmer environments	Effects on water resources relying on snow melt; increased evapotranspiration rates	Reduced human mortality from decreased cold exposure	Reduced energy demand for heating; increased demand for cooling; declining air quality in cities; effects on winter tourism
Warm spells/heat waves: frequency	Very likely	Reduced yields in warmer regions due to heat stress; fire	Increased water demand; water quality problems,	Increased risk of heat-related mortality,	Reduction in quality of life for people in warm areas without air conditioning; impacts on

increases over most land areas		danger increase	e.g., algal blooms	especially for the elderly, chronically sick, very young and socially-isolated	elderly, very young and poor; reduced thermoelectric power production efficiency; disruption to commerce
Heavy precipitation events: frequency increases over most areas	Very likely	Damage to crops; soil erosion, inability to cultivate land due to water logging of soils	Adverse effects on quality of surface and groundwater; contamination of water supply; water scarcity may be relieved	Increased risk of deaths, injuries, infectious, respiratory and skin diseases, post traumatic stress disorders	Disruption of settlements, commerce, transport and societies due to flooding; pressures on urban and rural infrastructures
Area affected by drought: increases	Likely	Land degradation, lower yields/crop damage and failure; increased livestock deaths; increased risk of wildfire	More widespread water stress	Increased risk of food and water shortage; increased risk of malnutrition; increased risk of water- and food-borne diseases	Water shortages for settlements, industry and societies; reduced hydropower generation potentials; potentials for population migration
Sea leverlrise	Likely	Salinisation of irrigation and well water	Decreased freshwater availability due to saltwater intrusion	Increased risk of deaths and injuries by drowning in floods; migration-related health effects	Costs of coastal protection, land-use relocation; Displacement of human populations, abandonment of settlements, relocation of infrastructure

Despite growing scientific evidence that global warming will have serious impacts worldwide (Richardson, 2009), lately public opinion is moving in the opposite direction. Over the past year many countries have experienced rising unemployment, public frustration with financial crisis, largely pushing climate change out of the news. Meanwhile, a set of emails stolen from climate scientists and used by critics to allege scientific misconduct may have contributed to an erosion of public trust in climate science. It is also clear that public understanding of climate change fundamentals - that it is happening, is human caused, and will have serious consequences for human societies and natural ecosystems around the world - is heading in the wrong direction. Students of all ages (including college students and adults) still have difficulty understanding what causes climate change. These findings underscore the critical need for more and improved climate change education and communication (Bangay and Blum, 2010).

Climate change science is complex and can certainly be confusing (Figure 1). It is highly interdisciplinary, cutting across numerous disciplines. Many if not most science educators teaching traditional biology, chemistry and physics may never have been trained in the basics of climate science. Earth sciences have also been traditionally rooted in geology, where rocks rule and deep time prevails. Climate fits between geological and meteorological processes, and all too often falls through the disciplinary cracks. There are many well-written and authoritative books for a general audience that can help educators and others understand the science of climate change and its environmental and societal impacts. Also there is an abundance of information and materials available online for science educators and communicators, like official site of the Intergovernmental Panel on Climate Change from which all of the IPCC reports are available for download. Some excellent Web sites, which provide access to a variety of authoritative resources from government, academic, and scientific organizations are given in Table 2.

Most students learn the basics of weather at a young age. It’s a good place to start—observing local weather events and seasonal changes. But climate, while obviously related to weather is inherently different, requiring different theories, models and pedagogy. In many countries, few teachers have training—or the time or mandate—to dig deeply into climate processes. When climate change is taught, it is often ad hoc, emphasizing polar bears and carbon calculators over in-depth understanding of carbon, climate and complex interactions. This is a pity, because interest in climate change issues provides a great opportunity to talk about basic science, as well. Furthermore climate change science is one of the first science topics where a social science physical science collaboration is required.

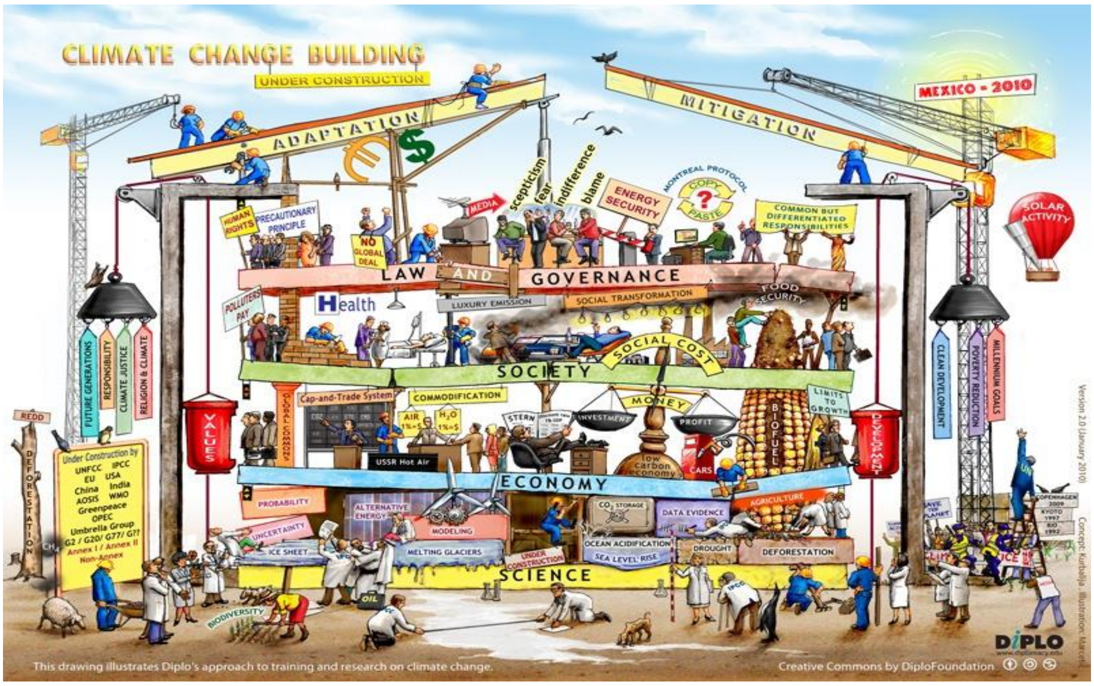

Figure 1: Climate change science is complex and can certainly be confusing (http://www.diplomacy.edu/climate/)

However, for the young people in our communities and classrooms who are learning about the planet, acquiring skills and insights into the complex socio-environmental and economic realities of the world, knowing the basics of climate science is imperative. Scientific information on climate change must be disseminated in a way that allow is to be broadly understood, including elements related to its environmental, social, economic and policy aspects to schools and universities around all continents. Students should have a chance to discuss the problems, barriers, challenges and chances and potentials related to climate change both in the local and regional level but also globally. This will raise awareness among secondary and university students on the complexity of matters related to climate change and the need for personal engagement and action.

Human-induced global change is really a symptom of outdated ways of thinking, worldviews, and ideologies that are not only unsustainable but threaten the very survivability of the human species and environmental systems we depend on. For centuries, people thought that earth processes were so large and powerful that nothing we could do would change them. This was a basic tenet of geological science: that human chronologies were insignificant compared with the vastness of geological time; that human activities were insignificant compared with the force of geological processes. And once they were, but no more. There are now so many of us cutting down so many trees and burning so many billions of tons of fossil fuels that we have indeed become geological agents. We have changed the chemistry of our atmosphere, causing sea level to rise, ice to melt, and climate to change. There is no reason to think otherwise. Discovering ways to encourage whole systems, holistic thinking and behaviour is perhaps the ultimate conundrum of this generation as we move to address the phenomenal challenges of the 21st century.

How to better teach students about climate change has been an issue of great concern among climatologists and also educators. In recent years educators' awareness of climate change has continuously improved. However, majority of countries haven't yet set up a systematic educational program on climate change. The topic is indeed complex because the Earth's systems are complex, and scientists themselves are not at all certain of the potential ramifications of our interference with these systems. Formidable from an educator's point of view is the intangibility of climate change: its global scale and seemingly slow progression make it a phenomenon that does not easily lend itself to classroom demonstration. And teachers and students who wish to take action on climate change find themselves up against the ingrained habits and attitudes of an industrial society created and powered by fossil fuels and supported by political inertia in establishing regulatory policies to curb greenhouse gas emissions.

It must be understood that climate science literacy is an ongoing process. Students are not expected to understand every detail about all of the fundamental climate science. Full comprehension of these interconnected concepts will require a systems-thinking approach, meaning the ability to understand complex interconnections among all of the components of the climate system. Moreover, as climate science progresses and as efforts to educate the people about climate's influence on them and their influence on the climate system mature, public understanding will continue to grow.

But teaching about and taking action on climate change may not be as difficult as it seems. Teachers and students should explore some of the key questions related to climate change: What are its causes? What might we expect? What are governments doing about it? And, most important, what can schools and students do about it? In working with young people, teachers have a great many opportunities to address these vitally important questions. Many topics that would be part of a study of climate change are already part of most primary school curricula: these include, for example, technology topics such as energy systems; social studies topics such as political decision-making; or geography and science topics such as weather systems, photosynthesis and decomposition, and adaptations of plants and animals to specific habitats and climatic conditions. Moreover, many teachers and students are already engaged in activities that are helping to reduce their own and their schools' greenhouse gas emissions: planting trees near the school building, conserving energy and water, reducing waste, walking or cycling to school instead of driving. It is only a small step to incorporate discussion of climate change into these curricular areas and activities. Promoting climate literacy through informal science learning environments is important, as well.

Regarding climate change society has three options. First is mitigation, which means measures to reduce the pace & magnitude of the changes in global climate being caused by human activities. Examples of mitigation include reducing emissions of GHG, enhancing “sinks” for these gases, and “geoengineering” to counteract the warming effects of GHG. Second choice is adaptation, which means measures to reduce the adverse impacts on human well-being resulting from the changes in climate that do occur. Examples of adaptation include changing agricultural practices, strengthening defense against climate-related disease, and building more dams and dikes. Suffering the adverse impacts that are not avoided by either mitigation or adaptation is the third option. Mitigation and adaptation are both essential. Human-caused climate change is already occurring and is already dangerous. Adaptation efforts are already taking place and must be expanded. But adaptation becomes costlier and less effective as the magnitude of climate changes grows. The greater the amount of mitigation that can be achieved at affordable cost, the smaller the burdens placed on adaptation and the smaller the suffering.

3. Conclusions

Climate change is not just our grandchildren’s problem or our children’s problem. It is our problem. We and our predecessors caused it. We have the responsibility to address it. If not addressed with adequate wit, wisdom, and resources, the disruption of global climate will thwart societal aspirations everywhere. It will erode well-being where it now exists and it will prevent the attainment of well-being everywhere else. It will undermine any prospect for international peace and stability. The costs of addressing it will be far less than the costs of ignoring it. The countries and companies that take the lead in turning challenge to opportunity & cost to benefit will help themselves and help us all.

Education is a critical element in the response to the challenges of climate change. Climate is an ideal interdisciplinary theme for lifelong learning about the scientific process and the ways in which humans affect and are affected by the Earth’s systems. This rich topic can be approached at many levels, from comparing the daily weather with long-term records to exploring abstract representations of climate in computer models to examining how climate change impacts human and ecosystem health. Learners of all ages can use data from a range of physical, chemical, biological, geographical, social, economic, and historical sources to explore the impacts of climate and potential adaptation and mitigation strategies.

Learning about climate change not only provides relevant literacy but it also allows empowering, enabling, motivating, informing, and educating the public around the technical, political, and social dimensions of climate change. In addition, unlike literacy which has a uni-directional connotation, engagement is as much about informing the public as it is about also informing experts and decision-makers. Communication should be viewed as a two-way process - with frames providing the context for dialogue - where experts and decision-makers seek input and learn from the public about preferences, needs, insights, and ideas relative to climate change solutions and policy options.

DEVELOPING SOCIO-CULTURAL AND HUMAN VALUES IN SCIENCE AND TECHNOLOGY THROUGH SOCIOSCIENTIFIC ISSUES

Dana L. Zeidler

University of South Florida – Tampa, USA

Zeidler@usf.edu

The overarching mission of IOSTE is to encourage the peaceful and ethical use of science and technology in the service of humankind – it explicitly opposes the use of science and technology by government or other

organizations for military purposes against civilians. Key objectives that align with its mission include fostering dialogue that: 1) Highlight S&T education for citizenship and for informed, critical, and active participation in democracy; 2) Emphasize the cultural and human values of S&T; 3) Advance S&T education for a just and sustainable development; 4) Encourage the peaceful and ethical use of S&T in the service of humankind; and 5) and consider how S&T education can contribute to the fight against poverty, discrimination and injustice (http://www.ioste.org/). The purpose of this presentation is to argue the case that the use of socioscientific issues is not only consistent with the development of socio-cultural and human values in science and technology, but is necessary to fulfill the mission of IOSTE as well as the über goal of science education – achieving scientific literacy.

The basic premise driving our research on the development and implementation of socioscientific issues (SSI) is fairly straightforward; that contextualized argumentation in science education may be understood as an instance of education for citizenship. If one accepts this premise, then it becomes essential to present to students the humanistic face of scientific decisions that entail moral and ethical issues, arguments and the evidence used to arrive at those decisions. Separating learning of the content of science from consideration of its application and its implications (i.e. context) is an artificial divorce (Aikenhead, 2006; Zeidler, Sadler, Applebaum & Callahan, 2009). The SSI movement focuses specifically on empowering students to consider how science-based issues and the decisions made concerning them reflect, in part, the moral principles and qualities of virtue that encompass their own lives, as well as the physical and social world around them.

In his extensive review of literature regarding scientific literacy (SL), Roberts (2007) provides an important distinction between two generalized views of SL: Vision I emphasizes aspects of academic content related and aligned to the goals of science, while Vision II emphasizes an approach that is broader in scope, involving personal decision-making about contextually-embedded science and social issues. It is within Vision II that socioscientific issues are embedded, although our investigations contain features of SSI reasoning that arguably surpass Vision II. The "heuristic device" (p. 775) employed by Roberts works well to contrast the field's perceptions often associated with the construct. Because we realize that it is necessary to parse out components of a construct (such as SL) in order to clarify its constituent parts, we acknowledge that any alternative heuristic we might invoke would undoubtedly frame the issue in a different orientation. Hence, our corresponding argument can best be located in a more comprehensive, and necessarily more inclusive stance of Vision II. In other publications, we have argued (Sadler & Zeidler, 2005; Zeidler, 1984; Zeidler & Keefer, 2003; Zeidler & Sadler, 2008a; 2008b; Zeidler, Sadler, Simmons & Howes, 2005) that any conceptualization of the intention and significance of scientific literacy falls short of the mark, if moral reasoning, ethical considerations and character development are not part of our understanding of SL.

The Socioscientific Issues framework seeks to involve students in decision making regarding current social issues with moral or ethical implications embedded in scientific contexts (Sadler, 2004; Zeidler & Keefer, 2003; Zeidler et al., 2005). These issues provide students with opportunities for active reflection upon an issue and examining how the issue relates to their own lives, as well as the quality of life in their community (Driver, Leach, Millar, & Scott, 1996). It is equally plausible that certain ethical issues can become the context of embedded scientific content and certain Nature of Science (NOS) tenets (Abd-El-Khalick, 2003; Sadler, Chambers & Zeidler, 2004; Zeidler, Sadler, Applebaum & Callahan, 2009; Zeidler, Walker, Ackett & Simmons, 2002). Hence, our central argument is that SSI can provide an epistemological context for students' conceptual understanding of important scientific and social matters, thereby serving as a venue for the development of character and reflective judgment. In doing so, a more inclusive stance of Vision II SL becomes necessary.

We have, therefore, suggested that the vision of SL we wish to advance is more aligned with Vision II, but pushes the envelope a good deal further along Robert's original continuum. The rationale behind our use of the term *functional* scientific literacy is one that would be sensitive to both dominant and alternative normative views of SL. To the extent that the emphasis on moral growth, reflective reasoning and the formation of character is part and parcel of a radically different notion of SL (fundamentally different from Vision 1 and distinctly different from Vision II), functional SL in the sense that we advocate, is contextually and culturally sensitive to the needs of the learner. This perspective is consistent with the sociocultural perspective of SL that Sadler (2009) advances; it prioritizes enculturation and practice. Within this view of SL, the activity of science as practiced in any culture is legitimized, and students have access to the norms of that culture wherever it may be found. Kelly (2007) is certainly sensitive to this view inasmuch as he recognizes the selection of goals for scientific literacy with particular outcomes of citizenship. Given the pluralistic nature of societies, he questions whether a focus on "building public reason" with its emphasis on critical discourse should trump a focus on selecting a priori outcomes of what students should know about science. Under our functional view of SL, a priority is given to investigating how SSI may develop both SL and character through experiences that maximize opportunities for citizenship (Berkowitz, 1997; Benninga, Berkowitz, Kuehn & Smith, 2003; Berkowitz, Battistich & Bier, 2008).

One aspect of our research has examined how elements of students' argumentation including related aspects of fallacious errors in judgment play out in resolving what are essentially moral claims embedded in SSI (Walker & Zeidler, 2007; Zeidler, 1997; Zeidler, Lederman, & Taylor; 1992; Zeidler, Osborne, Erduran, Simon, & Monk, 2003). A second aspect of our research has focused on how variations in subject matter knowledge (i.e. science content knowledge) across different grade levels affect students' reasoning on SSI (Dolan, Nichols & Zeidler, 2009; Greely, Lodge & Zeidler, 2009; Sadler & Donnelly, 2006; Sadler & Fowler, 2006; Sadler & Zeidler, 2004; Sadler & Zeidler, 2005b; Zeidler, Walker, Ackett & Simmons, 2002). A third venue of research has attempted to shore-up and clarify aspects of theoretical and conceptual frameworks connected with SSI (Fowler, Zeidler & Sadler, 2009; Sadler, 2004a; Sadler, 2004b; Sadler, Barab, & Scott, 2007; Sadler, Chambers & Zeidler, 2004; Sadler & Zeidler, 2005a; Zeidler, 1985; Zeidler & Keefer, 2003; Zeidler & Nichols, 2009; Zeidler & Schafer, 1984; Zeidler, Walker, Ackett & Simmons, 2002). Central to all these studies is the importance placed squarely on understanding how students reason and react reflexively to variant evidence and beliefs. In doing so, we provide opportunities for students to negotiate and argue with others and ultimately reflect as they form judgments about controversial issues.

In doing so, we are able to begin a journey of prudent steps that lead to the formation of conscience. The education of a public is essentially a normative process and a moral task insofar as decisions about desirable ends are inextricably linked to pedagogical means. It is one thing to ask, as in moral philosophy, what is the nature of the good? It is quite another to ask, how does one get that way? The latter question falls in the domain of moral education (Green, 1999). To the extent that we, as educators, are concerned about guiding our students to question what is right, proper, and necessary, then we *also* need to provide the conditions necessary to develop character. To suggest that a central tenet of science education is the cultivation of scientifically literate citizens is to establish, a priori, a set of implicit norms about our roles as educators in fostering the formation of an "informed" public and subsequently the establishment of a collective social conscience. It is important to note that this process of normation does not prescribe rules of behavior (i.e. how one ought to behave); rather the process encourages individuals to *think about* what they ought to do. The difference is not merely semantic. While the former interpretation compels people to be compliant and obedient, the latter view is aimed at developing the formation of conscience through the exercise of reflexive judgment. Reflexive judgment, understood in this context, is primarily concerned with self-evaluation. Did I do that well? How poorly did I perform? Could I have done that better? While such questions are not ordinarily thought of as *moral* matters, they are concerned with a type of self-evaluation not unlike Flavell's (1987) use of "metacognition" or Dewey's (1910) notion of "reflective judgment." We can think of this as thinking turned back on itself relative to one's own gauge of virtue. Since virtue may be equated with excellence (note Book Two of Aristotle's *Nichomachean Ethics*, 1998), one can argue that a virtuous life is one filled with deeds par excellence. The desire to consistently hold one's actions up for internal scrutiny is a fundamental feature of conscience.

The cultivation and development of self-evaluation understood in this manner is a feature of SSI. The SSI movement focuses specifically on empowering students to consider how science-based issues and the decisions made concerning them reflect, in part, the moral principles and qualities of virtue that encompass their own lives, as well as the physical and social world around them. If we want students to think for themselves, then they need opportunities to engage in informal reasoning, discourse, argumentation, and practice utilizing evidence-based reasoning within their science classes. Accordingly, we must present topics that challenge students' normative expectations and that compel them to engage one another in the resolution of differences existing among individuals via argumentation and discourse during face-to face interactions. Such reasoning deals with what Rest, Narvaez, Bebeau and Thoma (1999) term issues of "micromorality." Moral reasoning, then, may arise out of discourse and argument. It is, on the one hand, a type of technical competence whereby students can evaluate potential decisions with respect to how well those decisions attend to potential short and long-term future consequences. But on the other hand, it extends beyond mere technical competence insofar as the student must consider how well their decisions attend to past historic inequities; such decisions may then be said to be just, fair and equitable. Such reasoning, then, truly arises out of a special type of reflexive judgment that transcends technical competence in decision-making, because it adds to the formation of conscience and empathy, surely necessary in the larger picture of moral education, norm acquisition and character formation. It would be prudent for science educators to understand that the future and quality of life within our social institutions is indelibly linked to the quality of educative experiences we provide for our children.

THE SCIENCE CURRICULUM: A contest of values, purposes, interests and possibilities

Peter J Fensham

QUT and Monash University

The theme of my lecture is *THE SCIENCE CURRICULUM AS A CONTEST,* and in it I will share examples of *how that contest has been played out historically, what the contests are today, who are the contestants,* and *what is at stake.*

That the science curriculum is a contest should not be surprising, because the word "CURRICULUM" is derived from a Latin word that in Roman times was associated with the "race course". It referred both to the running of the race and to the nature of the race. CURRICULUM was also used in a life sense to refer to the series of deeds and experiences through which Roman children grow to become adults.

Each of these meanings is reflected in how the word is used in formal school education and in science education in particular. Formal education for young people takes a very large proportion of a country's national budget, so it is no surprise that the curriculum for that education is contested. Furthermore, the link between science and technology and the economy and political status of countries is now so strong that the contest for the science curriculum is particularly intense.

Sometimes "curriculum", refers to a statement of the intended knowledge, skills and attitudes for learning and to the pedagogies that are employed by teachers to facilitate the learning. In this lecture I am more concerned with the "racecourse" sense of the Science curriculum – its intended content.

David Layton (1973) introduced me to the idea of the science curriculum as a contest in his seminal book **Science for the People**. In the 1840s a village school master in England gained the interest of a senior inspector of schools for his introduction of basic science for his pupils, destined for agricultural labouring. This seemingly sensible innovation was quickly opposed by an array of powerful voices. The inclusion of science more widely in schooling was defeated.

It was not right to equip the working classes with knowledge at that time unavailable in the schooling of the upper classes. Science was not morally uplifting, compared with the humanities. The scientific community disagreed about which aspects of science were most appropriate. Geology, important for understanding soils but also for the expansion of the railways and mining, could lead to unhelpful religious antagonism, a foresight of what would arise over natural selection a few years later.

This early contest over the curriculum for science featured two issues- *science as useful knowledge* and *science as moral knowledge*.

These issues about the role of the science curriculum are still contested today, albeit with changing definitions, changing political contexts, and new sets of contestants.

Science as useful knowledge

The teaching of the sciences in schooling emerged again towards the end of the 19th C and now less contentiously, because their role was to facilitate the transition of the tiny percentage of students who would go on to university science studies. The curriculum of these sciences now had the simple purpose of being preparatory. Contestants in this period were academic scientists and usually well educated science teachers, and their contest was:

> *What is the basic knowledge in the sciences as preparation for science-bound students?*

This single preparatory purpose was still evident in the major efforts in the 1960s to bring the school science curriculum up-to-date (in line with university sciences) after its neglect due to the 1930s economic depression, World War 2 and its aftermath. The priority of this curriculum development was still the reformulation of the sciences for the academically selected, science-bound students. The contestants were older science teachers and the interested academic scientists. The issue was:

> *How can the now conceptual basis of the sciences be included in what were essentially descriptive science curricula?*

This conceptual basis, backed by powerful scientific and political forces (the post Sputnik era), won at the expense of more interesting descriptive science, its applications, and the historical dimension, the main means for teaching the nature of science. Nevertheless, this era of curriculum later first recognised the need for school courses in science or the sciences for students more generally, and an array of interesting materials to support such alternative science curricula were produced.

By the 1980s, more and more students were staying for longer in secondary education, and a series of national reports with the generic theme of *Science for All* were produced (Fensham, 1988). Serious concerns about the inadequacy of the "academically-oriented science" were raised by science educators, a newly emerging group of academics. Opposing them were academic research scientists and elite science teachers. On each side, there were other influential but vacillating stake holders from the society itself. The issue for this curriculum contest was:

> *How can the school science curriculum meet the needs of the science-bound minority and of all students in an increasingly, S&T influenced society?*

For almost thirty years, we in the science and technology education communities, have lived with this contest. IOSTE, initiated in Canada in 1979 has been a major forum for debating this contest, so it is interesting that the report, **Science for All Canadians**, uniquely added two other societal demands on school science – *the world of work* and *moral education.* (Science Council of Canada, 1984).

Suggestions for resolution

Douglas Roberts (1982) found at least seven different purposes for school science in the reforms of the 1960/70s. He pointed out that if we try to teach for all these purposes at the same time, some will be inevitably be lost, and the established one of providing preparatory, foundational knowledge is likely to win. Why not, he argued, see the years of schooling as made up of stages in which science teaching sets out to achieve just one or two of these purposes (the *curriculum emphasis)* that relate especially to the learners' needs at that stage.

A number of countries have explored, with varying degrees of success, this idea of '*curriculum emphasis'* as a compromise solution to the contest. At the senior levels of schooling many countries have developed different science curricula for the same level of schooling. These efforts to provide a better science curriculum for the citizen-bound needs of students inevitably fail if educational status remains with the specialised science disciplines. Thailand, in the 1980s employed an unusual solution to the contest with great success, and now 21st Century Science in England and Wales has offered an attractive solution to the curriculum contest in the senior years.

Following the *Science for All* reports, various reformers sought to resolve the contest by developing innovations for school science under the banner of Science/Technology/Society (STS)(Solomon and Aikenhead, 1994). The more cautious reformers simply added examples of societal applications of science (technologies) as optional extras to the existing science content. The more radical allowed these examples of technologies and society to have a more determining influence on the Science to be taught. This promising resolution was quickly lost when Technology was established as a new subject for mainstream schooling, with its timely subsumption of computer-based elements. Without Technology, Science's bridge to Society was lost, and the proponents of preparatory conceptual science won again, and now their view stretched through all the years of schooling.

After a decade the negative consequences of this curriculum on the interest of students in science and science careers have become increasingly evident, re-opening the contest.

One suggestion has called for a curriculum, that gives more attention to the 'stories of science' and engages learners more discursively. Another is described as context-based science and Roberts (2007) elaborated the contest in terms of two visions for scientific literacy. Vision I looks inward to Science itself and leads to the academic, preparatory science curriculum. Vision II looks outward to situations in society involving science and technology and for allows these to become determining for the school science curriculum.

International comparisons of science achievement are now influencing the contest, with the IEA's TIMSS project reinforcing the curriculum of Vision I, whereas the OECD's PISA Science is more identified with a Vision II of science learning.

Since 2000, the contest over the science curriculum as useful knowledge has become more confusing as powerful advocates from the world of work and from the Knowledge Society call for generic competencies in learners. The science curriculum's reliance on the acquisition of established knowledge makes it vulnerable to such new contestants (Gilbert, 2005).

Science education as a Contest about moral knowledge

Lee Shulman, in devoting his 1987 Presidential address to the American Education Research Associatiion to teachers' "pedagogical content knowledge" (PCK), unknowingly built a bridge across an educational chasm. This chasm divides educational traditions about curriculum that have emphasised very different views of the curriculum "racecourse". One sees schooling in terms of *an induction into subjects* and the other sees schooling as *life and character formation – a sense of education that the* German words, Bildung and Didaktik, very much embody.

In one tradition the curriculum of content knowledge for a discipline is determined by the educational system , at a level beyond the school and individual teacher. The teachers' responsibility is simply to teach this given content. In the other tradition it is the teacher's responsibility to select from the disciplinary knowledge both what should be taught and its teaching. This fundamental difference can be seen in five principles that are well known in the Didaktik tradition of teaching disciplinary fields like the sciences (Klafki, 1995). Principles 1&2 are guides to choosing the science content so that it will enhance the learner's formation. Principles 3,4,&5 are about the subsequent teaching. Where the first tradition is strong, science teacher education begins with the latter three principles and ignores the first pair entirely.

In one tradition the content for teaching is very much identified with the content and logic of the discipline itself. In the latter, the disciplinary knowledge is recognised as not automatically what is best for the educational purpose of schooling, and needs to be "selected and translated'. Two curriculum documents published in 1994 epitomised the chasm. One set out the curriculum of school education like the decathlon events in the Olympic Games – a "racecourse" consisting of learning a number of different knowledge subjects. The other, as a **Core Curriculum** for education in Norway, follows the life sense or "moral" sense of CURRICULUM as a series of events leading to visionary goals of a rounded and moral person.

These two traditions should not simply associated with particular national systems of education, but they do, in different systems differentially influence how the curriculum contest in a given country is played out. Asian countries, commonly refer to the place of values in the curriculum. Western countries tend to associate student interest in a subject with its teaching and not as a determinant of the curriculum's content. Roberts' Vision II for scientific literacy and the PISA Science test are now being criticised because they overestimate the science component of real world S&T situations. Zeidler and Sadler have pointed out that these socio-scientific situations (SSI) often involve other components including ethical ones that need to be recognised the teaching of their science. Yet another new aspect of the curriculum contest about science as moral knowledge derives from the Big Challenges facing science and technology. This new aspect is the uncertain nature of the science involved. The frustration of so many over the global warming issue at Copenhagen is directly related to the failure of our science curricula to include "risk", uncertainty, and the precautionary principle. Resolving this contest may be our greatest challenge as science and technology educators.

”THE SECOND SEX” IN SCIENCE WHY ARE WOMEN STILL UNDER-REPRESENTED IN SCIENCE AND TECHNOLOGY, WHY DOES IT MATTER, AND WHAT CAN WE DO ABOUT IT?

Ellen Karoline Henriksen

Department of Physics, University of Oslo

ABSTRACT

In this paper, Beauvoir's (1949) description of women as "the second sex" is used as a starting point for exploring the reasons for, and possible ways of handling, the under-representation of women in science, tchnology, engineering and mathematics (STEM). A brief description of the situation is given, and four reasons are proposed why it is important to seek a greater gender balance in the STEM fields. Building on research regarding young people's (girls' in particular) relationship and attitudes to science, the expectancy-value model of educational choice (Eccles & Wigfield, 2002) is used as a framework for exploring the reasons why many women (and men) opt away from science. Based on the findings presented, the paper goes on to point out possible ways forward in order to increase the diversity of personalities that may feel attracted to science and technology so that the future workforce within these fields will not only be greater in numbers and more even in gender distribution, but will generally include a greater multitude and variety of outlooks, experiences and aims.

Keywords: *Gender, science, technology, educational choice*

INTRODUCTION: WOMEN AS "THE SECOND SEX" IN SCIENCE?

In 1911, Marie Sklodowska Curie became the first person to have earned two Nobel prizes – for her investigation of radioactivity and discovery of new radioactive elements. Curie is arguably the most well-known female scientist in history, and her story still holds fascination, not least because of her struggle to make a proper place for herself within the scientific community. She is seen on photos from physics conferences at the time, usually the only woman. In a Norwegian science textbook for 16-year-olds, the reader gets to know how Curie was working: often in the kitchen, with the result that her cookbook is still so radioactive that it has to be displayed behind thick glass in a museum.

In 1949, Simone de Beauvoir wrote the groundbreaking book "The second sex" (Beauvoir, 1949), thereby laying the premises for a discussion of what it means to be a woman and how the feminine is construed not as an experience or a mode of being in and of itself, but rather as being something different from a man. She describes how the man defines what a human being is and should properly be – or, transferred to our present context, what a *scientist* should be. The man is seen as *transcending* his boundaries, developing, expanding his knowledge and challenging his abilities, shaping nature and culture. Woman, on the contrary, has been seen (says Beauvoir) as *immanent*, that is: stagnant, non-transgressive, with no drive to challenge and develop her abilities to the fullest (see for instance Pilardi (1999))– and, in our context, with no proper place in science but as an exception. Beauvoir goes on to show how this is connected with the situation of women in society, where they are subordinate to men, and to argue that women can strive towards greater freedom and participation.

Today, 60 years after "The Second Sex", economic and societal conditions have changed and at least in Western countries, some of the constraints described by Beauvoir would seem to have been removed or at least greatly reduced. However, women continue to be "the second sex" in science: The male researcher is still the norm and the "female mathematician", for instance, is very often presented as exactly that: An oddity, a phenomenon calling for attention. Young girls and women continue to make educational and career choices that resemble those of their grandmothers – although today's young women give different *reasons* for their choices.

Thousands of pages have been written about women in science, and had there been a simple explanation and an easy fix for the under-representation, it would surely have been found long ago. Nonetheless, I would like to contribute to this ongoing debate with some results from recent research, set in the framework of a model for educational choice, in the hope that this structure can lead us towards some possible lines of action.

My contention at the outset of this article is that women are still "the second sex" in science, in that their participation is still limited and is seen as an exception from the norm. What is the potential contribution of these female "others" in science? Why should we seek to have more women transcend their individual, personal borders as well as the borders of scientific understanding? Why do young girls in free and enlightened societies and in the age of information technology, still shy away from the subjects and careers that are likely to shape our everyday lives and possibly the destiny of our planet?

I will look at the current situation for female representation in science and the reasons why we should seek a higher participation of women in these fields. From there I will move on to how a possible choice of a science education and career is evaluated and construed by modern young women, using the theoretical framework provided by Jacquelynne Eccles and colleagues. I will refer to research findings both from others and from two research projects I am currently involved in: The Norwegian "Lily" study (Schreiner, Henriksen, Sjaastad, Jensen, & Løken, 2010) and the international IRIS project (IRIS, 2010). Finally, I will use these findings as a point of departure for suggesting some ways forward.

Osborne et al. (2009) have reviewed research documenting that girls' disenchantment with science starts before age 14, and they point out "the need to ensure that the teaching of science in middle schools is of the highest quality and that considerable effort is needed to inform students of the potential career pathways afforded by the study of science ". This is extremely important for all of us engaged in science education to bear in mind, and it will form a backdrop for the whole of the present paper. However, in this paper I will concentrate most on what happens a bit later, when the girls (or rather: young women) are in the process of choosing post-secondary education, bringing with them experiences from school and home background into the decision process.

Before I move on, I would like to say that although I use the term "science" in the heading and often throughout this paper, the discussion is generally valid also for mathematics and the technological disciplines. Thus, most of the times where I write "science", it could easily be exchanged with "science, technology, engineering and mathematics" (STEM). Throughout the paper, my focus is on those disciplines that have a recruitment challenge and an under-representation of women. Thus, my arguments will relate mainly to the mathematical, physical and technological disciplines, and less to the life sciences.

A DESCRIPTION OF THE SITUATION

Let me give a few examples to illustrate the current situation concerning the participation of women in STEM disciplines in different parts of the world and on different levels.

The report "Europe needs more scientists" (EU, 2004) called for a substantial increase in the percentage of science and technology researchers in the total workforce, and remarked that increasing the number of women entering science and engineering careers would go a long way towards meeting this challenge. The publication "She figures" (EU, 2006) describes patterns of horizontal as well as vertical segregation by sex: Women are under-represented in research generally, and in physical, mathematical and engineering occupations specifically, and women have a lower chance than men of reaching senior levels in R&D. For instance, for the EU-27 countries, around one out of three PhDs earned in 2006 within physical science, mathematics and statistics was earned by a woman, whereas the corresponding figure for computing was around one of five (ibid).

In the USA, men earned a majority of bachelor's degrees awarded in engineering, computer sciences, and physics (81%, 81%, and 79%, respectively) in 2007 (National Science Board, 2010). Among fields with notable increases in the proportion of bachelor's degrees awarded to women were earth, atmospheric, and ocean sciences, agricultural sciences and chemistry, whereas women's share of bachelor's degrees in computer sciences, mathematics, and engineering declined in recent years (ibid).

From the 2008 "Education at a glance" report (OECD, 2008), we learn that the proportion of females among students entering tertiary science studies ranges from less than 25% in Japan, the Netherlands, Switzerland and Chile to more than 35% in Denmark, Iceland, Italy and New Zealand.

In the report "Why so few?", (AAUW, 2010), the American Association of University Women state:

> *By graduation,men outnumber women in nearly every science and engineering field, and in some, such as physics, engineering, and computer science, the difference is dramatic, with women earning only 20 percent of bachelor's degrees. Women's representation in science and engineering declines further at the graduate level and yet again in the transition to the workplace.*

WHY SHOULD WE CARE?

Does it really matter, for science, who performs the research and develops the models? Does it matter who develops the next generation of computers or the newest cancer treatment? Do we believe that women would be happier as scientists than they are as nurses? I will give four reasons why we need to pay continued attention to the recruitment of girls and women to science.

1. *STEM needs women because it needs more people in general.* This argument simply says that it is most efficient to look for recruits where the unexploited potential is greatest.
2. *STEM needs women because women bring new perspectives and ways of working.* This argument assumes that women have potential for engaging in ongoing research and development processes within science and technology, and that the values, interests and experiences they bring into the work are slightly different from those of men, as we will see in the next section. The FP7 Capacities Work Programme for Science in Society (EU, 2007) states that "the pursuit of scientific knowledge and its technical application towards society requires the talent, perspectives and insight that an increasing diversity in the research workforce will ensure. Therefore, a balanced representation of women and men at all levels in research projects is encouraged". Schiebinger (2008) provides examples of how taking gender into account has yielded new research results and sparked creativity, opening new avenues for future research. In order to create a sustainable and knowledge-based economy in an equitable society, expertise in science and technology is needed, and the

participation of both women and men is desirable. Thus, this argument goes that *science needs women* in order to develop in new ways.

3. *Women need STEM in order to influence their own life and the development of the world.* This is related to the above argument, but focus here is on women's empowerment to shape the world and the everyday life that they themselves and their children will experience. This could be related to ensuring that technology development and research priorities serve the interests of both genders. It could also be to let women partake in the wonders of the scientific and technological world – for enriching their lives and contributing to their individual development.
4. *Everyone (including women) should have a real, not only a formal, free choice of education*. By this I mean that the norms, stereotypes and expectations girls meet should allow for a role for women in STEM. Today, stereotypic views of scientists are still prevalent and fit poorly with the ideals that are held up for young women by contemporary culture. Girls will not have a real freedom of choice of education before these mental and cultural barriers are reduced.

Bearing these arguments in mind, we now move on to how young people in general, and women in particular, make their educational choices and how science is assessed in the considerations that determine their choice.

A MODEL OF EDUCATIONAL CHOICE. WOMEN'S CONSIDERATIONS

The expectancy-value model

The psychologist Jacquelynne Eccles and her colleagues have, over a period of more than 25 years, built up and refined a model of educational choice, the so-called expectancy-value model (Eccles (Parsons) et al., 1983; Eccles & Wigfield, 2002). Reflecting a complex issue with a multitude of influence factors, the model itself is accordingly rather complex – but in the research projects "Lily" and IRIS, we have found it meaningful to extract and investigate the most central constructs from the model (the ones that are, in Eccles et al.'s flow sheet, closest to the actual choice). In brief, the expectancy-value model states that educational choices are made based on the individual's *expectancy of success* within the field under consideration, and a range of values that she holds and that impinge on the choice. The values are subdivided into *interest/enjoyment value , attainment value, utility value,* and *cost*. For instance, a young woman who considers choosing the advanced calculus course in her junior year at university, asks herself: Am I good enough; will I be able to obtain a good grade? Am I really interested; do I enjoy working with maths problems? Am I a "maths person"; does it suit my identity? Will it help me reach my goals regarding future education, career and material well-being? How much will it cost me in terms of time and effort?

All these considerations are, of course, to some extent inter-related. Furthermore, they are related to other internal and external factors such as age and previous experience, family background, youth culture, zeitgeist and general trends in society, and so on. We are not forgetting that; but let us focus on these for now and see if there are gender differences in some of these constructs that may help us understand the continued low participation of women in STEM. I will draw on international research as well as results form the aforementioned research projects I am currently involved in regarding young pepole's educational choices concerning STEM disciplines. A lot of the examples will come from physics – both because this subject is representative for some of the subjects with the greatest recruitment challenge and gender imbalance, and because it is the subject where I have my own background.

Expectancy of success

In the Eccles model, expectancy of success is closely related to Bandura's *self-efficacy beliefs* (see e.g. Bandura, 1997; Bandura, Barbaranelli, Caprara, & Pastorelli, 2001).Numerous research reports have shown that girls have lower self efficacy than boys within STEM disciplines (Barnes, McInerney, & Marsh, 2005; Cavallo, Potter, & Rozman, 2004; Lyons, 2006). Häussler & Hoffmann (2000) found that for German pupils, young men's physics-related self concept was higher than their general school-related self concept, whereas the opposite was true for young women. Findings from our own research show that Norwegian girls who have chosen non-compulsory science in upper-secondary school express lower self-efficacy in science and mathematics than boys who have made the same choice. Boys agree more than girls that they learn easily in the subjects and are better at them than most other students. Girls agree more that they worry about not being good enough at the subjects (Bøe, 2010).

Zeldin et al. (2008) and Zeldin and Pajares (2000) found differences in the ways women and men develop their self efficacy related to STEM education and careers: Whereas men's self efficacy arises most strongly from actual (perceived) achievements in STEM-related tasks, women rely more heavily on interaction with others to build their self efficacy. This observation points to the importance of role models and significant others for women's choices. Moreover, Häussler & Hoffmann (2000) found that physics-related self-concept was a strong predictor of interest in physics as a school subject – thus emphasising the interaction between expectancy of success and value considerations related to educational choice. Jacobs et al.(1998) found that actual science performance was a predictor for choice of a physical science profession for young women, even after controlling for factors like family support, science-mathematics-related activities, interest in physical science, and overall grades.

Parents and teachers play a significant role for students' self-perception and expectancy of success in maths and science, thereby also influencing future educational choices (Hazari, Sonnert, Sadler, & Shanahan, 2010). A respondent in the Norwegian "Lily" survey (Schreiner et al., 2010) wrote that "My 8th grade maths teacher 'discovered' me (…) and since then I've been hooked".

Interest/enjoyment value

Eccles and Wigfield (2002) say that their interest-enjoyment value is measured like *intrinsic motivation* (Ryan & Deci, 2000), Csikszentmihalyi's (in Eccles & Wigfield, 2002) *flow*, and Renninger, Hidi and Krapp's (in Eccles & Wigfield, 2002) and Schiefele's (1999) *interest*.

What is it, then, that students find interesting and intrinsically rewarding in science? A number of interest studies in science education show that girls' and boys' interests are *different* (Cerini, Murray, & Reiss, 2003; Osborne & Collins, 2000, 2001; Scantlebury & Baker, 2007). On a general level, girls express stronger interest in issues to do with human health and well-being, whereas boys are more interested in things to do with e.g. technology and physics. A likely reason why boys develop stronger interests in science (particularly the physical sciences) than girls is that they have more childhood experiences involving science and technology (Hazari, Sadler, & Tai, 2008; Jones, Howe, & Rua, 2000; Sjøberg, 2000).

The ROSE survey investigated this question through a questionnaire to 15-year-olds in a range of countries. They found that the interests of girls differed markedly from those of boys in most countries. Whereas boys favoured "dramatic" topics like explosions and technology, girls were more interested in how to take care of the body, how to care for animals, in aesthetic topics like the rainbow and in questions of the paranormal, in why we dream at night, etc (Schreiner, 2006). We may note the tendency of young men to be concerned with the subject itself, whereas young women are interested in topics which may help them in their relations to themselves and to other people. This tendency of young women to be more preoccupied with using their STEM insight in social settings was also noted by Angell et al. (2004) for physics students. Along similar lines, Osborne & Collins (2001) found that British 16-year-olds (especially young women) emphasised the importance of science for explaining things to other people.

Also worth noting in this context is that girls appear to have other criteria than boys for feeling that they understand the subject matter. Stadler, Duit & Benke (2000) claimed that boys and girls hold different notions of what it means to understand physics: Girls think they understand a concept only if they can put it into a broader world view, whereas boys appear to view physics as valuable in itself and are satisfied if there is internal coherence among the physics concepts learned. Osborne & Collins (2001) found that girls expressed a desire to know *why* things happened in science (the causal question) rather than simply learning only *what* happened (the ontological question).

Stokking (2000) found that most physics students in the Netherlands would like a stronger orientation of the subject towards the phenomena of daily life and of the instructional approaches towards active participation. Labudde et al. (2000) suggested that such changes would be effective for improving girls' experience of physics and therefore might increase their likelihood of choosing a science career. Häussler & Hoffmann (2000) claimed that physics as it is taught in the majority of physics courses does not take into account students' interests, and they found that an interest-driven and context-rich physics curriculum was superior to the traditional physics curriculum and that it also resulted in an improved physics-related self-concept, particularly among girls.

Our own data from Norway (Schreiner et al., 2010) show that interest is among the most important reasons expressed by students for choosing a STEM higher education and that this interest may be related to positive school experiences (good teachers), exposure to popular science in the form of television programmes and magazines, and support and encouragement from family members. Again, girls evaluate the influence of *persons* on their choice as stronger than boys do.

Attainment value

Attainment value refers to how important it is for a person to succeed with a task to fulfil personal needs (Eccles, 1994). Completing a science education may be important to a person because it makes her feel happy and proud of herself (affective goals), or because she seeks the stimulation of overcoming challenges and working creatively (cognitive goals). Participating (and succeeding) in certain tasks may also serve to confirm important aspects of a person's identity.

Schreiner & Sjøberg (2007), arguing from a sociological perspective, point to the pre-eminence that contemporary society gives to the individual and claim that modern youth evaluate education against how it may contribute to their self-development. Illeris et al. argue that the traditional question 'What do you want to be when you grow up?' today addresses a more far-reaching issue than before: '*Who* do you want to be when you grow up?' (Illeris, Katznelson, Simonsen, & Ulriksen, 2002).

The "Lily" data shows that self realization is maybe the most prominent aim that beginning STEM students in Norway have for their education and career (Schreiner et al., 2010). All students, regardless of gender and strand of education, put top priority on "developing myself" and "developing my talents and abilities". However, what each individual means by "developing her/himself, may vary – and this variation shows clear gender differences along the well-known lines described above, with women seeking more "person-oriented" and idealistic values and men being relatively more concerned with technology development, leadership and management.

STEM subjects (at least the mathematical-physical disciplines) have an image - be it well-deserved or not - of being demanding, hard, masculine, traditional, decontextualised, theoretical and abstract rather than connected to societal development and human well-being (Aikenhead, 2007; Angell et al., 2004; Carlone, 2003; Osborne & Collins, 2001). Masnick et al. (2010) found that American high school and college students considered scientific professions to be less creative and less people-oriented than other popular career choices. Many students see school science as uninteresting and irrelevant to their lives (Tytler, Osborne, Williams, Tytler, & Clark, 2008), as authoritarian and abstract, and with little room for search for personal meaning (Sjøberg, 2002). This image of the STEM sector is held up against young people's (young women's) priorities and aspirations (as described above), and if it does not appear to meet their image of who they want to be, they will choose *not* to pursue an education and career in STEM.

As we have seen, a crucial question is whether young people (and women in particular) see STEM subjects as worth pursuing and STEM students and professionals as someone they can identify with or admire. Bennett and Hogarth (2009) reported that students in the 11-16 age range expressed a sense of science being important in general terms, although not having much appeal for individual students. Hannover and Kessels (2004) and Taconis and Kessels (2009) used self-to-prototype matching theory to investigate 9th-grade students' self-image and found that the students saw typical peers who preferred science subjects as less attractive, creative, socially competent etc, but more intelligent and motivated, than peers who preferred other subjects. Thus, their image of the typical science student was that of a hard-working and smart but rather boring and clumsy person (slightly paraphrased). Maybe not surprisingly, most of the students in the survey conceived of themselves as being less similar to the science prototype and more similar to the humanities prototype. Taconis & Kessels (2009) pointed to the mismatch between science culture and most students' self-image and identity to explain why few students choose to study science.

Brickhouse and colleagues (2000; 2001) have especially studied the relation between girls' identities and their experiences in school science, and argue that identity formation is essential to understanding science learning (Brickhouse, 2001). A school science or STEM career identity is unattractive to many girls. In their study of Australian year 10 students, Lyons and Quinn (2010) found that girls were especially likely to attribute a non-science choice to not being able to see themselves as scientists. They recommended that efforts should be made to better inform girls about the range of possibilities available to women in science careers. Blickenstaff (2005) also points to lack of role models as one possible reason for women's underrepresentation in science.

Persons may be important in young people's identity formation and educational choice process. Research on the effect of STEM recruitment initiatives indicates that what often makes an impression on potential STEM applicants is the personal meeting with students, teachers or professionals involved in the field (Jensen & Henriksen, 2010). Even persons without a background in STEM can serve important functions as "significant others" in the educational choice process (Sjaastad, 2010). A parent or sibling can "hold up a mirror" and help the adolescent see herself more clearly, help her identify her own strengths and articulate her values and goals, and possibly bring her attention to the wide spectrum of possibilities (including those within STEM) for a person with her interests and priorities. A STEM student in the "Lily" study (Schreiner et al., 2010) wrote: "*Grandmother has meant a lot for the kind of person I have become and has helped me set my goals, wishes and dreams for my life*". In our data material we also see indications that these personal meetings are particularly influential for girls. Baker and Leary (1995) found that "the girls with the strongest commitment to scientific careers learned to love science through the love of a parent or grandparent involved in science". Hasse and colleagues (Hasse, Sinding, & Trentemøller, 2008) found that a majority of Danish, female physicists in their sample hade been inspired to pursue a physics career by their father.

Utility value

Utility value concerns how helpful a certain task or educational choice is in reaching personal goals, such as career goals. Options that have utility value are extrinsically motivated (Ryan & Deci, 2000).

In upper secondary school, STEM subjects are often chosen for their utility value or for strategic reasons since these subjects (mathematics and physics in particular) have a “gate keeping” function for entry into prestigious higher education programmes such as medicine and many branches of engineering science. These subjects may therefore have utility value for many reasons: they can serve as qualifications for specific plans for higher education; they can raise a student’s general qualification level for university admission, and they can help in keeping many options open as long as possible. It is therefore not surprising that utility for future career often emerges an important reason for choosing these subjects in upper secondary school (Angell et al., 2004; Hutchinson, Stagg, & Bentley, 2009; Lyons, 2006; Osborne & Collins, 2001). More short-term goals also give utility value, for instance wanting to take the same course as a friend (Eccles & Wigfield, 2002).

In higher education, choosing a STEM programme for its utility value would mean that one chooses STEM because one believes it will give some kind of benefit that is not related to the intrinsic value or attainment value of the STEM education itself. This could for instance be that a STEM education was regarded as the best way to a secure job or a high income, that it was considered necessary in order to get a job in a dynamic environment or with a lot of travelling, etc. In most Western societies, it appears relatively unlikely that concerns such as these would be a strong driving force for most students choosing STEM higher education. On the contrary, STEM subjects, because of their high perceived cost (see below), are unlikely to be regarded as an “easy” way to good jobs or other benefits.

Hazari et al. (2010) use the term "outcome expectations" for values that students seek in a future occupation, such as for instance high wages, people-oriented work, etc, and they point out that there are great gender differences in these values, such that boys, more than girls, want jobs where they control others, that are easy, make them famous, give them high pay and status, and involve inventing new things etc. This is largely in line with our Norwegian results as described above, where girls aim at more "people-oriented" work whereas boys aim at technology development. Thus, given the image of science and scientists described above, girls are less likely than boys to see STEM education as the best way to reach their goals.

Cost

Relative cost refers to the negative aspects related to one activity or educational choice compared to other options. It could for example be the time and effort that is required to do well in maths compared to social science. It could be fear of failing maths, or fear of disappointing parents. Relative cost also includes lost opportunities from choosing one education over another.

STEM subjects on all levels are generally perceived as having a high cost. This is largely related to their reputation of being hard and work-intensive (Angell et al., 2004; Carlone, 2003; Osborne & Collins, 2001; Tytler et al., 2008). For students choosing science and mathematics in upper secondary school mainly for utility reasons (to get into medical school, for instance), the cost may also be considerable in terms of having to put up with a subject they find uninteresting, unattractive and ill matched to their identities.
Especially girls and women appear to perceive the costs of pursuing STEM subjects and careers to be high (Angell et al., 2004; Carlone, 2003; Warrington & Younger, 2000). Our "Lily" data also show this tendency. On an open question about the reasons why they believe

few young people (and women in particular) choose a higher education within STEM, our first-year STEM student respondents had the perceived degree of difficulty of these subjects as one of the most frequently mentioned reasons.

Summing up gender differences in values and considerations related to educational choice

As we have seen from the above sections summing up research in the framework of the Eccles model, there are gender differences in young people's considerations within all important elements of the model. Girls have lower self efficacy and perceive a higher cost associated with studying science; they identify less closely with the disciplines and the scientists associated with them; they have different interests and different expectations for their understanding within science than do boys, and they do not, to the same extent as boys, see science as a means of attaining extrinsic goals and expectations. Each of these insights carries with it possible lines of action to influence girls' considerations related to science careers and increase the participation of women in STEM. I will return to this point later.

It should be remembered that although the above description of educational choice centers around the considerations students make prior to the actual choice, the experiences, values and attitudes on which they build their choice stem from a far earlier age. We know that childhood and adolescence experiences, both in and outside of school, are important predictors of educational choice and that for the sciences, girls' disenchantment often starts from an early age (Osborne et al., 2009).

A PERSPECTIVE ON CULTURAL DIFFERENCES IN WOMEN'S PARTICIPATION IN SCIENCE

A slightly different approach to understanding the under-representation of women in science may be found in the EU-supported project UPGEM (Understanding Puzzles in the Gendered European Map). This project looked at the difference (in terms of numbers, experiences and outlook) between female researchers (from PhD students and on) in physics in five European countries and described how the career paths of female physicists are conditioned by cultural patterns both within the discipline and in society at large. For instance, the UPGEM researchers compared women in physics in Italy and Denmark and noted that Italy has a higher proportion of female physicists, and also a higher proportion of women who stay on in research after having children. The reasons they suggested for this difference included (Hasse & Trentemøller, 2008):

- *Different paths from school into higher education*: In Italy, there is an obvious path from classical (language/arts/humanities) school backgrounds into natural sciences, whereas this path does not exist in Denmark. In Denmark, according to these researchers, physics students and professionals consider themselves as a particularly clever and theoretically apt breed of people, largely removed from the hurdle of daily and political life. It is unthinkable for a student with a language or social science background from upper secondary school (as many girls have) to enter into physics studies at a university. In Italy, on the other hand, it is the students (including many females) who come from a classical languages background who are considered the most "brainy" people and who see it as a natural path to continue into university studies of for instance science or technology.

- *"Class societies" and "gender societies":* Italy is a "class society" where social background is more determining for a person's choices than gender; thus, it is experienced as natural and appropriate for a woman from the right background to go into physics, whereas Denmark is a "gender society" where individuals orient themselves after what is considered natural or appropriate to do for a person of his/her gender (and physics is, as we know, a "male discipline").

-
- *Different family patterns*: Although Denmark has much stronger official support for families with children (daycare centres, maternity leave), the responsibility for children and family is still in practice borne by women and is a matter of private negotiation in each family. In Italy, the extended family (most notably the grandparents) have a much more active and important role, facilitating the career of young female physics professionals.

- *Workplace cultures:* The UPGEM project has described different prototypical workplace cultures in physics departments and noted that what they term the "caretaker culture", where physicists work closely together as a team, is more predominant in Italy, whereas the so-called "Hercules culture", where researchers compete individually for research funding and honor, dominates in Denmark. The "caretaker culture" appears to be better matched with women's preferences and may thus be one explanation for the difference in female participation between the two countries.

Again, we see that each of these findings or perspectives carries with it possible means of influencing the considerations that make many women turn away from science – although the science education community's influence over general culture as well as workplace culture is, of course, limited.

HOW TO INCREASE THE PARTICIPATION OF WOMEN IN SCIENCE AND TECHNOLOGY

Nature or nurture?

Our look at the research results concerning important factors contributing to educational choices has shown that there are gender differences in every one of these factors. Moreover, we have seen that science workplace cultures, as well as general (national) culture, shape women's participation and persistence in scientific fields.

Could it be that these gender differences in priorities, so persistent over time and geographical regions, spring from genetic differences, for instance in mathematical aptitude, between men and women? If that is the case, it might change our view of what may be fruitful in terms of changing the pattern of "gendered" choices through recruitment efforts and curriculum innovations. I will not go into this question in any depth in this paper, but only cite two recent research reports of relevance. First, Ceci et al. (2009), discussing sociocultural and biological considerations relating to women's underrepresentation in science, concluded that:

> *The evidence indicates that women's preferences, potentially representing both free and constrained choices, constitute the most powerful explanatory factor; a secondary factor is performance on gatekeeper tests, most likely resulting from sociocultural rather than biological causes (Ceci et al., 2009).*

Moreover, research indicates that to the extent that gender differences in maths and science achievement are observed, they are small in effect size and often represent an overlap of around 90 % in the score distributions of male and female students (Hyde & Linn, 2006). Gender therefore represents a very poor sorting criterion for which individuals should be encouraged to pursue a STEM education and career.

Based on findings such as these, I think we can safely continue to look for ways in which cultural conditions may be changed in order to invite more women into science and technology. The findings presented in the previous sections give us clues concerning how to proceed with this challenge.

Self efficacy

Low self efficacy appears to be preventing many girls from choosing (and staying in) STEM. Interventions aimed at increasing the self efficacy of girls (for instance through mentoring projects) might be expected to be effective for recruiting more women to STEM. Our research group in Oslo is currently studying mentoring relationships in the Norwegian recruitment project *Enter* (2010), where university science and maths students give mathematics training to groups of secondary school students, and we hope to be able to say something about which aspects of such a project appear to have an effect – on both the self efficacy and the values that young students associate with science and mathematics.

Values

To increase the *interest/enjoyment value* that girls experience in their meetings with science and technology (notably through school science), providing *meaningful contexts* appears crucial. Girls' general interests and values – of human health and well-being for instance – can easily be used as entry points into a range of subject areas such as for instance nuclear physics (connecting to cancer treatment). Also, the work forms employed in science instruction both in schools and higher education need to include active participation, collaborative learning, and attention to connections between theoretical understanding and real-world contexts if girls are going to develop a sense of ownership and positive interest in the field.

The *cost* of pursuing a science education and career is still perceived as high – and probably deservedly so. We will not do anyone a favor by enticing young people into these fields on false premises. Rather, we might get inspiration from the Swedish campaign *Intize* (2010), where mathematics students function as mentors to high school students with slogans such as the joy of "exercising your maths muscles" – with the message that mathematics *is* challenging, but that this very fact contributes to making it attractive to pursue – in much the same way as sports-interested youth may be motivated to exercise in order to beat their own (or someone else's) previous records.

Raising the *attainment value* of the science subjects – that is, girls' evaluation of how important it is for them to be a part of the scientific community and how this fits with their view of themselves – is obviously harder than changing school science, since it is related to general societal trends. Until the science and technology subjects acquire an image which allows for and includes more diverse aims, values and outlooks – a greater diversity - many girls will probably continue to see science as an area that is ill matched to their view of themselves and who they want to be. Female role models are often advocated as a solution to this problem; however, the effect of role models on young people's educational choice process appears hard to document, as noted by for instance Hazari et al. (2010).

Personal meetings and "significant others"

What does appear to have an effect, is the personal meeting with a mentor or even a so-called "significant other" (parent, sibling, teacher, youth club leader,…) who knows the adolescent and is willing to help her clarify her goals and her personal strengths and interests (Sjaastad, 2010). This is particularly important for girls, who rely more than boys on personal relations and advice. (Baker & Leary, 1995; Schreiner et al., 2010). Again; mentoring programs appear to be a good way of providing such support. Moreover, a possible strategy might be to make parents, teachers and others with whom young people relate, aware of the important role they can play in helping the youngsters make their educational choice, and to alert these "significant others" to how science and technology actually may accommodate a range of different types of work and people with a range of values and aims. Teachers are in a unique position to communicate such information to young people.

Workplace culture

As we saw from the UPGEM project (Hasse & Trentemøller, 2008), workplace culture may be an important factor shaping the retention of women in STEM careers, and is likely to "trickle down" and contribute to shaping the image of these fields, thereby affecting recruitment as well. Thus, attention to workplace culture appears necessary in order to understand and address the issue of women's participation. Hazari et al. (2010, p. 17) remark:

> *Anyone who has a physics background or has worked with physicists knows that there is truth to the claim that the physics culture promotes "physics for the sake of physics." The benefit of this cultural standard is that those who end up participating usually love the theoretical basis of what they do. This internal drive is important for motivating the large amount of dedication needed to become a cutting-edge physicist who pushes the boundaries of our knowledge. However, there is a fundamental imbalance in this norm because mainly those who come from backgrounds with the luxury of affording knowledge-based motivations will opt into physics. Others who have additional motivations, like socio-economic concerns, will need to have a passion for physics above and beyond the norm in order to disregard such concerns and opt into physics.*
> *[…]*
> *Perhaps if the physics community promoted and supported more balanced motivations, physics would be more successful in attracting members of under-represented groups.[..] [O]ther areas, such as the humanities, do not carry the stereotype that you have to give up your "life" to be successful.*

Nothing new under the sun?

As the reader may have noticed, most of these suggestions are by no means new – they have been forwarded (in various forms) through several decades. However, since the situation is still far from satisfactory and recruitment of both women and men to STEM is still a pressing issue, we have to continue to focus on the proposed solutions and to implement them and evaluate what appears to work in practice. As we as researchers progress in our understanding of the experiences, values and considerations that lead up to young people's choice of education, we will be able to elaborate on the proposed solutions and to have a more fruitful dialogue with stakeholders who can contribute to implementing changes.

Note also that many of the proposed solutions meant to increase the participation of women may work equally well to recruit and retain more diverse groups of young men (Labudde et al., 2000). I know of no evidence from research that implementing the changes that are assumed to increase women's participation, would function to turn men away. To the contrary, the proposed measures are likely to increase the diversity of personalities that may feel attracted to science and to scientific and technological careers so that the future workforce within these fields will not only be greater in numbers and more even in gender distribution, but will generally include a greater multitude and variety of outlooks, experiences and aims. My contention is that this will be possible without compromising the basic requirements of all high-quality science education and scientific research and development, such as critical reflection, mathematical rigor (where appropriate), careful examination, attention to evidence, etc.

Finally, we must not forget that although I have described a range of instances where women – on average – prioritize slightly differently form men, the diversity of outlooks among women, and among men, is very great so that gender in itself is a poor predictor of, for instance, interest in chemistry or self efficacy in mathematics. There are, of course, women whose priorities resemble the typically male outlook rather than the female – and men who prioritize more like the average female.

SUMMARY AND CONCLUSION: REVISITING CURIE AND BEAUVOIR

Thinking back to the story of Marie Curie at the outset of this paper, I think we may say that female pioneer as she was, she entered the discipline of physics largely on the premises of men (how else could she?). Although she displayed classical "feminine" traits for instance through her engagement in using radiation in the treatment of wounded soldiers during World War I, there are also indications that she was one of those women who are in many ways comfortable with the "physics culture". For instance, she is quoted as having said that "In science we must be interested in things, not in persons" (http://en.wikiquote.org/wiki/Marie_Curie). This was 100 years ago, at a time when the female participation in science and technology was only a fraction of what it is today. Today, as we have seen, science and technology (and society) might benefit from a greater diversity than just "white, middle-aged men of both sexes"; we need more diverse attitudes, outlooks and ideas.

Remember also Beauvoir's description of how women were construed to have no drive or urge to develop their faculties to the fullest and to transgress boundaries (Pilardi, 1999). Results that I have presented here, show that at least on a superficial level, this is not the case: Both young women and men, across a range of academic disciplines, have self realisation and personal development on top of their list of motivation factors for pursuing higher education. However, it appears that far more men than women see *science* as a means of fulfilling that ambition. The STEM field is in many ways still a man's culture, and it appears to be a far more natural choice for a young man to go into science than it is for his sister.

We need to do away with the assumption that only one set of values and goals, only one kind of (inborn) disposition, defines what a scientist is and should be. Paraphrasing Beauvoir and focusing on the positive possibilities, we might say that "One is not born a scientist, but becomes one". There is no single determining factor to define who is suitable to go into science; the skills needed in order to make valuable contributions to science and technology can be acquired by a far greater number (and variety) of persons than those who have up to now dominated the scientific and technological enterprises.

As science educators we should communicate as best we can that a range of different values, goals and experiences can fruitfully be brought into the scientific and technological enterprise, sparking new ideas and new applications of knowledge, for the benefit of the individual (who experiences self development and fulfilment) and for society.

ACKNOWLEDGEMENTS

I am indebted to my colleagues in my research group at the University of Oslo; without the discussions we have had and the work we have done together, this article could not have been written. Thank you, Camilla Schreiner, Maria Vetleseter Bøe, Fredrik Jensen, Marianne Løken, Jørgen Sjaastad and Svein Sjøberg.

The work behind this paper was in part made possible through financial support from the Science In Society programme in the Seventh Framework Programme for Research of the European Commission.

ABSTRACT

Amount of information and resulting knowledge needed for competitive inclusion of any individual or institution into knowledge society is rising constantly. At the same time, life span of knowledge is decreasing. Lifelong learning is playing a very important role in modern times as almost any individual, regardless of age or profession is required to constantly gain new knowledge. Changes and adaptations to traditional learning methods and educational systems are needed in order to eliminate the divide between those that have the knowledge needed and those that don't.

Changes and adaptations of educational systems are very much related to ICT (Information and Communication Technologies). ICT can act as a tool that fosters these changes, aldo changes in educational systems should be implemented because of completely different (non ICT related) reasons. Supporting ICT and Multimedia are in many cases mature enough to be systematically introduced into educational process. It is not only about making education more appealing, but also about increasing effectiveness in education. Use of ICT is oriented towards constructive learning, whereas in many cases learning goals can be achieved easier and faster. Use of ICT in education also decreases digital divide and increases competitiveness of work force.

In this article all aspects of systematic ICT introduction into education are presented. Necessary organizational changes as well as modern pedagogical approaches, enabled by the use of ICT, are described. The article focuses on the changing role of educational practitioners and presents complete ICT and multimedia supported educational system, ranging from technologies, virtual and real environments as well as to content and support needed. The components of the system are supported with case examples. Important issues that prevent necessary changes of educational systems on the bigger scale are described and commented.

EDUCATIONAL SYSTEM TODAY AND TOMORROW

Existing formal educational system was first established in the mid 19th century. As industrial society was under development, the system delivered only basic knowledge and skills. It was mostly oriented towards forming the working force. Knowledge needed at the work place included only repetitive activities and didn't change in the life time of an individual.

Since then, the basic concept of the formal educational system didn't change much. In the 20th century it was only expanding in quantity of knowledge transferred from educational practitioners to learners, however it was still designed according to the principle "one size fits all". All learners were treated as the same, given same content and same didactical methods.

Today we are becoming more and more aware, that individuals have different talents, characters and different interests related to our work and education. Formal educational system has not adapted, formal curricula still consists of mostly repetitive knowledge/skills and does not adapt to the needs of the modern society, meaning to the needs of the industry environment and of the future work places on any positions. Thus, the credibility gap is expanding as expectations and demands of the employers vary from the actual knowledge and skills acquired by the current and future employees.

Another issue, which needs to be tackled is the existing knowledge assessment system, which is in many cases out of date, as it only checks repetition abilities of known facts up to the certain degree (in percentage) that should be sufficient for professional qualification.

One of the main findings of the 2009 ONLINE EDUCA conference, the worlds main event in ICT supported education was that existing educational systems in Europe are in many cases not capable to offer the "vision of the world" but only to present "the world as it is".

The statements introduced above call for the introduction of changes and adaptations of formal educational systems. Pedagogical approaches and content provided should be adapted to the specific needs and expectations of individual learners. Plurality should be encouraged and all who dare and are able to think different from the uniform majority should have incentives from the educational system. It is therefore crucial to identify and distinguish "ability to memorize and learn", the skill that can be learned, from "talent", the exceptional characteristics of individuals. Adaptations of formal educational systems call for organizational changes, which should foster individuality. At the same time they should be able to respond quickly to transformations of the modern society, which appart from the individuality stress the importance of the collaborative or collective learning and work on all fields.

INNOVATIVE PEDAGOGICAL APPROACHES AND ICT (TEACHERS DON'T TEACH, THEY MODERATE!)

Adaptations of the educational systems depend on the introduction of the innovative pedagogical approaches which are in most cases based on knowledge construction. Knowledge construction can be performed through different forms of collaborative and project work that end with specific result (product, document, presentation, etc).

Unlike in the past, ICT tools and services that can be used in the learning process enable widespread introduction of such methods and represent good motivational lever. Reduction of time needed to acquire learning goals is another positive aspect of using ICT in the learning process. ICT enables simple creation of constructive learning process results and products as user generated content. Another advantage of ICT use is the capability of simple, time and space independent sharing of results with other learners.

Innovative pedagogical approaches can be performed through lessons in which lesson specific content is represented through multimedia, whereas ICT acts as the learning tool. One example of such lessons can be game based learning (GBL). Digital games have great motivational potential. Apart of using most up-to-date ICT equipment, high quality educational games consist of interesting interactive and multimedia content that immerses the player into the virtual world of the game. Various types of existing games (e.g. multiplayer, repetitive, role playing, adventure) can be effectively adapted and used in the educational process to support constructive learning methods.

Constructive learning methods that can be performed with the use of modern ICT terminal equipment (e.g. electronic boards, tablet PC, smart readers and phones), didactical software, multimedia interactive content and knowledge assessment software enable knowledge building through constructing and sharing learning process results. These methods also enable acquisition of soft skills, not necessary related to the content of learning, such as working and collaborating in teams, selecting relevant information, decision making and last but not least becoming familiar with various techniques of learning.

Constructive learning methods require the change of the learning practitioners role. In this concept teachers don't teach. They moderate and support the learning process. This change reflects in the preparation as well as performance of each lesson. In most occasions learning practitioners are required to be more innovative, to spend more time for preparation and less time for repetitive activities. In order to implement adaptations and changes described, the whole educational system should be adapted. The work load of learning practitioners should be reevaluated, administrative and other non pedagogical activities activities should be simplified. Most important, teachers should be properly supported to address new pedagogical challenges and demands of the modern society.

EDUCATIONAL SYSTEM AND ICT (E-SCHOOL IS NOT A VIRTUAL SCHOOL!)

ICT can act as the supportive tool in order to foster implementation of adaptations described in the previous chapters. When describing ICT supported education, two layers need to be addressed:

- learning practitioners layer
- learning participants layer

Learning practitioners need to be trained and supported to use ICT effectively. ICT tools, services and content to be used in their classrooms should be treated like any other accessory teachers use within their lessons. ICT for learning participants on the other hand should be embedded or seamlessly integrated in their learning process. For this purpose set of web based tools should be available for them to use in or outside of the classrooms. Following chapters describe training and e-competency challenges as well as four necessary components of ICT introduction into educational system:

1. Multimedia learning content
2. Web based virtual learning environment
3. Technical and didactical support

4. Cooperation with research and development sector and academia

E-COMPETENCY REQUIREMENTS

Learning practitioners need to be properly trained in order to use ICT tools, content and services effectively. Acquisition of ICT competences for teachers differs from regular digital literacy trainings offered to the rest of the population. For teachers, it is important to know how to use technologies, services and solutions introduced into learning process. ICT is just the tool, only when it is used properly, added value to the learning process can be achieved.

Teachers training should be therefore performed in two levels. The first level is independent of the subject area and is very much similar for all learning practitioners. It needs to be performed modularly, through blended learning (live and by distance). Duration of the training should be one or two semesters depending on the types and extent of modules chosen by the teachers.

The main aim of the first level of training is to enable teachers to perform their lessons through selected innovative learning method with the use of ICT.

Advanced or second level of teachers training should be related to the use of specific ICT tools in their subject area. These trainings are commonly performed in shorter practical workshops with the focus on use cases and adaptations of the chosen ICT tool and selected learning method.

When competency requirements of majority of learning practitioners are not met, the success of ICT introduction into the learning process is limited to early adopters, enthusiasts and progressive teachers. There are cases where governments invest substantial amount of financial resources into ICT in education without getting satisfying results. This is due to the fact that they invest in provisioning infrastructure and technologies and are not giving enough focus on teachers competences. In long term this may even cause negative consequences. Instead of decreasing digital divide among learning participants, it may grow bigger as it depends on individual learning practitioners and their personal interests in using ICT in their learning process.

Digital literacy of learning participants is equally important. It has different focus as it needs to be related to the soft skills needed to select, evaluate and extract relevant information, acquired from digital and other approved or non approved information sources.

Multimedia Learning Content

Multimedia learning content represents an alternative to existing content in the educational process. It is appropriate to develop digital content in cases when it can be effectively presented visually and when interactivity that has added value can be implemented. In these cases, multimedia content may help in better understanding. It may also open new aspects of the topic learned, which couldn’t be presented in the classical textbooks. Enabling learners to interact with the content is equally important. Finally, multimedia content is available from anywhere and anytime, whereas the printing and distribution costs are much lower compared to classical learning material.

There are three basic types of multimedia content:

- Professional e-schoolbooks (e-courses, covering all subject areas)

- Specific multimedia content used with specific ICT tool and for specific subject category (e.g. electronic boards)
- User generated content (created by learning practitioners and learning participants)

All three types of multimedia content need to be supported. E-schoolbooks should be made professionally [http.//www.e-gradiva.si/]. Evaluation and validation processes should be defined and included. Specific multimedia content exceeds the scope of e-schoolbooks, however, their existence is crucial in order to use the available infrastructure and ICT terminals effectively [http://qfk.ltfe.org/]. Their introduction should be directly related to the introduction of specific ICT equipment. No ICT equipment, tools, terminals or similar should be introduced without clear vision of provisioning adapted multimedia content.

The concept of user generated content has proven to be one of the main drivers of Web 2.0 evolution in the past. As end users were able to develop and share content simply by themselves, Internet and belonging services started to be used actively, reaching almost any user anywhere in the world, regardless of their age or occupation, wherever the infrastructure was available. Therefore it is expected to be one of the dissemination drivers in the ICT supported education as well. User generated content should be supported by set of simple web based content development tools available to learning practitioners as well as learning participants[http://coome.ltfe.org/].

WEB BASED VIRTUAL LEARNING ENVIRONMENT

Virtual learning environment should consist of set of distributed web based applications that can be described from the users perspective as two main entities:

1. National Educational Portal (applications enabling access to data, information, content and knowledge
2. Learning Environment (applications enabling performance of the learning process)

National educational portal consists of set of vertical portals, provided by public educational administration, educational industry or independent initiatives, enabling community establishment (learning practitioners and participants, principals, parents, policy makers, industry, etc.), access to multimedia content (learning objects) and access to different administrative activities. One example of vertical portals could be video educational portal, enabling upload, editing and access to video learning objects to be used in the learning process [http://www.sitv.tv]]. Another example would be electronic board portal, enabling access to content and support for the use of electronic boards.

National educational portal should provide access to technical and pedagogical support and environment for connecting all stakeholders (pedagogues, parents and policy makers). Another important component is smart and personalized search engine, providing access to national repository of learning objects as well as validated repositories around the world.

Learning environment consists of set distributed applications enabling learning process to be conducted over the web. The key activities supported should be content development, virtual classrooms, set of collaboration and communication tools, electronic knowledge assessment (testing), e-portfolio building, progress tracking and finally constant evaluation of the activities performed [http://www.e-cho.org].

TECHNICAL AND DIDACTICAL SUPPORT

Apart form the content related issues and learning process supporting tools, there is another crucial component of successful ICT introduction into learning process that targets learning practitioners. The appropriate technical but especially support should be provided systematically through well defined organizational model that includes consulting to learning practitioners. This model should include competent institutions, ranging from educational industry, consulting companies, expert individuals, as well as schools themselves. The model should promote institutional cooperation, based on clearly defined projects with learning practitioners. Evaluation aspects and constant quality assessment should also be integrated.

Support can be conducted over the communication and collaboration tools within the national educational portal or through set of consultations. However, best results are achieved when performance of ICT supported lessons by learning practitioners is monitored by experienced consultants in the form of mini projects.

COOPERATION WITH RESEARCH AND DEVELOPMENT SECTOR AND ACADEMIA

The field of ICT use in education is very dynamic. It changes and adapts constantly as new technologies are introduced and methodologies of their use are discovered. It is virtually impossible for educational system to follow trends and new findings, without systematic cooperation with academia and interdisciplinary R&D sector. This cooperation needs to be defined systematically, through set of pilot projects introducing new methods of ICT use in education. The focus should be on evaluation and dissemination, so that best cases would be introduced into the ICT supported learning system and performed on the wide scale.

CONCLUSION

ICT tools, services and solutions are mature enough to be introduced into the learning process systematically and used by other learning practitioners than enthusiast only. The reasons for expansion of ICT use are numerous, apart form making the learning process more appealing, ICT may support easier achievement of learning goals, increase in digital literacy and consequently in the competitiveness of the modern work force.

ICT introduction affects various existing business processes in education. Later should not adapt because of ICT but due to non ICT related reasons, explained in the article. The process of introduction of modern technologies is alive and never really ends. It needs evaluation, monitoring and constant adaptation. It is comprehensive and interdisciplinary. As such it needs systematic approach, enough human as well as financial resources available.

Public education administration and policy makers need to jump on this rapid train of technology development and become part of the leading edge. They shouldn’t enforce solutions, concepts and their views, but they should systematically moderate and support innovation in the educational process.

Authors of the article have many years of experience in implementing technologies as well as supportive solutions enabling effective ICT introduction into educational system [http://www.ltfe.org/]. During our previous work with different target groups of users we came to the conclusion that if educational system will not adapt to new, emerging paradigm in education, the parallel structures will be established by learners themselves, leaving teachers and educational system behind and even increasing the existing credibility gap.

ABSTRACT

ROSE is an international comparative study that investigates the diversity of interests, experiences, priorities, hopes and attitudes that children in different countries bring to school or have developed at school. The underlying hope is to stimulate an informed discussion on how to make science education more relevant and meaningful to students in ways that respect gender differences and cultural diversity. We also hope to shed light on how to stimulate interest in S&T-related studies and careers. ROSE has developed, after consultation with science educators from all continents, an instrument that tries to examine the attitudes of 15-year-old students. The ROSE instrument has around 250 single items – simply worded questions or statements requiring responses on a 4-point Likert scale. This enables the use of standard statistical methods like calculations of means and correlations. About 40000 students from 35 countries took part in ROSE, and about 10 PhD students from different countries will base their theses on ROSE data. Schreiner & Sjřberg (2004) report fully on the project rationale, development and logistics. Additional information, including reports on data collection from the participating countries, is available on the ROSE website. Several comparative articles and international reports have been published and more are planned.

INTRODUCTION

In many highly developed countries, there is a noticeable decline in the recruitment of students to science and technology (S&T) studies. 'Europe needs more scientists' is the title of a report by the High Level Group on Increasing Human Resources for Science and Technology in Europe (EC, 2004). This report examines the condition of S&T in the European Union and pays special attention to the number of people entering S&T education and careers. The title of the report reveals the point: the falling recruitment to S&T studies is seen as a large problem in most European countries. The same tendencies are noted in the USA and in most other countries in the Organisation for Economic Cooperation and Development (OECD).

It is a paradox that the most S&Tdriven economies in the world are experiencing a lack of interest in S&T studies and careers among young people. The economic significance to a country of a high number of skilled scientists and engineers is well accepted. But young people do not choose their studies or careers because it is good for the domestic economy. Instead, they base their choices (when they have such choices) on their own interests, values and priorities. It is obvious that S&T studies and jobs no longer have the appeal in wealthier countries that they had some decades ago.

The lack of interest in S&T in schools and further studies is not only a problem for the economy, but also a threat to democracy, as most decisions in modern societies are highly dependent on considerations that involve weighing scientific arguments against value judgements. A scientifically illiterate voting population can be easily manipulated by propaganda.

For these reasons, it is important to understand the S&T-related attitudes, priorities and interests of the young generation: this is what the Relevance of Science Education (ROSE) study aims to do.

POSITIVE PERCEPTIONS OF S&T IN SOCIETY

When we note the lack of interest in S&T studies and careers in some countries, the first and most obvious hypothesis might be that young people in such countries have negative or hostile attitudes towards S&T. Such assertions are often voiced in public debates. S&T is blamed for many of the evils of modern societies, like pollution, destruction of the environment, overuse of natural resources and even modern warfare and conflicts. Do young people really base their attitudes on such assumptions?

Several questions in the ROSE study shed light on this question. The results indicate that there is no general hostility against S&T among young people, neither in rich nor poor countries; generally, positive responses were received to statements such as:

- Science and technology are important for society
- A country needs science and technology to become developed
- Science and technology will find cures to diseases such as HIV/AIDS and cancer
- Thanks to science and technology, there will be greater opportunities for future generations
- Science and technology make our lives healthier, easier and more comfortable
- New technologies will make work more interesting
- The benefits of science are greater than the harmful effects it could have
- Science and technology will help to eradicate poverty and famine in the world
- Science and technology are the cause of the environmental problems.

"Science and technology are important for society."

"I like school science better than most other subjects."

Figure 1

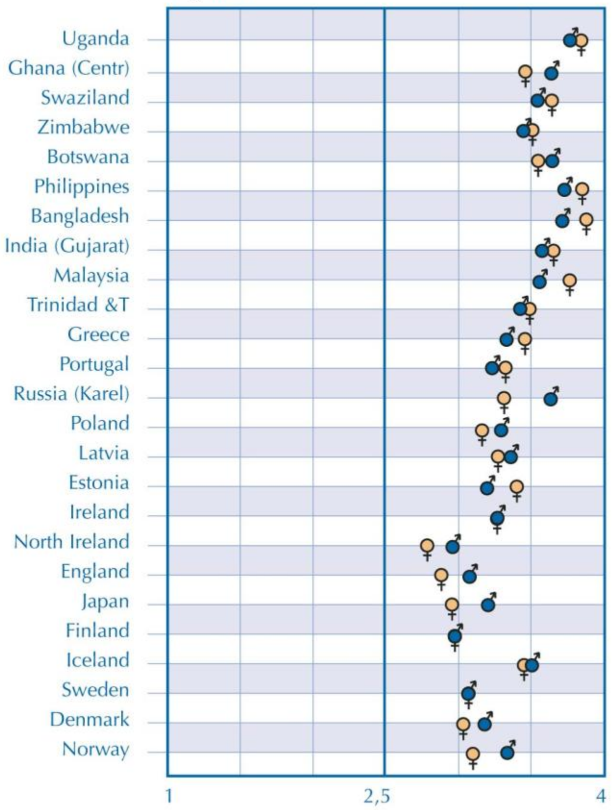

Figure 2

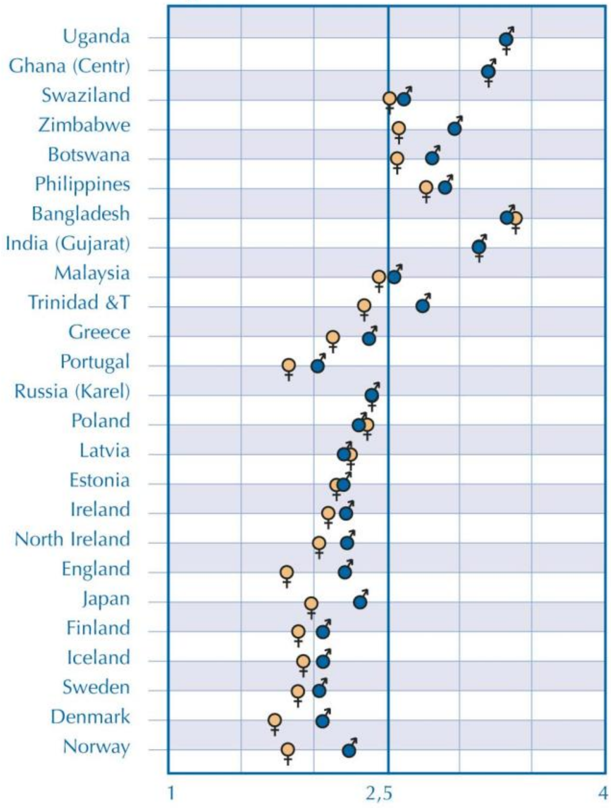


ROSE data showing mean values for girls (open female symbol) and boys (filled male symbol). The scale goes from 1 (disagree) to 4 (agree). Hence, 2.5 is a neutral response, marked with a vertical line. For some countries, only certain regions took part: in Ghana, only the Central region; in Spain, only the Balearic Islands; in Russia, only Karelia. India is represented by the region of Gujarat

Most students (aged 14-16) in most countries agree to statements like those listed above, although there areinteresting differences between nations and between girls and boys. In general, boys are more positive (or less sceptical?) than girls about S&T, and pupils in developing countries are more positive than pupils in richer countries. But it is important to note that the overall attitude towards S&T is positive.

As illustrated in Figure 1, girls and boys in all countries show pronounced agreement with the statement "Science and technology are important for society". Children in developing countries agree more strongly. Gender differences are rather small.

PROBLEMATIC ATTITUDES TO S&T IN SCHOOLS

Although students in all countries of the role of S&T in society, the attitudes to S&T in schools are more mixed.

As Figure 2 demonstrates, there are large differences between how much students in different parts of the world like school science. In general, students in developing countries like school science very much, whereas students in richer parts of the world are more negative. We also note large gender differences: in some countries, girls dislike school science more strongly than do boys. ROSE also includes a series of questions about how students have benefited from school science, but space restrictions prevent us from detailing these here.

BACKGROUND

ROSE (Relevance of Science Education)

ROSE is an international comparative study that investigates the diversity of interests, experiences, priorities, hopes and attitudes that children in different countries bring to school or have developed at school. The underlying hope is to stimulate an informed discussion on how to make science education more relevant and meaningful to students in ways that respect gender differences and cultural diversity. We also hope to shed light on how to stimulate interest in S&T-related studies and careers. ROSE has developed, after consultation with science educators from all continents, an instrument that tries to examine the attitudes of 15-year-old students. The ROSE instrument has around 250 single items – simply worded questions or statements requiring responses on a 4-point Likert scale. This enables the use of standard statistical methods like calculations of means and correlations. About 40000 students from 35 countries took part in ROSE, and about 10 PhD students from different countries will base their theses on ROSE data. Schreiner & Sjøberg (2004) report fully on the project rationale, development and logistics. Additional information, including reports on data collection from the participating countries, is available on the ROSE website[w1]. Several comparative articles and international reports have been published and more are planned.

RELUCTANCE TO ENTER S&T CAREERS

Many ROSE items ask young people about the plans and visions they have for the future. Here, we only give the responses to two simple questions: whether the student wants to become a scientist (Figure 3), and whether the student wants to work in technology (Figure 4).

As illustrated in Figure 3, there are dramatic differences between the responses from students in rich and in developing countries. In developing countries, students have a strong desire to become scientists, whereas students in most OECD countries are reluctant, with average responses of less than 2 on the 4-point scale. We also note the strong gender pattern, particularly in wealthier OECD countries. In many of these countries, the average response for girls is around 1.5, indicating that most of them strongly reject the idea of becoming scientists.

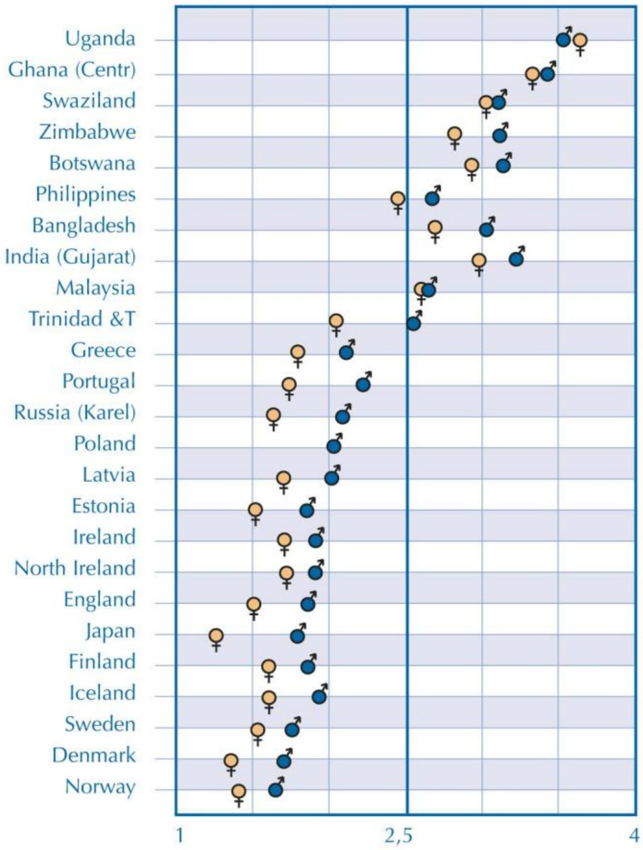
In Figure 4, we see a similar, but even stronger, pattern: working in technology seems to have a much stronger appeal in developing countries than in rich countries. In many wealthy countries, the average response from boys is close to the neutral line (2.5), but the responses from girls are strongly negative. We also note that in Japan, girls and boys are more negative towards working with technology than are students in any other country.

CONCLUSIONS

This short article gives an indication of the data and information emerging from the ROSE study. We have only presented summary statistics for four of the 250 items; more details and advanced analysis will be available on our websitew1. The first PhD based on ROSE data has recently been presented (Schreiner, 2006), detailing the analysis of the interests young children have in different topics in science and technology. Based on this analysis, a typology of students is suggested.

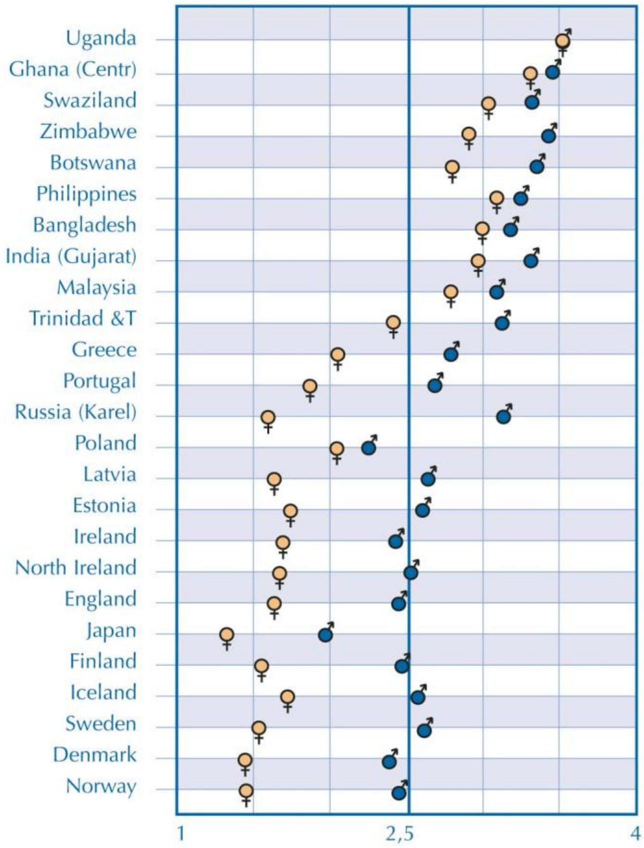
"I would like to become a scientist."

Figure 3



"I would like to get a job in technology."

Figure 4



ROSE data showing mean values for girls (open female symbol) and boys (filled male symbol). The scale goes from 1 (disagree) to 4 (agree). Hence, 2.5 is a neutral response, marked with a vertical line. For some countries, only certain regions took part: in Ghana, only the Central region; in Spain, only the Balearic Islands; in Russia, only Karelia. India is represented by the region of Gujarat

Through ROSE, we hope to stimulate an informed discussion on important aspects of S&T and its role in society and in education. Researchers from many cultures are involved in the research and discussions about issues of common concern. International cooperation, networking and capacity building are also intrinsically important. Our hope is that S&T education will be an instrument not only to promote material development and well-being, but also to address basic human values.

ABSTRACT

This communication introduces one innovative strategy for overcoming scientific, moral and cultural constraints and difficulties of human reproduction and sexuality teaching. To do this, we have implemented sequences and workshops for pupils of the first level of secondary school and educators, including teachers and inspectors of primary and secondary schools and specialists of biology didactics). Sequences of sensitization helped lead the questioning on human reproduction and sexuality education. All questions have been boosted by the establishment of a specific website, structured as a wiki interface. This website takes into account didactics dimensions. This approach met the expectations of pupils and helped to enrich scientific knowledge of the reproductive system, while developing an approach to health promotion and sex education in its broadest sense. The strategy used is an example of a teaching that shows how pupils, teachers, inspectors and didacticians can interact in a complementary fashion.

KEYWORDS: *Sex education and Human reproduction, Didactics, Wiki, Conceptions, Health promotion.*

1. INTRODUCTION

Sex education is a term used to describe education in a broad way about human sexual anatomy, sexual reproduction, sexual intercourse, reproductive health, emotional relations, reproductive rights and responsibilities, abstinence, contraception, and other aspects of human sexual behavior. Common avenues for sex education are parents or caregivers, school programs, and public health campaigns. Sexuality concerns the human being as a whole; it has a multidimensional impact (Pelege & Picod, 2006). Sexuality in many countries, particularly countries characterized by religious faith remains a taboo subject. Yet, this human dimension raises many questions for social scientists which may be interesting to consider in a process of education and more particularly to health education (Berger et al. 2006; Abdelli & Abrougui, 2005, 2006; Abrougui et al. 2006, 2008).

2. METHODOLOGY

2.1 Workshop outreach and data collection

Three types of workshops were organized:
First, workshops for pupils at the first level of secondary school have been carried out during sequences in health clubs. Teachers' interventions were very brief. Pupils were asked to participate to a WebQuest and to submit their result on a wiki which had been specially designed for this purpose.

Second, workshops for a group of pupils and teachers were held in sequences in health clubs. These workshops explained how to distribute the questionnaire and collect responses.

Finally, workshops for a group of trainers (teachers and inspectors of primary and secondary schools and specialists in didactic of biology) were held during sequences of courses and workshops. Trainers were asked to consult students' responses to questionnaires group them according to a classification grid and respond according to three criteria. All their actions are directly integrated on a website specially designed for this purpose. The workshop aimed to describe approaches to improve collaborative learning. We gave advice how to conduct a learning session combining Wiki and an appropriate WebQuest.

2.2. Webquest and wiki

A website, including a WebQuest and a wiki, have been specially designed for the purpose of this research. A WebQuest is an inquiry-oriented lesson format in which most or all the information that learners work with comes from the web. The model was developed by Bernie Dodge at San Diego State University in 1995 with early input from SDSU/Pacific Bell Fellow Tom March, the Educational Technology staff at San Diego Unified School District, and waves of participants each summer at the Teach the Teachers Consortium (retrieved from http://webquest.org/index.php, Dodge (1995),)

Since those beginning days, tens of thousands of teachers have embraced WebQuests as a way to make good use of the internet while engaging their pupils and students in the kinds of thinking that the 21st century requires. The model has spread around the world, with particular enthusiasm in many countries. Since it was first developed, the WebQuest model has been incorporated into hundreds of education courses around the world. WebQuests provide an authentic, technology-rich environment for problem solving, information processing, and collaboration. This inquiry-based approach to learning makes excellent use of internet-based resources by involving students in a wide range of activities. WebQuests are designed to use learners' time well, to focus on using information rather than looking for it, and to support learners' thinking at the levels of analysis, synthesis, and evaluation as pupils or students work collaboratively to solve a real world problem or complete a task. Each team member assumes roles that best represent some aspect of reality. Pupils or students engage in problem-solving investigations to construct their own knowledge.

What makes WebQuests so appealing is that they provide structure and guidance for both students and teachers. All WebQuests should include the same basic elements to achieve clarity of purpose and efficiency (maximum use of time and computers). According to Dodge (1995), the basic elements or critical attributes are listed as follows:

1. **Introduction:** The introduction sets the stage and provides some background information ;
2. **Task:** The task should be interesting and doable ;
3. **Information Resources:** This element includes such resources as web documents, experts available via e-mail or conferencing, searchable databases on the net, and books and other documents physically available in the learner's environment ;

4. **The Process:** This element clearly describes the steps for the learner to accomplish the task ;
5. **Guidance:** This step describes how to organize the information acquired by using guiding questions, or directions to complete organizational frameworks such as timelines, concept maps, or cause-and-effect diagrams ;
6. **Conclusion/Evaluation:** This step brings closure to the activity, reminds the learner what he has learned and encourages him to extend the experience into other domains.

Some non-critical attributes of WebQuests include group activities, motivational elements such as role-playing, a possible scenario to work within, or simulated e-mail persons to communicate with. WebQuests can be designed within a single discipline or they can be interdisciplinary (Abrougui et al., 2008). Our research team has been working on extending the original idea of WebQuests using a didactic approach. This paper presents a use of WebQuests for teaching human reproduction and sex education.

A wiki is a type of website such as Wikipedia that lets anyone create and edit its pages, enabling fast and easy collaboration (Leuf & Cunningham, 2001). A wiki enables documents to be written collaboratively in a simple markup language using a web browser. A single page in a wiki website is referred to as a ”wiki page“, whiles the entire collection of pages, which are usually well interconnected by hyperlinks, is "the wiki". A wiki is essentially a database for creating, browsing, and searching through information. A wiki promotes meaningful topic associations between different pages by making page link creation almost intuitively easy and showing whether an intended target page exists or not. In a wiki, people can write pages and edit content together. This can facilitate abuse of the system. Private wiki servers require user authentication to edit pages, and sometimes even to read them.

For the WebQuest and the wiki, in didaquest.org website, we used a wiki powered by **MediaWiki**, copyright (C) 2001-2009, version 1.15.1, under the terms of the GNU General Public License

2.2. Target audience

With the objective of non-formal education, a WebQuest has been established and was administered in a health club. This activity has mobilized the participation of a number of teachers, students and others (summarized in Table 1):

- Two **B**iology **T**eachers (**TB**), head of the health club and guiding the implementation of this WebQuest by the pupils. Those teachers are responsible for clarification, explanation and guidance of the various activities carried out.
- 39 pupils in the ninth level of Basic Education College of Tunisia (last year of the first level of Tunisian secondary school). These pupils were all "**P**upils **L**eaders of **W**ebQuest” (**PLW**) because they have participated, through various missions, activities that have enabled the evolution of this WebQuest by referencing or data collection. These pupils were divided into two classes of health club:
  - The class C1, composed of 23 pupils. They were assisted by a Biology teacher (SVT teacher). They have participated, not anonymously, in this WebQuest ;
  - The class C2, consisting of 16 pupils. They were assisted by a SVT teacher. They participated anonymously in this webquest ;
- **U**nquantifiable number of **P**eople (**UP**). These are the people who contributed to enrich the information obtained through the development of this WebQuest by their questions, comments or even by their explorations of topics and activities available to bet. During this research, the UP is mainly composed mostly of pupils from the same Tunisian school or belonging to a relationship of 21 **PLW** ;
- **E**valuators of the **W**ebQuest (**EW**). To assess the relevance of this WebQuest an assessment category was made available to all persons wishing to make an assessment. Among the **EW**, 10 inspectors in training were asked to evaluate this WebQuest.

Table 1: Target audience by gender and assigned activities.

</table>

2.3. WebQuest: Sex education in a Arab-Muslim context

In this research, to facilitated teaching human reproduction and sex education, we have adopted a WebQuests “L'éducation à la sexualité dans un contexte arabo-musulman”(Sex education in a Arab-Muslim context). This WeQuest extending the original idea of webquests using didactic approach. The basic elements or critical attributes are divided in 7 sections listed as follow (Table 2):

1- Title and presentation section; 2- Teacher section; 3- Pupils section; 4- Production section; 5- Disciplinary section; 6- Authors section; 7- More information. section

Each section corresponds to a specific public (Table 2). For more clarifications about this sections consult the Webquest at didaquest.org website:
http://www.didaquest.org/wiki/Portail:Sexualite

2.3.1. Webquest task « mission »

For convenience, and to make it interesting and feasible, the mission has been formulated as follows:
“Your Tunisian friends have many questions about sexuality:
- Either they do not ask for several reasons.
- Or, they ask, but do not always find the answers to their questions.
If you want to help and inform your friends you will have the task of selecting and achieving, with or for them, two of the five following activities:

1. *Complete, with a survey, List A (List of “Questions about sexuality”) And give some answers,*
2. *Complete, with a survey, the List B (List of “Ideas about sexuality”: Quiz, answer true or false)*
3. *Show the different dimensions related to sexuality education and explain the importance of this education*
4. *Add questions or ideas to the lists A and B (This activity was done by all students)*
5. *Make a list of organizations and associations who can help with any difficulties or problems.*

For more details a web link inside this mission is given for pupil’s guidance. This guidance describes procedures and steps for a successful implementation of the mission and explains how to organize the information acquired.

2.3.2. WebQuest explanation of mission elements

***- List A** : Questions about sexuality*
The questionnaire is anonymous. It is very simple because it is formed by a single question. In this questionnaire, pupils are asked to submit their questions in relation to the theme of "human reproduction and sex education". Their responses could either be delivered to a group of pupils responsible for referencing or data collection or to their teachers, either directly deposited on a website, including a WebQuest and a wiki, specially designed for this purpose. It was stated that the results of their questionnaire responses could be viewed directly on the same website. *They can, also, give some answers to chosen questions.*

***List B** : List of "Ideas about sexuality":*
This list is used to reference or to test ideas or assertions concerning reproduction and human sexuality. To do this, pupils will specify, via a click, if these allegations are true or false. From their choices and their answers they can assess their position relative to some misconceptions, prejudices or stereotypes.

2.4. Treatment of wiki and WebQuest

2.4.1. Treatment of questionnaire data

All responses are filed on a website, a wiki site "didaquest.org", in the List A *"Questions about sexuality"*. The questions raised by pupils are treated according to a classification grid and according to criteria explanatory (2.4.1.1. & 2.4.1.2).

2.4.1.1. Grid classification of pupils' questions

The pupils' questions were grouped according to the following dimensions: Biology; Sexual and reproductive health; Psycho-emotional; Socio-cultural (Table 3)

Table 3: Sample of grids for categorizing dimensions related to Human reproduction and sex education

Biology							
Anatomy	Physiology	Endocrinology	Neurology	Embryology	Genetic	Immunology	Ecology
Sexual and Reproductive Health							
Biomedical aspects	Promotional aspects	Individual aspects	Social aspects				
Psycho-emotional							
Individual	Relational	Fears and concerns	Addictions				
Socio-cultural							
Policy / Legislation	Economy	Culture / Customs / Myth	Religion	Ethics / Morality			

2.4.1.2. Criteria for clarification of pupils' questions

The explanation of pupils' questions by trainers should be made by one of the three following criteria:
- Explanation by direct responses
- Explanation to avoid confusion
- Explanation to avoid misconceptions (false conceptions)

2.4.2. Treatment of *"Ideas about sexuality"*

The purpose of the list B "Ideas about sexuality", about the misconceptions, prejudices or stereotypes is threefold. Firstly, it allows several statements to reference that can induce misconceptions. Secondly, it aims to encourage pupils to reflect upon the pertinence of their assertions, following the self-assessment (self-evaluation) of their responses (answer true or false). Finally, it is also possible to quantify pupils' responses and to deduce the number of misconceptions, prejudices or stereotypes. However, in this paper we only take into account the qualitative aspect, the first two points, emphasizing the impact of statements about pupils thinking.

2.4.3. Treatment of consulted pages

Even though this notion goes against Wikimedia privacy policy, in our wiki we have to analyze the user's activities relatively to particular pages. In this purpose we used 4 complementary statistics tools:

- **Mediawiki** Special: SpecialPages: This page contains a list of special pages. Most of the content of these pages is automatically generated. This page contains several statistics special links (Active users, list, User contributions, User group rights, Users, Recent changes and logs, Gallery of new files, New pages, Recent changes, Related changes, Media reports and uploads, Preference statistics, Statistics, System messages, High use pages, Most linked-to categories, Most linked-to files, Most linked-to pages, Pages with the most revisions). Examples of a statistics special page:
- **Mediawiki Special: Statistics:** a page, included in the mediawiki software, in special pages , that reports the current number of articles. Also recorded are the total number of pages overall, the number of edits and edits per page, and the number of registered users and administrators, along with links to other statistics pages.
- **Mediawiki Extension WhoIsWatching** (Version 0.9)**:** This extension provides an interface, at the bottom of every page, to see which of its users are watching particular

pages. Additionally, this extension has an option to allow any user to add any page to any other user's watch list.

- Mediawiki Extension: WhoIsWatchingTabbed (Version 1.3.1)
This extension create a tab "Who's watching this? (X)" where X is the number of users watching the page. When the tab is viewed it will display a grid of users who are watching the page. Each result will display the username, user real name, and page name. Usernames are linked to the same watching page, but will display all pages that the user is watching. Page names are linked to the same page, but will display all users watching that page. This installation will provide access only to administrator group. Viewing the special page will display top watching users and top watched pages defaulted to 10 each but with ability to raise that limit.
- **AWStats** (Version **6.95**): This statistic tool is a free software distributed under the GNU General Public License. AWStats is a powerful and featureful tool that generates advanced web, streaming, ftp or mail server statistics, graphically. This log analyzer works as a CGI or from command line and shows all possible information, in few graphical web pages. It uses a partial information file to be able to process large log files, often and quickly. A log analysis enables AWStats to show the following information:

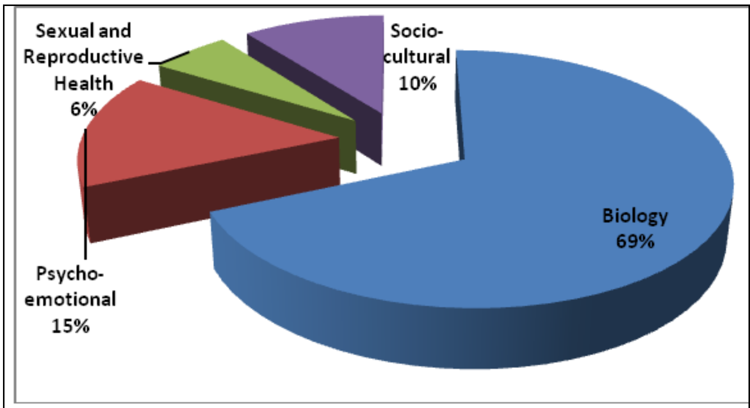
- Number of visits, and number of unique visitors,
- Visits duration and last visits,
- Authenticated users, and last authenticated visits,
- Days of week and rush hours (pages, hits, KB for each hour and day of week),
- Domains/countries of hosts visitors (pages, hits, KB, 269 domains/countries detected, geolocalisation detection),
- Hosts list, last visits and unresolved IP addresses list,
- Most viewed, entry and exit pages,
- Files type,
- Search engines, key phrases and keywords used to find the site or contents about this site (The 115 most famous search engines are detected like Yahoo, Google, Altavista, etc...),
- Number of times the site is "added to favourites bookmarks".
- Other personalized reports based on URL to analyze particular pages, keywords, categories,..

To facilitate the reading of the results, we only present in this communication, the statistics for the categories of the most visited sections, between March 2009 and May 2010 (Rank, Article, page views).

3. RESULTS

The following figures and tables show, following the mission assigned by the WebQuest, the impact on production activities and pupils website consultations:

It is important to note that several dimensions could be treated and viewed by pupils (Figure 1 and 2) .



Human reproduction and sexuality Aspects	**Page views on this website**
Biology	*24166082*
Psycho-emotional	*5325551*
Sexual and Reproductive Health	*2058586*
Socio-cultural	*3683232*

Figure 1: Graphical representation of wiki consultation pages related to reproduction and sexuality (Cumulative website consultation by Ip, between March 2009 and May 2010).

All dimensions have been consulted extensively with a minimum of 250,000 consultations. In these consultations:

- A great importance is given to biological aspects, particularly in anatomy and physiology (Figure 2).
- The dimension on health, although the least consulted, allows pupils to reflect on the dimensions of biomedical problems, while emphasizing the aspects relating to health promotion.
- The psychological dimension is viewed significantly, especially the aspects of "fears and concerns" and the relational dimension.
- The socio-cultural aspects show that pupils are both interested in issues relating to laws but also to religion and ethics. The relative "Cultural / Customs / Myth" aspects are the most consulted, which could contribute to destabilize certain prejudices or misconceptions.

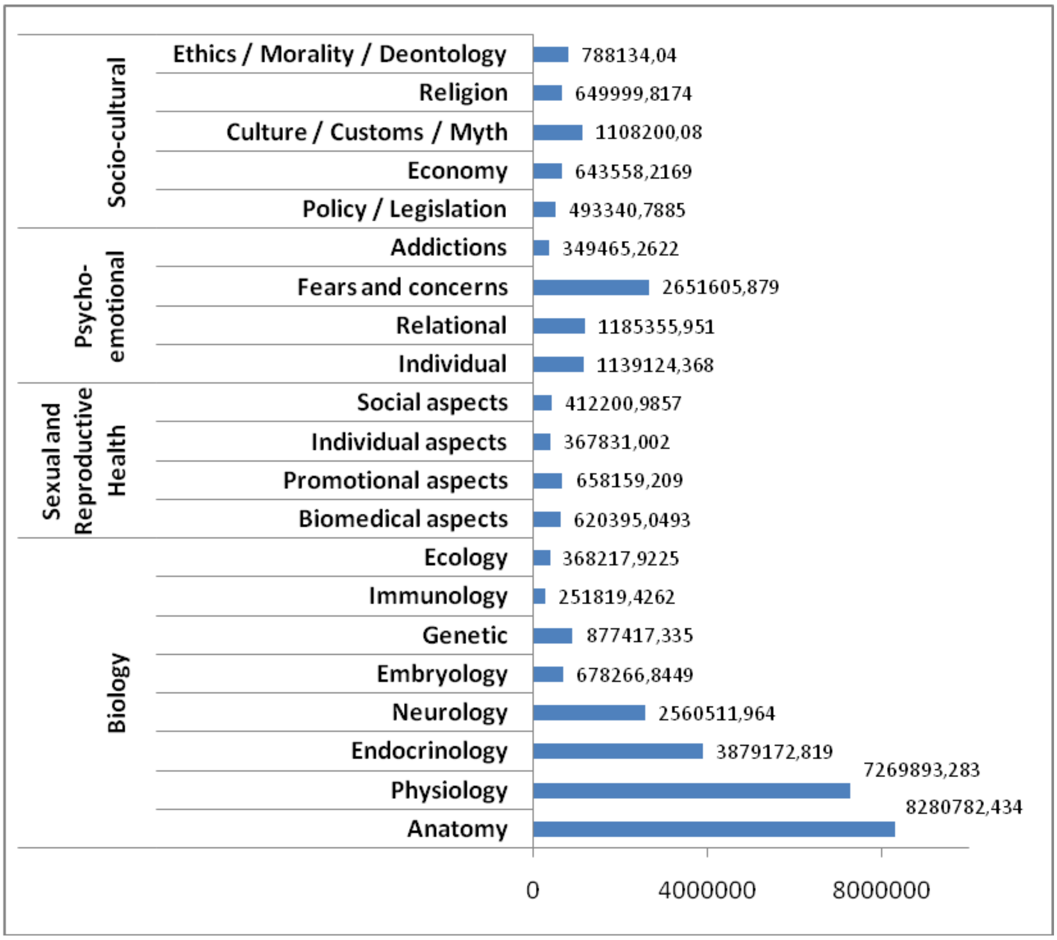


Figure 2: Details of graphical representation of wiki consultation pages related to reproduction and sexuality (Cumulative website consultation by Ip, between March 2009 and May 2010).

Figure 3 clarifies the expectations of pupils. Virginity seems to be a major concern and the hymen occupies a privileged position. This aspect reflects the influence of social and cultural context Arab-Muslim. It is important to note that expectations concerning sexual life and concerns about birth control are also important and they go beyond the scientific concerns related directly to the genitals and their schedules. It is also important to note that feminine components are most viewed.

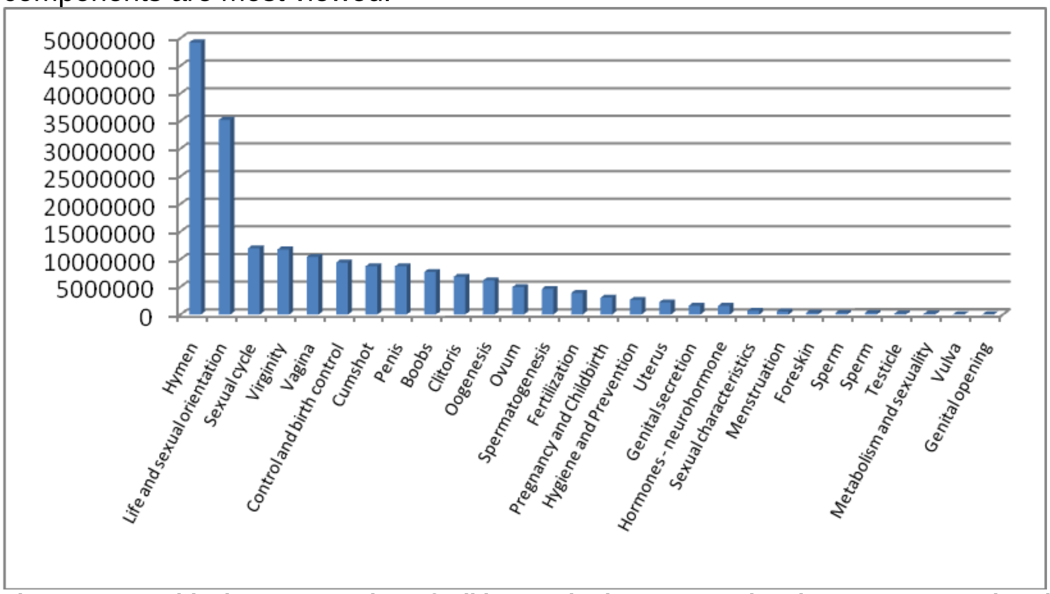

Figure 3 : Graphical representation of wiki consultation pages related to concepts and notions of human reproduction and sexuality. (Cumulative website consultation by Ip, between March 2009 and May 2010).

The section related to “Questions” (List A) and those related to misconceptions (List B) are very informative. Over 1,500 questions were asked (see website Didaquest.org). The results of Figure 4 show the importance of consultation of the questions of pupils and more significantly the importance of interface “true / false questions” (self-evaluation)

<table>
<tr><th>Human reproduction and sexuality viewed activities</th><th colspan="2">Page views on this website</th></tr>
<tr><td rowspan="2"></td><td>Asked and formulated Questions (more than 1500 questions asked)</td><td>181436</td></tr>
<tr><td>True / False Questions</td><td>1005172</td></tr>
</table>

Figure 4: Graphical consultation activities "Asked Questions" and "True / False questions. (Cumulative website consultation by Ip, between March 2009 and May 2010).

In the light of expectations and pupils' activities, the pupils and the educators (teachers, inspectors) have been important in structuring expectations and categorizating and explaining questions and ideas. The interests of different stakeholders are summarized in Table 4.

Table 4: Examples of interests of different actors (pupils and educators)

<table>
<tr><td>Inspector’s Participation - This participation has been important in connection with the following:</td></tr>
<tr><td>• Formulation of program from questions and needs of adolescents
• Development of educational strategies on one or more dimensions and proposed activities for the classroom, health clubs or for non-formal educational settings (some techniques: anonymous questions, Metaplan (sticky), group discussion, Brainstorming (brainstorming), variants of the Abacus Regnier, variants of Chinese portrait, burdock (Bardane), photolanguage (photo-expression), ICT (Wiki, WebQuest, simulations, ...)
• Evaluation of contents, documents and websites offered
• Specification of objectives and skills that can be mobilized
• Recommendations for teachers and stakeholders</td></tr>
<tr><td>Teacher Participation - This participation has been important in connection with the following:</td></tr>
<tr><td>• Management of pupils activities (production, debates, ...)
• Mobilization of objectives and skills (see skills list in website)
• Restatement questions of students
• Assess the students' productions
• Consolidation of questions and expectations of students
• Identification of concepts and their grouping
• Enrichment of content, documents and web links
• Followed the development of contents with high expectations
• Development raises questions
• The pupil guidance in taking into account the different biological aspects, and psycho-social issues related to reproduction and sex education.
• Help pupils in the construction of arguments to pass from opinion to thought</td></tr>
<tr><td>Pupil participation - This participation has been important in connection with the following:</td></tr>
<tr><td>• Investigation into the WebQuest (for pupils in health clubs) through the activities and investigations, particularly
- The collection of questions of their fellows
- Reformulation of questions in the form of misconception, or affirmation (correct or not).
• Formulation of expectations through asked questions
• Self-evaluation of their responses regarding their views and more particularly to certain prejudices
• Position in the discussion of “controversial issues”
• Dissemination of the site (autonomously and independently of applications for teachers)</td></tr>
</table>

The strategy used, in conjunction with pupils' expectations, has resulted in the following outcomes:
For pupils -

- To collect a large number of pupils' questions by raising or inhibiting certain taboos
- To identify the interests of pupils, according to two complementary indicators (dimensions classification issues, and frequency of consultation pages).
- To specify explicitly some confusion and pupils' conceptions (misconceptions, prejudices or stereotypes)
- To enrich scientific knowledge of the reproductive system, while developing an approach to health promotion and sex education in its broadest sense.

For educators -

- To provide tools for teachers to provide training, or additional training.
- In coordination with the pupils' activities and results of their products it was possible to optimize the wiki, taking into account the frequency of consultations on dimensions related to sexuality and the referencing of questions and misconceptions.

4. CONCLUSION

Learning effectiveness depends on a large range of parameters. A learner's activity has an important impact on long-term learning and comprehension of difficult concepts (Wilson & Lowry, 2001). Collaboration is also an important parameter for learning efficiency. Collaboration does not work *per se* (Dillenbourg**,** 1999); an appropriate strategy is a key factor for succeeding. This communication describes approaches to improve collaborative learning by presenting how the complementarities of an appropriate WebQuest and a wiki can facilitated learning and teaching of human reproduction and sex education. Combining those two strategies seems to be a powerful tool for constructivist learning environments because it not only facilitates collaboration but also shows how to deal with themes that raise multidimensional questions about scientific, social aspects including taboos. Additionally, this research shows educators how to use digital tools, such as WebQuest and Wikis, in order to create relevant, interactive learning experiences. Finally, this strategy is an example of a teaching strategy that shows how pupils, teachers, inspectors and didacticians can interact in complementary fashion.

1. INTRODUCTION

Traditionally, female are more distant from science then male ones and from the choice of scientific training, in particular in the area of mathematics and physics. Indeed, even today, in all European countries, the educational choices of students reflect a persistent heterogeneity in terms of gender: among the science faculties, while female are more frequently enrolled in medicine, biology, biomedical engineering and mathematics to address educational, the male enrol more often in physics, computer science, mechanical engineering and pure and applied mathematics. Despite an overall growth in numbers of girls in scientific fields over the last thirty years, it is still continuing the so-called "Leaky Pipe phenomenon" (literally, conducted leaky), showing the progressive loss of potential women to high levels of education and careers and technology. This happens despite female students are to graduate sooner and better than their peers, even in science faculties, as documented in various national and international surveys (EC 2009a). The data relating to 2006 show a difference in this regard since 31% of women in degree programs in science and engineering up to 11% of professors at the highest level of scientific responsibility. This difference clearly indicates the gap between men and women even though the comparison between 2002 and 2006 indicates a slight improvement on the status of female (EC 2009b)

Table 1. Proportion of men and women in a typical academic career (Science and Engineer). Students and academic staff. (EU 27) 2002/2006

	% female 2006	% male 2006	% female 2002	% male 2002

Grade B	22	78	17	83
Grade A	11	89	8	92

Source: European Commission, *She Figures 2009. Statistics and Indicators on Gender Equality in Science*, Luxembourg, Pubblications Office of the European Union, 2009.

In recent years, this phenomenon (a relevant gap in the female training and scientific career) in some way is beginning to affect even the male. There is indeed a comprehensive "scientific vocations crisis" which is shared by students, especially in the fall enrolment in courses to undergraduate physics and mathematics area. At the same time, in the case of male, there is not only an increasing orientation towards the humanities (a typical female orientation), but also a greater interest towards the technical application, unlike female who are still nowadays more interested in the environment and health (EC 2009b).

What contributes to this diverse attitude of students towards science? To answer this question, we must investigate what is the students' imaginary around science in the contemporary world, and the interest that both appear towards science subjects at school and to the scientific career paths to try to understand, finally, what influences their choice of university studies (Arzenton, Nechifor, Pellegrini 2008).

The survey conducted within the ROSE1 project has helped to provide some elements of the social representation of science expressed by boys and girls of 15 years, providing certain assumptions underpinning this diverse male and female attitudes toward science, science subjects and training and scientific careers. In particular, through Rose, it has been possible to identify certain types able to outline the main differences between boys and girls with respect to science in general and science at school in particular.

The research took into account three variables: geographical area, type of school, gender differences. Among these, the gender difference has been the most significant. For this reason we chose to focus on this variable. The survey involved 1445 students attending the second year of high school. We tried to select a homogeneous group of students composed of gender and the kind of study: 53.6% of students are girls, while boys are 46.4%.

The main areas investigated by the research has been:
- the students' interest about science and scientific topics;
- their opinions on science and technology;
- images of science and technology created into the school context;
- the experiences related to science and technology in the school context.

2. METHODS

The Italian wave of ROSE survey was conducted through an interpretative approach oriented to highlight primarily what would emerge from the data. The adoption of this methodology has allowed the development of an analysis able to exploit the environment to the sample, rather than theories or models of interpretation developed by the Public Understanding Studies of Science, the movement of researchers and experts of communication built up from the '70s to give to the public the tools for understanding the science and to teach literacy in different scientific subjects.

It is an approach midway between a quantitative and qualitative study: the theory must be developed from data in order to remain faithful to the data, trying to develop classifications and categories that integrate and explain the data.

This approach is particularly important where you intend to develop a gender analysis because it can leave aside "gender blind" theories, so called "gender neutral" theories, and thus leave room for assumptions and arguments that have a contextual significance. On gender approaches' "contextualism", a vast literature in feminist epistemology is available,

1ROSE: the Relevance of Science Education is an international comparative research project meant to shed light on factors of importance to the learning of science and technology (S&T) – as perceived by the learners, specifically by students towards the end of secondary school (age 15). http://www.ils.uio.no/english/rose/index.html.

that, for reasons of space, we are not going to deepen here. At very large sum, several feminist epistemologies are developed from a shared assumption: the subject of knowledge is not an abstract subject, neutral and universal, but a concrete, embodied, gendered and partial subject. Also the contexts we want to know are not a neutral, but they have systematically a gender dimension that reveals the symbolic and material relations between female and male, and between women and men. For this reason, any theory of knowledge, and any survey taking gender into account, can not develop from abstract theoretical models, neutral and universal, but necessary items from data, quantitative and qualitative, disaggregated by gender, and related to specific contexts under investigation, in which men and women relate2.

3. MAIN RESULTS

Despite the overall decline in enrolments in science, engineering documented in various sources, both domestic and international (Vesentini 1994; Anisn 2003; Eurobarometer 2008), the research showed a high level of trust of students in scientific research, particularly in relation to its contribution to the overall improvement of life. This positive attitude emerged in previous surveys on youth: in those carried out by IARD all of the respondents believe that scientific research has a vital role in ensuring high quality of life, the most recent Eurobarometer detected among Italians levels of trust in science even above the European average. (Eurobarometer 2008)

At the same time, the study of science subjects at school is unattractive and difficult, although its importance is not underestimated. So also is little attraction to the opportunity to pursue a career in research science and technology.

The low attractiveness of the scientific profession may be at least partly explained by comparing the occupational aspirations of new generations with the image of the work of the scientist is more widespread: a work full of creative opportunities and expression of individual qualities but also a work which requires a dedication and an investment so strong as to become almost all-encompassing, imposing the renunciation of the possibility to find satisfaction in other areas of life. Not only the image of the work of the scientist, but also the large image of science is not very positive. Indeed, while there is a high trust in science, particularly in relation to its contribution to the overall improvement of quality of life, the figure of the scientist does not collect, by contrast, extremely positive. This finding introduces a discontinuity with the past, even recently, when on the contrary, scientists enjoyed great credibility and could count on widespread image of neutrality and objectivity.

Moreover, it highlights an apparent contradiction between the lack of willingness to deepen their scientific inclination and the wide use of technologies (mobile phone and computer) widely found in extra-school environment. Although this is only a seeming contradiction considering that the skills required for the use of technological objects, even the most complicated, do not include the knowledge of scientific principles, the different issues addressed by the ROSE research, to which male and female students show greater interest (health, possible risks arising from technological development, sexually transmitted diseases, issues of energy and those relating to environmental protection) largely refer to applied dimension of scientific knowledge.

2 For a discussion of the contextualism in feminist epistemology, see for example: Alcoff and Potter, 1993; Harding and Hintikka, 1983; Harding, 1986; 1991; Longino, 1990; Vassallo, 2003.

4. ATTITUDE TOWARD SCIENCE AND ACHIEVEMENT MOTIVATION PROFILES OF MALE AND FEMALE

Starting from the analysis of data collected, we identified the following profiles: the omnivore, the disinterested, the environmentalist, the healthful. For each of these profiles we set out the most significant characteristics in relation to: overall interest to all the thematic areas proposed in the survey, further work on environmental issues, science at school and confidence in scientific research.

1) The omnivorous: is a student who tends to be more interested than the average in any thematic area concerned. In relation to future work this student shows a strong propensity for creativity and independence, suggesting self-realization in work. He's the most involved into environmental problems, a feature which contrasts both with healthful and environmentalist profiles (which are very similar to each other), and even more with the disinterested one. He is also the most attracted to science at school: his level of perception of the importance of science is well above average in general, with less difficulty dealing with the study. Finally, he shows the highest level of confidence in all areas of scientific research (confidence in the benefits of science, faith in science in favour of poor countries, confidence in scientists);

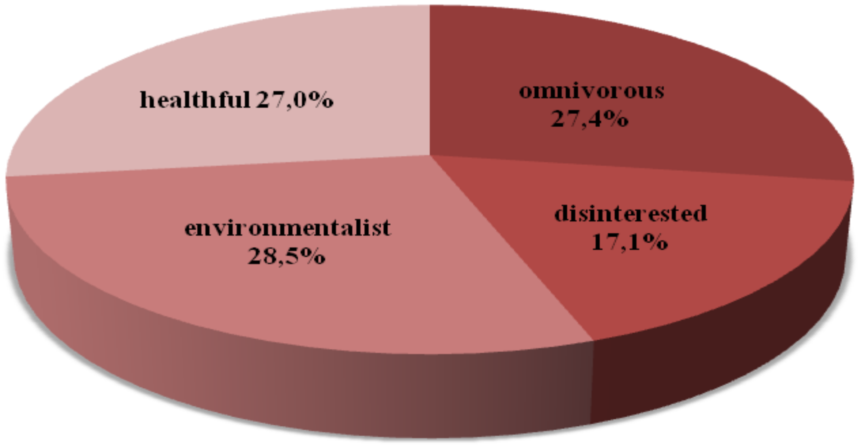
2) The disinterested: completely opposite to the first type he is characterized by higher levels of interest in the overall average in all areas. In relation to future work he is attentive to the dimensions of independence and time for himself, and also with the biggest attraction for the fame and success, but with the least sensibility towards environmental issues. He shows the whole less confidence in scientific research, especially in regard to the potential benefits of science;

3) The environmentalist: in general this is a student who expresses interest levels on average, but above the overall average in relation to all the factors concerning application of science and technology, especially in the case of environmental issues. In relation to future job he has the highest level of manual orientation. Regarding the faith in science, this profile is similar to the omnivorous, but with lower levels of trust;

4) The healthful: while bringing out a special interest in body care, for the most spectacular natural phenomena and the paranormal, students who are in this profile express some level of interest below average, particularly regarding issues related to applied aspects of scientific research. In relation to future job this profile shows importance of creativity and independence, greater propensity to have time for himself and greater rejection of handedness. As for confidence in science shows a peculiar behaviour: his faith in science is high enough, combined with a level of confidence in the ability to solve the problems of poor countries equal to the disinterested. Regarding trust in scientists and environmentalists the difference is not statistically significant.

The profile of which is the most part of students is the environmentalist, which collects 28,5% of the sample. The healthful profile is up to to 27%, while the disinterested reduces to 17% of the sample. It follows that most of the students interviewed are very or fairly interested in science and technology, albeit with considerable fluctuations.

Figure 1. Percentage distribution of 4 students' profiles



Regarding the gender distribution, among the omnivorous there is a greater presence of females, while the disinterested are distributed almost equally between males and females, although boys generally are more disinterested than the average. As omnivores even among health-conscious girls were found to be prevalent. The boys, however, contribute more of their contemporaries to the formation of the group of environmentalists.

Table 2. Students' profiles and main features

Profile	Gender distribution	Interest in science	Future work	Enviromental issue	Science at school	Trust in science
Omnivorous	Prevalence of girls	Most interested	Creativity, indipendence and realisation by themself	Greater involvement	The most attracted to scientific subjects, less difficult to study	Increased confidence in science
Disinterested	Boys and girls	Uninterested	Independence, time for themselves, fame, success	Lower sensitivity	Not attracted	The whole less confidence in scientific research, especially in its potential benefits
Enviromentalist	Prevalence of boys	Interest on average; greater interest in applications	Strong tendency in hand labour capacity	More involvement in the applications of science in the field of environmental issues	Interest on average	Similar to omnivorous profile, but with lower level of trust
Healthful	Prevalence of girls	Diversified interests, greater interest in body care and natural phenomena	Creativity, independence, greater vocation to take time for themselves, the greatest rejection for hand labour	Level of involvement below average, most of all in the application of science	Less attracted to scientific subjects, more difficult to study	Faith in science high enough, level of confidence in its benefits for poor countries similar to the disinterest

5. SIGNIFICANT FEATURES FROM A GENDER PERSPECTIVE

One of the most significant issue emerging from the types of profiles is the strong interest in the practical application of science that characterizes the prevailing profile in the sample, the "environmentalist" one. This prevalence of interest in the concrete application of science suggests some commonality of female and male students with current changes in science, which tend to undermine the classical distinction between pure science and applied science, helping to set up science as technoscience. Indeed, at present, not only technological objects pervade our daily lives - and these objects are "full of science" - but also the same scientific practice in several ways, in turn, tends to depend on the accumulation of data that technologies widely provide. Consider for instance the fact that in many areas of scientific research science depends substantially from the practices of virtual simulation.

Despite an overall proximity of students to these changes that affect science and society in our present, this high techno-scientific orientation concerns mainly boys and not girls, since boys and not girls are more present in the environmentalist profile, suggesting that the traditional male association to science is not exceeded, but only reconfigured into a new techno-scientific frame.

Less present in the "environmentalist" profile, girls are more present in the "healthful" profile, where they show a strong interest in body dimension and natural phenomena. This more female orientation towards aspects of life, that in the ROSE research is further confirmed by the prevalence of interest in life sciences (medicine first) among girls, tends to polarize with respect to the technical/technology orientation prevailing in the environmentalist majority male profile, suggesting another way of looking at science: connecting with and relating to the “self body” and nature, rather then manipulating and instrumental transforming objects of knowledge (techno science as manipulation and transformation of organic and inorganic environment).

Also the emerging interest in paranormal phenomena in this profile can be considered an additional element that tends to undermine the traditional boundaries between scientific and unscientific, in conflict with a traditional idea of scientific knowledge: a knowledge that requires a strong separation between the self (self as body) and the object of knowledge (objectivity). In other words: a scientific knowledge not influenced by subjective/emotional/body elements

In summary, from a gender perspective, the "environmentalist" profile (male-dominated) can be interpreted in alternative or in opposition to the profile "healthful" (a female predominant).

The minority of girls in the "environmentalist" profile and, conversely, their prevalence in the "healthful" profile can also be associated with their prevalence in the "omnivorous" profile. This profile indicates a female interest in non-instrumental knowledge, in a knowledge more based on the passion of knowing, and also a greater involvement of social aspects. This confirms the fact that in environmental issues, one of the topics on which research has investigated more, girls have a level of involvement more pronounced. ROSE research has also shown that humanities high school students are the most aware and involved in the environmental issue.

Another important finding from a gender perspective concerns the perception of difficulties in learning science at school among boys and girls. As it has been already noted, science at school is unattractive, it is also difficult to study, although its importance is not underestimated. In this general frame, boys seem better disposed towards science at school. Several aspects can be considered from a gender point of view: firstly, the teaching relationship as vehicles of conscious or unconscious gender stereotypes, secondly and even more, the styles of teaching science, often still attached to the concept of “innate attitude” in learning science that particularly penalize girls. This concept has a particular importance in the historical-philosophical evolution of epistemic categories internal to science, that have helped to exclude women from the history of scientific thought. The fact that they continue to be central in the educational practices of science subjects at school suggests that there are remnants of a past that tends to penalize the female gender in science education. In other words, scientific intuition, innate predisposition to learning science, [it] is still rewarding in evaluations by the school and teachers and is considered male dominated, contributing to the early formation of traditional gender stereotypes starting from the primary school and having an effect on the distance of girls from science (see, for example, Allegrini, 2009).

6. CONCLUSIONS. GENDER AND SCIENCE: BETWEEN TRADITION AND CHANGE

The diverse male and female attitude towards science documented by ROSE shows both elements of discontinuity and continuity in relation to the traditional configuration of the relation between gender and science: male “hard” sciences – female “soft” sciences. Within a large feminization process that in the last forty years involves different fields of knowledge and work, girls are more and more present in traditionally male areas of knowledge and work, such as the scientific field. This feminization represents a discontinuity's element, that happens by turns with an other continuity factor with the past: compare to the same age boys, girls are less attractive to technology-application oriented science, while appear to be much more interested in social and natural aspects of science. Indeed, in ROSE research, girls are not only more involved in social dimension of science, but also in environmental issues and in life sciences.

Not only in the case of girls, but also in the case of boys it's possible to observe an alternate of tradition and change. On one side, within the current process of science's transformation, in which science appears to be more tightly connected with technological research (techno-science), boys, and not girls, show a great interest towards apply science. On the other hand, boys are also approaching traditionally female training paths, such as human sciences, contributing to a comprehensive "scientific vocations crisis", especially in the fall enrollment in courses to undergraduate physics and mathematics area.

From a gender point of view, the persistence of a continuity trend with the past in boys and girls' training and careers paths suggests that, even if within a growing feminization process and science's transformation process, the traditional gender division among “male-hard sciences and female-soft sciences” is not overcame, but only re-configured in relation to historical and cultural change.

Still, discontinuity's aspects might be interpreted in relation to a overall crisis of the dominant role “classic-positivist” scientific ratio traditionally plays. This is why “scientific vocations crisis” especially involve those western countries which carry on the highest economical investment in science and technology. In other countries, such as Italy, whereas tradition and change still meet together, some traces of archaic culture tend to persist together with a more traditional representation of gender and science. Furthermore, in these countries, there is also the highest level of trust towards science. Indeed, compared to other European students, Italian male and female students show a highest level of trust in science, most of all in its contribution to improving the quality of life, although they also show a discontinuity in the representations of scientist, who is invested of less credibility and authority.

STUDENT PARTICIPATION AND MOTIVE DEVELOPMENT IN SCHOOL SCIENCE: THE CASE OF HELENA'S MISTAKEN ACID

Maria Andrée

Dept. of Mathematics and Science Education, Stockholm University

Maria.andree@mnd.su.se

ABSTRACT

Previous research on science education has described various factors influencing students' participation and produced categorizations of students based on e.g. cultural background. In this article it is argued, theoretically and empirically, that an understanding of students' participation in science education needs to begin with an analysis of what activity students are engaged in. The aim is to shed light on student participation in science classroom practice and how altered conditions of classroom practice can make additional space for developing motives for learning science. Activity is conceptualized in a cultural-historical activity theoretical perspective as what transformation of objects students are engaged in. Drawing on an ethnographic study in a Swedish compulsory school, a critical incident of the participation in science education of a 7th grade girl called Helena is analyzed. The results show that altered conditions of classroom practice may produce new possibilities for student participation, and point to the impossibility of determining students as 'different kinds of students' based on *a priori* categories.

Keywords: *participation, motive development, science learning activity, CHAT*

INTRODUCTION

When I participated as an observer in 6th and 7th grade science classes in a Swedish municipal compulsory school, I overheard comments such as "I hate natural science subjects," "Hate Science!", "I'm no good at natural science subjects" or "I won't get a pass". But there are also students talking about themselves as "fat scientists" and "researchers". For some students participation in school science appeared to lack personal meaning, whereas for others participation in school science appeared meaningful beyond the actual classroom task and significant in relation to a comprehensive development of identity.

Previous research on science education has described various factors influencing students' participation and learning outcomes in science education such as ethnicity, language, culture and socioeconomic status (Lee & Luykx, 2007). In Sweden, analyses made by the Swedish National Agency for Education (2009) show statistical relationship between parents 'educational level and students' school performance on achievement scores. Students' participation in science education has also been conceptualized in terms of border-crossings between different cultures (Cobern & Aikenhead, 1998). Costa (1995) described a model for understanding how students' responses to science are related to the degree of congruency between their worlds of family, friends, school, and science. Costa identified groups of students with different cultural backgrounds and labelled them Potential Scientists, Other Smart Kids, "I do not know" students, Inside Outsiders and Outsiders. Cobern and Aikenhead (1998) then described students' border-crossings between cultures of family, peers, school and science as smooth, manageable, hazardous or virtually impossible. The categorizations are based on an understanding of a student as an individual representative of particular cultures that are in conflict or consistent with school and science culture. With these categories particular identities are ascribed to individual students, in relation to Science, with reference to practices outside the science classroom (also Science is understood as singular and simplistically represented by school science cf. van Eijck, 2007). Consequently, the categories imply an individualistic static perspective on the student. Critique against this kind of research, from a Cultural-Historical Activity Theoretical (CHAT) perspective, emphasize that identity is a complex matter and that an analysis of student identity in relation to one specific practice results in a very abstract, unrealistic story (Williams, Davies & Black, 2007).

In this paper, I argue that students' participation in science classroom practice cannot be properly understood with reference to cultures outside of school practice. Instead, we need to take our starting point in the activities students' are participating in. The aim is to shed light on student participation in science classroom practice and how altered conditions of science classroom practice can make additional space for science learning and developing motives for science learning.

LEARNING, PARTICIPATION AND MOTIVE DEVELOPMENT

In CHAT human activity is understood as a system of relations in which societal needs are central. A constituting characteristic of activity is objectivity i.e. the object which is purposefully transformed (Leont'ev, 1977/1986; cf. Roth et.al., 2005). Education is a specific form of human activity, embodied in school practice, where teachers and students collectively undertake actions of making school 'school'. The question of what activity students engage in within school practice is an empirical question concerning what transformation of objects students are engaged in.

CHAT builds upon a dialectic relation between agency and structure, which means that agency and structure mutually presuppose and constitute one another (Roth, 2007). Most researchers who draw on CHAT focus on its structural aspects as developed by Engeström (e.g. 1999; 2001) in his triangular model of human activity systems. But a structural perspective on activity systems does not allow us to theorize individual learning or personality formation adequately (op cit). In this paper, I focus on students' development of motives for participation in activity, mainly drawing on the works of Leont'ev (1977/1986), Lomov (1981) and Hedegaard (1999).

Incorporation into any new community or collective give rise to new motives for activity and transforms the already formed motives of the individual (Lomov, 1981). Motives are developed through collective cultural practice and simultaneously related to a person's goals and characterize the person's activities. At a general level, educational content can be understood in terms of what educational motives are being realized in classroom practice (cf. Chaiklin, 2001). The objective of science education can be described as transformation of children, i.e. developing students' motives for participation in science-related activities (Chaiklin, 1999, 2001; Hedegaard, 1988). For teachers to develop learning motives for some subject matter learning they need to bring the student into situations where the activities acquire personal meaning, so that the student acquires a motive to enter into these kinds of activities (Hedegaard, 1999).

Previous research show that different students, superficially part of a common practice, may be engaged in activities corresponding to different motives (cf. Andrée, 2007; Hasse, 2002). In Swedish lower secondary school science practice, students are shown to participate in two different kinds of actions: *production and reproduction of correct answers*, corresponding to a motive of formal qualification, and *development of conceptual relations*, corresponding to a motive of science learning and enculturation into science communities (Andrée, 2007). In education aspects of personality is produced through the social relations constituted between students, students and teachers and between students and cultural resources of educational practice. A result of students' participation in different activities is that students are formed differently in relation to science. Consequently, science classrooms are not only places for learning science subject matter but also places where identities are developed through students' engagement in activity (cf. Kelly & Sezen, 2010).

FIELDWORK

This study was part of a larger ethnographic study. In pursuing an ethnographic line of research I attempt to account for particular cultural historical processes as practiced by particular people in a particular setting (cf. Wolcott, 1999 p. 253).

I have conducted ethnographic fieldwork in two science classes, grade six and seven, in a Swedish midsized compulsory public school during one school year. The school is situated in a socioeconomically and ethnically mixed city district. The two science classes are taught by Ann. Ann is in her mid thirties, holds a Bachelor of Science and Mathematics education, and has taught science for 3 years. A variety of data, from a broad range of classroom activities, was collected through participant observation; including field notes, audiotape recordings, formal and informal interviews, teaching materials, and some student work. Based on a preliminary analysis of field notes and transcribed interviews some of the audiotape recordings were chosen for verbatim transcription and detailed analysis.

In this paper, I analyze the work of Helena during a practical lesson in seventh grade science class. Helena works together with two other girls: Lisa and Jessica. The girls are usually engaged in production and reproduction of correct answers as part of an educational activity and their work can be characterized in terms of social positioning at odds with school science. The particular lesson is chosen as it involves a critical incident of an unexpected occurrence leading to a change of Helena's participation in classroom work. During the lesson the three girls use a 'wrong' acid and receive a green solution instead of a blue.

The tasks of the day are labelled: (I) "metallic oxide in acid" and (II) "metal in acid". In the first task students are instructed by the teacher to (1) dissolve cupper oxide in hydrochloric acid, (2) describe the process using chemical formulas and (3) formulate what salt they have produced. The teacher tells the students to write both the general and the specific formula of the salt produced in their conclusions in the laboratory report. The second task, which is only briefly mentioned in this article, is called "Metal in acid". Here, students are to dissolve zinc in sulfuric acid. The procedure is at large the same as in the first task. The intended educational content of the lesson can be summarized with the reaction formula which students are intended to write as conclusions in their laboratory reports (see table 1).

Table 1: Reaction formula to be written in laboratory reports

General: metallic oxide + acid → salt + water
Specific: cupper oxide + sulfuric acid → cupper sulfate + water
General: metal + acid → hydrogen + salt
Specific: zinc + hydrochloric acid → hydrogen + zinc chloride

THE CASE OF THE MISTAKEN ACID

Excerpt 1
I won't get a pass in Science […] I won't take N V or N A [short for science programs in upper secondary school]

The quote above is from Helena a couple of months prior to the lesson analyzed in this article. On another occasion, Helena talks to the tape recorder on the bench in front of her, used for my collection of data, about how boring Science is and much she hates Science.

Helena repeatedly marks her rejection of school science and positions herself at distance from work in the science classroom. In the laboratory task "Metal-oxide in acid", however, Helena engages in a discussion with the teacher and after having finished the laboratory task of the day she walks around the classroom, helping other groups of students to formulate conclusions. The critical incident was that the three girls used the 'wrong' acid and received a green solution instead of a blue. In the following, I give an account of the work of the three girls during the practical lesson on salt production.

Setting up the laboratory task

When the teacher finished her introduction to the laboratory task, Helena and her co-experimenters Jessica and Lisa retrieve the needed equipment. They assemble the Bunsen burner with tripod, lattice and cups. Helena goes to the front desk to fetch acid in a beaker. She brings the cup back to the bench and then all three girls go to look for the one jar of copper oxide which some other group had brought back to their work bench. The girls use a spoon to pour copper oxide into the acid. They are then supposed to heat the mixture in order to dissolve the copper oxide but Helena and Jessica begin to argue about who is to dare to ignite the Bunsen burner.

The procedure of igniting the Bunsen burner causes conflict and agony in the group: Who is to ignite the Bunsen burner? Who dares to? Helena and Jessica start fighting over who is to do it and the teacher step in as a mediator.

Excerpt 2

Lisa: hey, you can ignite it
Helena: no, I don't want to do that stupid crap
Jessica: no but hey don't do it
Lisa: now
Jessica: it's not to be turned on now
Lisa: yes
Jessica: no
Lisa: yes, now it is
Jessica: no but I don't want to, I don't want to
Helena: no but com'on (.) oh you're *chicken* [said in English]
Läraren: what's the problem girls?
Jessica: I don't dare to do that, I just dare to adjust that and then she calls me chicken(.) she doesn't even dare to do any of it
Läraren: try now Jessica
Jessica: I don't dare to (.) I don't wanna burn my hand
(matches are lightened)
Jessica: look there (.) I would have been scared to death
Helena: *super maan* [in English]

Helena calls Jessica chicken but also says that she doesn't want to "do that stupid crap". The Bunsen burner is circumscribed by fears for making dangerous mistakes, of being burnt and scared. After they've succeeded to ignite the Bunsen burner, Helena exclaims: "hate science!".

Getting a green solution

Lisa reads aloud from the instruction that they are to use diluted hydrochloric acid. Helena asks the teacher if "this acid here is diluted" and receives the answer that all acid is diluted. The girls then pour acid in a beaker. When the copper oxide begins to dissolve Jessica notices that the solution is turning green:

Excerpt 3

Jessica: Lisa, oh Lisa, it is green.
Helena: (inaudible) cause we did wrong
Lisa: why?

Jessica: it's supposed to turn blue
Helena: yes we used the wrong acid (inaudible)
Jessica: oh shit

Helena, Jessica and Lisa solved the copper oxide in hydrochloric acid, instead of in sulfuric acid. They note their 'mistake' when they get a green solution, unlike the other groups who receive a blue solution.

After having solved zinc in hydrochloric acid (i.e. task II) they set out to write results and conclusions in their laboratory reports. The girls call for the teacher for help. After a short discussion on their observations of how the color changed from black (the copper oxide powder) to green, Helena asks the teacher what the beaker contains:

Excerpt 4
Helena: what's that?
Teacher: ehm metallic oxide plus acid is salt plus (.) something (.) then you have one there that is metal plus acid is salt plus something
Helena: we did the acid first, so we're supposed to write that first or
Teacher: that doesn't matter
Helena: metallic oxide plus acid (.) what's that? [salt
Teacher: [yes that is what we wrote
Helena: salt
Teacher: yes salt plus what? that was what you had for homework til Friday
(Helena turns pages in her book)
Teacher: that there Helena, turn that (.) the blue one high up
[…]
Jessica: what's that called in there, the liquid (.) what is it after methods?
Teacher: then that was an acid (.) what acid did you use? you had hydrochloric acid
Helena: mm
Teacher: then that was hydrochloric acid and cupper oxide
Helena: yes, but it says water plus cupper sulfur
Teacher: but look at it (.) metallic oxide plus acid is some form of salt and water
Jessica: what salt will it be?
Teacher: well that depends on what you use for-
Helena: metallic oxide and hydrochloric acid
Teacher: yes then you get the metal and acid forming a salt that is called (.) it can't be called cupper sulphur because you don't have any suphur ions
Helena: no then you'll get
Teacher: then you'll get cupper and what's the ion of hydrochloric acid?
Helena: ehum that is an acid so it'll have to have hydroxide ions
Teacher: no then that is [a base but what about the other ion
Helena: [ehum ehum hydrogen ions
Teacher: hydrochloric acid contains hydrogen ions plus another ion
Helena: that I don't know
Teacher: yes, what does the formula look like
Helena: chlorine
Teacher: yes, and what is it called if you make an ion out of chlorine?
Helena: chloride
Teacher: then you'll get cupper chloride

Helena asked the teacher about what happened and the teacher suggests that they took the wrong acid (which Helena already concluded in excerpt 5). Helena continues to talk to the teacher about what salt they produced and she contributes with facts about which chemicals they have used and the composition of ions in hydrochloric acid. The fact that Helena and her co-experimenters got a green solution, instead of a blue, focuses her attention on the acid that they used hydrochloric acid instead of sulfuric acid and that the choice of acid was important. The teacher guides Helena through reasoning about what chemical reaction has occurred.

The green color also attracts attention from other students. Chandra, from a different group asks: “How did yours turn green? Helena how could your stuff here get green?” “Because we happened to put in the wrong acid”, Helena explains. Another student exclaims: “God, theirs is green”.

Hannah, who is said to be the most successful girl in science class by both other girls and the teacher, comes to discuss her conclusion with the teacher. Usually the other girls in class would try to copy Hannah’s conclusions but now Helena steps in to help Hannah:

> **Excerpt 5**
> Hannah: so, what should we write for conclusion?
> Teacher: the general formula plus the formula for the salt you made
> Helena: on which one are you? are you on this one?
> Hannah: no, I'm on this here blue one
> Helena: but look here, it says, metal plus acid and then you’re to write zinc plus hydrochloric acid

In excerpt 5 Helena displays confidence as a knowledgeable student in her interaction with Hannah. When Helena has finished writing the lab report, she walks around the classroom, explaining to other students why her group got a green solution instead of a blue, and also helping other groups to formulate conclusions in their laboratory reports. Helena does this, even though lab work practice allows students to leave for recess when they have finished their laboratory tasks and handed in their reports.

DISCUSSION

The case of the mistaken acid is an example of how altered conditions of classroom practice produce new possibilities for students’ participation in school science. Helena is usually engaged in an activity of science education i.e. she deals with the tasks given in order to produce what is needed for completion of the course which primarily corresponds to a motive of formal qualification (i.e. attaining a grade in school science and receiving a complete compulsory school diploma). She has also repeatedly positioned herself at odds with school science, e.g. in the beginning of the analyzed lesson in question when arguing with Lisa about the Bunsen burner.

The transformation of the laboratory task created conditions for a desire on Helena’s part to develop knowledge about the produced salt, in other words, conditions for development of motives for engaging in science learning activity were created. When Helena discovered that the solution became green instead of blue the lab work took an unexpected turn. The result is visible, surprising and requires an answer. Here, Helena, Jessica and Lisa produce a different salt than other students and the conclusions of other students cannot be used as ‘right answers’. What Helena, Jessica and Lisa have produced is no longer the planned pedagogical illustration of the general chemical process of salt production by dissolving metal oxides in acid. On one level, their work is in line with the intended educational content of the original task; as the choice of acid was subordinate to the illustration of the chemical process. From a teacher’s perspective, the task could just as well have involved hydrochloric acid as sulfuric acid. In school laboratory practice, however, the embodied task that the students work with is to solve the copper oxide in sulfuric acid. The laboratory task at hand was transformed from a routine task to a ‘real problem’. Helena and her group also produced something unique and different. We can compare the importance of clothing as an identity marker. In a school with school uniform dress code, clothing will not function as identity marker in the same way as in a school without uniforms. Similarly, school work with educational content is not something specific to particular students in everyday school practice when everyone is working with the same content.

Previous research on teaching science has described a number of factors relevant to our understanding of students' achievement and participation in the science classroom (cf. Cobern & Aikenhead, 1998; Costa, 1995; Lee & Luykx, 2007). What makes Helena's work exciting is that it demonstrates the impossibility of determining students as different kinds of students based on *a priori* characteristics. Based on information before the mistaken acid one might, using Costa's (1995) categorizations, have categorized Helena as an *"I-don't-know" student*, or possibly as *Other smart kids* – she positions herself at marked distance from, and in conflict with, school science and Science while engaging in work to produce and reproduce correct answers in order to receive a passing grade. What has changed in the case of the mistaken acid is not Helena's domestic conditions, but conditions for schoolwork. Characteristics such as socio-economic background, ethnic background or gender can always only partially account for development of motives for activity and identity. Categorization of different types of students may be a functional tool for categorizing students' work in the classroom, but it is not reasonable to make this type of categorization of individual students.

Students' participation cannot be determined in advance, but participation is always embedded in a particular practice. Biesta and Burbules (2003, p 111) write: "...the world in which we live is ever-changing and ever-evolving". This means that every situation we encounter is in some respect unique, albeit many of our actions are habitual and that the activity systems in which we engage both constrain and open up certain possibilities for action.

CONCLUDING REMARK

The mistaken acid becomes an example of how new conditions for participation in practice enable the activity of development of conceptual relations to acquire personal meaning a student. For Helena the mistake enabled her to engage in an activity of science learning. The educational challenge for science educators is to develop science classroom practices where all students will be provided opportunities to engage in science learning.

ABSTRACT

Ethics is the study of the moral basis of human behavior that aims to determine the best course of action. Bioethics, as a transdisciplinary area, based both on ethics and on life sciences, reflects upon the ethical problems raised by new technologies and scientific research. One of the main tools to tackle bioethical problems is deliberation, a procedure that attempts to analyse problems, weighing up the principles and values involved as well as the context of each case. Due to the complexity of deliberation, educational projects should be promoted, providing the practice necessary for correct deliberation and raising awareness of the current ethical issues.

It is our purpose to present a framework for ethical deliberation throughout the use of literature. Literary texts are essential, since they show human beings acting in space and time and they give the readers an opportunity to deliberate on ethical issues. Based on a literary text, we will reflect upon a controversial ethical issue - Preimplantion Genetic Diagnosis (PGD).

Keywords: *Bioethics, ethical deliberation, Literature, Preimplantation Genetic Diagnosis*

1. A MODEL FOR DELIBERATION

Ethics reflects upon human conduct *aiming at the good life with and for others, in just institutions* (Ricouer, P.,1992,p. 172). The issue we have to address is how we can decide the best way to act, choose the most prudent course of action, when we face conflicting principles/values as alternatives that exist precisely because we are free human beings. The imperative to decide and act is therefore inscribed in a context of free will, which is nonetheless determined by individual and social influences: 1) individual influences, such as age, character, natural talents, circumstances; 2) social influences, such as education and society. According to Aristotle, who taught deliberation as the main procedure of ethics, (moral) wisdom and (moral) knowledge originate from reflections on and within concrete situations, being thus impossible to separate moral truth from experience. Moral decisions, Aristotle further emphasized, are not a product of instrumental reasoning, calculation or logic, but flow from wise judgment, perceptiveness, imaginative understanding and an engagement with practice. In a nutshell, the meaning and construction of morality is inherently contextual and temporal.

Consequently, the first step to promote solid deliberation is to make individuals aware of the different factors that intervene in this process, of the different steps to be followed, and most importantly, of the situational nature of deliberative procedures. Moreover, one should also provide them with the opportunity to develop second-degree virtues, i.e. virtues that allow one to consider moral problems carefully and to act according to the results from the ethical reflection previously done. It is not enough to be compassionate, brave or benevolent (first-degree virtues), because when it comes to act, the second-degree virtues are the ones that make the bridge between the moral judgment and the intention to choose a course of action that respects this judgment. We think that this bridge can only be built by educating the future citizens who will have to decide upon controversial issues affecting their own lives and the lives of the next generations.

Different models have been designed to describe the ethical decision making process, being one of them by T.M. Jones (1991) – *An issue contingent model,* which is based on the idea that the moral intensity of a particular situation influences the way the individuals perceive that situation and the way they decide to act. There is thus a correlation between the moral intensity of a situation and the perception and ethical intention of the subject. In Jones' model moral intensity is defined according to six components: **magnitude of consequences**; **probability of effect**; **temporal immediacy; concentration of effect**; **proximity**; **social consensus**. A person's collective assessment of these characteristics results in a given situation's moral intensity. In general, issues with high moral intensity will be recognized as ethical dilemmas more often than those with low moral intensity, leading to a positive relationship between **moral intensity** and **perception** of an ethical problem. Furthermore, issues with high moral intensity have a positive relationship with an individual's **intention** to behave in an ethical manner. The fact that moral intensity is a key component in ethical decision making underlines the need previously mentioned of educating individuals on potential consequences and implications of ethical problems, so that their perception and decision making skills can be sharpened, when they encounter ethically sensitive situations. Other authors have proposed different models of ethical decision making, which share some items with Jones' model:

- Dawson W. Carlson et.al. (1997) have analyzed the impact of concentration of effect, probability of effect and proximity on the ethical decision making process and they added a variable that is not considered by Jones in his model – **Orientation.** This variable refers to the role played by the decision maker as the subject of the action, as an external advisor or as an element of an organization.
- Susan J. Harrington (1997) has also tested two of Jones's model steps (moral judgment and moral intent), by analyzing the strength of **social consensus** and of the **seriousness of consequences** on these steps. Moreover, the study goes further and examines different levels of social consensus and how they interact with important individual characteristics of **rule orientation** and **denial of responsibility** (how the former influences moral judgment and how the latter influences moral intent). Based on Jones' model, Harrington states that social consensus, i.e. the degree of social agreement that a proposed act is evil or good, influences ethical behavior: the stronger the social consensus against some unethical behavior is, the more likely it will act as instructions for behaviour. However, Harrington says that moral orientation and moral judgment do not give full explanation to moral behaviour, since this one is also related to moral intent – what the individual intends to do in an ethically controversial situation. Possible reasons for the gap between moral judgment and moral intent are: considering other personal values more important than the moral ones at stake; lack of recognition of an ethical issue or previous exposure to the issue, thus responding with less deliberate thinking; or neutralizing moral judgments by **denying responsibility (RD)** for the results. **RD** mediates between self standards

(moral orientation and moral judgment) and ethical behaviour: i.e. RD acts to neutralize self standards. Therefore we can say that whenever there is lack of social consensus against a particular type of behaviour, it will be more likely that those high in RD will agree with an unethical behaviour.

Jones' model (1991) as well as other models of ethical decision making (Gracia, D., 2003; Rest, J.R., 1984; Trevino, L. K., 1986; Vitel et. al., 1993) - see references to other models - usually include four basic stages: 1) **recognition** of the **moral issue**; 2) **moral judgment** about which course of action is morally right; 3) formation of a **moral intent**, that may not accomplish the moral judgment made before if this one collides with the individual's previous desires; 4) **moral behaviour**, which requires the motivation to act according to the moral intent.

2. BIOETHICS AND LITERATURE

Nowadays ethical decision making plays a key role in response to the dizzying advances in technology and the profound socio-political changes in a world caught up in globalization and multiculturalism. Therefore, it would appear to be of paramount importance that this new area of knowledge be properly disclosed and explained to civil society in order to seek their engagement. In fact, it is more and more important that students and society in general understand the need of well-reasoned judgments, combined with respect and empathy for other approaches.

It should go without saying that the transdisciplinary nature of bioethics demands different perspectives when dealing with ethical issues. These varied points of view are usually grouped under two kinds of approaches, mainly the *wide-range approach* and the *in-depth* one. The former is mainly related with the global and extensive view of ethical issues by responsible politicians, mass media, inter-disciplinary research groups and opinion makers; the latter is the basis of the research carried out by philosophers, religions and ethicists. Both approaches require educating the way we see the world, the way we speak about it, the way we reflect upon it and the way we act (hopefully) according to the steps taken before. Choosing the most prudent and the most appropriate course of action in a particular setting, with and for the others, considering not only the individuals directly affected by the decision, but also their community and the biosphere, was also the project outlined by Van Rensselaer Potter in his papers "Bioethics: the Science of Survival" (1970) and "Bioethics: Bridge to the future" (1971). Potter had a global perspective of Bioethics as a discipline that could set up the bridge between the ethical values of Humanities and the biological facts of Life Sciences, which he considered to be indispensable to guarantee the survival of Human Kind. Therefore, global bioethics is a concept coined by Potter, which he later included in the title of one of his works: "Global Bioethics: Building on the Leopold Legacy" (1988). Only by educating our sight can we fully understand the concept of global bioethics, focusing our reflection not only on the individuals, but also and most importantly on the Other that is part of each individuals' sense of their own identity. Moreover, education can provide citizens with the tools to participate in ethical deliberation on issues that concern not only the nature of scientific research and doctor/patient relationship, but also the survival of Human Kind with a human sense. Actually, these days Bioethics is considered by many experts as a civic ethics, i.e. as an ethics shared by the members of a community who see themselves as co-authors of the narrative of that society. According to M. C. Patrão Neves and W. Osswald (2000), the three main reasons for the current role of Bioethics as a civic ethics are: the lack of universal moral foundations, which can either lead to deep relativism or to the search for rules and guidelines applied to the particular setting under analysis; the Death of God, of the Author, of the unified subject, which has also led to the need of wide deliberation procedures, from different perspectives, that can be achieved by Bioethics due to its transdisciplinary nature; furthermore, the fact that Bioethics has been organized in institutions has also contributed to its functional role in our days. As applied ethics, Bioethics has a public dimension that has a strong impact on public opinion, providing the citizens with information and formation about the ethical issues underlying different areas of human action. The wide range of resources available in bioethics education provides different tools that can be explored according to the topic under discussion, the subjects participating in the ethical deliberation procedure and the kind of approach used to analyse the ethical issues. Choosing literary texts as a resource for Bioethics education means that this approach must be anthropological, bio-cultural, a revision of ethics as a dialogical search and not as a source of ready-made answers or recipes:

Today there are logocentric habits and an educational philophy focused on conveying information and training experts, which highlights the pragmatic and the scientific, the efficient and the instrumental dimensions of human life, but forgets the key role of imagination and memory. In fact,memory and imagination were the basis of a free, critical and creative thought of the greek civilization (Clavel, 2004, p. 77, our translation)

The metaphorical structure of literary texts – which implies a reading strategy of suspending the literal reference and locating the meaning between the world of the text and the text of the world – gives them the power to release a second-degree reference that provides the reader with the opportunity to see something in a certain way, thus shedding new light on the world and increasing human knowledge. Umberto Eco (2002) conceives of Literature as an enlightening source, which contributes to the building of language and cultural identity, while disclosing the vulnerable trait of humanity: literary texts reveal the impossibility of changing the course of their story, even if it is against the readers' will. Literature shows human beings acting in space and throughout time, making the readers aware of the limits and of the conditioning of their existence together with their freedom of choice. David Lodge (2009) adds to the ideas outlined by Eco that literary texts also express the uniqueness of each human being, since they are written in a singular and unrepeatable way, even when they recycle stories or import characters from other stories. It is this singularity together with a universal dimension that makes literary texts the place where experience can be deeply represented, making the reader see what characters tell, even when they tell it in the first person:

There is no ethically neutral narrative. Literature is a vast laboratory in which we experiment with estimations, evaluations, and judgments of approval and condemnation through which narrativity serves as a propaedeutic to ethics. (Ricoeur, P., 1992, p. 115)

It is important to notice, that the knowledge provided by literary texts will only be achieved through hermeneutics, i.e. through interpretation, which gives the reader an important role in this linguistic process rooted in the objective facts of the world and in the subjective interpretation of the individual who interprets them. It is precisely this hermeneutic process that sets up a bridge between narrative and identity:

By narrating a life of which I am not the author as to existence, I make myself its coauthor as to its meaning (…) It is precisely because of the elusive character of real life that we need the help of fiction *to organize life retrospectively, after the fact, prepared to take as provisional and open to revision any figure of emplotment borrowed from fiction or from history*. (Ibidem, p. 162)

2.1 The views of a novel

My Sister's Keeper, a novel by Jody Picoult (2004), makes us see this process of building identity through narratives told by the different characters that *attest* the Self that states *here is where I stand*, the Self that remains as time goes by, the Self that keeps the promise of being *Oneself as Another*. All the narratives embedded in Picoult's novel are thus linked by the hermeneutical process that created them, that is represented by them and that they in turn ask from the readers.

As Ricoeur points out in *The Rule of Metaphor* (2006, p. 6), the work of interpretation involved in understanding a metaphor is itself part of the knowledge provided by metaphorical language, which, in the case of Jodi Picoult's novel, could be translated as follows: the different perspectives from the characters given to the reader are part of the reader's interpretation and they underline the role of the very process of building a way of seeing the world.

I was born because a scientist managed to hook up my mother's eggs and my father's sperm to create a specific combination of precious genetic material. (pp. 7-8)

The Fitzgeralds (Sara and Brian) have a two-year old daughter, Kate, who has acute promyelocytic leukemia and are informed by the oncologist -- Dr. Chance -- that, since Kate's brother, Jess, is not a genetic match, they have to find an unrelated donor in the national marrow registry or have another child, a savior sibling (Anna). Interestingly, the slippery slope argument related to the use of IVF (medically-assisted reproduction) is part of a conversation between the reporter for the newsmagazine, Nadya, who interviews the Fitzgeralds, and this couple:

Nadya looks down at her notes. 'You've received hate mail, haven't you?'

Brian nods. 'People seem to think that we're trying to make a designer baby.'

'Aren't you?'

'We didn't ask for a baby with blue eyes, or one that would grow to be six feet tall, or one that would have an IQ of two hundred. Sure, we asked for specific purposes – but they're not anything one would ever consider to be model human traits. They're just Kate's traits. We don't want a superbaby; we just want to save our daughter's life. (pp. 102-3)

According to the slippery slope argument, by allowing savior siblings, which may be morally acceptable, we will start a slide towards other practices that are ethically unacceptable, such as creating designer babies. In bioethical discussions of PGD and Prenatal Diagnosis, eugenics and slippery slope are key concepts that refer to the potential danger of opening the lid of the Pandora's box, leading to a perception of humanity based only on Utilitarianism. This utilitarian attitude could range from treating the other as an Object to assuming the right to create tailor-made human beings (eugenics, the science of improving the human stock according to Francis Galton's definition in 1883). On top of this, PGD is ethically controversial because of the surplus embryos, that may be destroyed in spite of being healthy:

The doctor was able to screen several embryos to see which one, if any, would be the ideal donor for Kate. We were lucky enough to have one out of four – and it was implanted through IVF. (p. 102)

In *My Sister's Keeper*, the IVF is used as a technical procedure to find out an HLA matched donor, combined with PGD to select the embryo that would save Kate and it is precisely this saviour trait that seems to efface the identity of Anna, who is born with the purpose of giving life to her sister:

Although I am nine months pregnant, although I have had plenty of time to dream, I have not really considered the specifics of this child. I have thought of this daughter only in terms of what she will be able to do for the daughter I already have. (p. 100)

Considering Kant's principle of humanity, *which states that one should act in such a way that you always treat humanity, whether in your own person or in the person of another, never simply as a means, but always at the same time as an end*, Sara's statement quoted above can be read as the disclosure of the potential utilitarianism underlying some procedures of IVF. There are a number of fallacies misguiding the reflection upon the use of IVF, and one of them is the conviction that couples have the right to have a child, as if the child could be considered a commodity, something that one can possess, the object of another's power. Autonomy is often used to justify the translation of the *wish* to have a child into the *right* to have one, which is also fallacious, because autonomy can only be ethically acceptable when it is applied to oneself or to the respect for the other, never as a claim for the other, in this case, a claim for the child to be born. (Patrão Neves, M.C., 2008)

When the Fitzgeralds decide to have another child to save Kate, they act out of the assumption that they have the right to choose between having another child or letting Kate wait for a donor and probably die. From a Kantian perspective, autonomy is the intrinsic characteristic of the Will that makes it rule for itself according to a maximum that should become a universal law. Therefore, freedom and morality are dependent upon each other, and the community built on these principles is open to the respect for the person seen as an end in him/herself and not only as a means. The recognition of one's dignity by the others is undermined by a narrative that reduces Kate to her disease and her siblings to *stereotyped* figures in a plot:

'Don't mess with the system, Anna,' he (Jess) says bitterly. 'We've all got our scripts down pat. Kate plays **the Martyr**. I'm **the Lost Cause**. And you, you're **the Peacekeeper**.' (our highlights, p. 15)

The isolated individualism, where duty is replaced by the right to have and to be according to the individual's wish, is the result of seeing autonomy as the quality of being free from all external coercion (negative meaning), which contrasts with the respect for autonomy defined by Beauchamp and Childress:

To respect an autonomous agent is, at a minimum, to acknowledge that person's right to hold views, to make choices, and to take actions, based on personal values and beliefs. Such respect involves action, not merely a respectful attitude. It also requires more than non-interference in other's personal affairs. It includes, at least in some contexts, obligations to build up or maintain other's capacities for autonomous choice, while helping to allay fears and other conditions that destroy or disrupt their autonomous actions. (Beauchamp, T.L.; Childress, J.F., 2001, p. 63)

To enact this respect for autonomy, one should not take this principle as an isolated one, ruling over the other bioethical principles, as if it were autonomous from beneficence, nonmaleficence, integrity, solidarity and vulnerability. In fact, individuals are *emotional, embodied, desiring, creative, and feeling, as well as rational, creatures (Mackenzie, C.; Stoljar, N., 2009, p. 21)*, and only by acknowledging these features, do we respect each individual's autonomy, the capacity to choose their course of action, as well as their own communities, the so called *communities of choice*:

[T]o value these communities is to reject the strong descriptive claim that we are so constituted by social relations and shared values that we are unable to reconsider our attachment to them. (ibidem, p. 68)

Interestingly, relational autonomy and the agent's freedom of choice imply human features that are also worked out by reading literary texts, namely *memory, imagination and emotional disposition and attitudes* (ibidem, p.21).

Reading *My Sister's Keeper* in search for Anna's identity - *the sister's keeper* referred to in the title - we are faced with a narrative about *invisibility* and *ready-made scripts*, with characters looking forward to having their autonomy/identity respected/recognized:

My throat closes like a shutter of a camera, so that any air or excuses must move through a tunnel as thin as a pin. I'm invisible (…) (p. 54)

My father looked right at me, but he didn't answer. And his eyes were dazed and staring through me, like I was made out of smoke. / That was the first time I thought that maybe I was. (p. 245)

Parents control everything, unless you are like Jess and you do enough to upset them that they'd rather ignore you than pretend you actually exist. (p. 302)

By acting according to one's values, we actually give value to the Value and this could stand as the main argument for being against the use of PGD to save an existing child: the act of having a child for utilitarian reasons withdraws the value of the dignity that we apparently address to the life we are trying to save. The deliberation process that leads to the decision of *giving birth to a saviour* does not focus on the context where the decision will be acted out, but only on two elements of the context –the sick child and the parents. Therefore, we could say, that the ethical issues of *My Sister's Keeper* are raised by a deliberation model supported by a linguistic structure, which is based on a substitution theory or the theory of making one term invisible while putting the other on the stage. This linguistic structure or trope, which fosters the invisibility of some characters and the excessive visibility of others, is metaphor considered as the trope that allows us to see a familiar thing in a new light. For Aristotle, metaphor – e.g. *Achilles is a lion* - borrows from one domain (that of animals) and is a substitution for a word belonging to another domain (that of people), creating an alien effect and providing the reader with new information. The substitution theory underlining this concept of metaphor on the level of the word is related to the reasoning strategy used to decide whether to have a savior sibling for Kate. In fact, if one deliberates by considering the individual meaning of a certain human action (PGD as an instrument used to have a matched donor, a medicine embryo, a saviour) and its consequences, without taking into account the values underlying it and the narratives of the different individuals involved, then we could say that the deliberation process would be ruled by a metaphorical/substitution theory. This is the main reason why Anna tells her story against a narrative that tries to efface her; the reason why this novel is made up of different narratives, each one trying to build up their own identity - the narrative identity that bridges the gap between the *Ipse (who I am)* and the *Idem (what I am)* (Ricoeur,1992); the reason why Anna sees herself being looked at as a word replacing another word – Kate. Paradoxically, Kate's voice is never heard except for the echo of her words in other people's mouth and after Anna's death. It is ironical that the one whose life is being kept at the expense of respecting the others' autonomy is not given her own voice until her sister's death.

On the other hand, we could consider metaphor as a trope based on tension and not substitution, on interaction and not on replacement. For Ricoeur metaphor works not on the level of individual words, but at the level of the sentence and of the discourse, thus it does not work by substituting a *deviant* term for another *proper* term, but by the interaction between the focus (Anna) and the frame (Kate) within the context of the whole sentence (the family). *Anna is Kate* is the metaphor that should not have been accepted by the family at the moment they considered having a child that was not part of their parental project and that was born for purposes other than giving life to her. The other metaphorical proposition – *Sara and Brian are Kate* – should also have been eliminated if the deliberation process had been carried out by considering all the elements that are actually affected by it: Sara, Brian Kate, Jess and Anna. The first step in this deliberation procedure should be to analyse *the context*, the *conflicting values/principles at stake*, to reflect upon the *situational factors* that influence the ethical decision making: life stage, cultural background, general knowledge and specific information about the issues being discussed, peer pressure, social consensus, seriousness of consequences and individual characteristics, such as rule orientation and denial of responsibility. By applying this framework of analysis to each character's course of reflection and decision making, we are allowed to actually practise the ethical deliberation process, becoming aware of the key role played by **Orientation**, i.e. the role played by the decision maker as the subject of the action (the characters of the novel), as an external advisor (the readers, when they step out of the novel and perceive it from the border line between reality and fiction) or as an element of an organization (the characters of this novel who play the role of doctors in hospitals, geneticists in labs, judges in courts). Moreover, by getting inside the story as readers who see from the characters eyes, we are also faced with the impact of moral intensity on ethical decision making, mainly the impact of **temporal immediacy, probability of effect and proximity**. On the other hand, moving out from the plot of the novel to our own *story*, we can now have a wider and at the same time deeper view of the ethical issues at stake, which provides us with the possibility of producing an answer and yielding a choice or decision, but not of finding **the** right answer, since, as we stated before, this is not the aim of ethical deliberation.

Let us focus now on Anna's decision to stop being a donor to Kate and on Kate's decision to stop being submitted to medical procedures aimed at finding the cure at all costs. Anna builds her own narrative based on key concepts developed throughout the story, mainly the concept of otherness, utilitarianism and invisibility. It is a narrative written both by Anna's experience and by her parents' version of their family's life. Anna decides to stop to stand up for her autonomy and integrity. On the other hand, there is Kate, whose narrative is mostly conveyed by other characters' voices, thus making us read it as a narrative about an identity that has been reduced to one single trait: cancer. Her decision to stop is thus motivated by the same principles that justify Anna's decision: autonomy and integrity. If we go back to the moment when Sara and Brian are faced with the choice of using PGD to have a matched donor for Kate, they also claim the same principles underlying their ethical judgment, their ethical intent and consequent behaviour: in fact, they also act out of respect for their reproductive autonomy and to protect Kate's integrity. By following the ethical deliberation path of these characters, as if we were them, not only do we feel the urgency to reach a decision, but we also perceive the situation as ethically challenging due to the moral intensity conveyed by the literary text. We also become aware of the fact that principles and theories are only meaningful when they are located in time and place, affecting the lives of subjects whose deliberation procedure is supported or weakened by individual and social circumstances. Not every route is ethically permissible, but there is surely more than one path that can be followed when deliberating upon controversial ethical issues.

The novel's adaptation to the cinema (directed by Nick Cassavetes, written by Jeremy Leven and distributed by New Line Cinema, Warner Bros. Pictures) has worked as the search for a different perspective of the deliberation process on the ethical issues of using PGD to have a saviour sibling and of knowing when to start palliative care. It is interesting to notice that the use of a different artistic medium has given back the mystery that vanished from the fictional text. In fact, the movie gives Kate the voice that the book does not let us hear and keeps both Kate and Anna in a constant tension. Therefore, Anna is portrayed as the one who keeps Kate alive and the one who helps Kate keep her dignity till the end. Death is present from the beginning of the novel and of the movie, but the former fights against it and the latter makes it part of the narrated lives of the characters, thus making them and the viewers aware of everyone's vulnerability. By keeping Anna alive at the end, the film argument introduces a significant twist in the story, which can be interpreted as an expression of respect for autonomy. It is this twist that makes us finally catch the magic eye picture: we can only see Kate from the background of the picture if we let Anna become visible; we can only see Anna when Kate is allowed to tell her own story; we can only see ourselves by narrating our own story to the *Other*, with and for the others:

> *Between the imagination that says 'I can try anything' and the voice that says 'everything is possible but not everything is beneficial (understanding here, to others and to yourself)', a muted discord is sounded. It is this discord that the act of promising transforms into a fragile concordance: 'I can try anything', to be sure, but 'here is where I stand!* (Ricouer, P. 1992, pp. 167-8)

ABSTRACT

Regions with a strong knowledge-based economy need, now more than ever, their future generations to show a strong scientific literacy. Literature points to the importance of teaching methods in achieving strong scientific literacy; schools are essential in meeting this challenge. The current study, based on the the 2006 data of OECD's Program for International Student Assessment (PISA) focus on the effect of four different teaching methods on student scientific literacy. The study includes 3843 students from 151 schools in Flanders. Controlling for social background, gender and other student or school characteristics, the data are analyzed using multivariate multilevel regression analyses. The results show, surprisingly, that innovative classroom practices, such as class debates and the possibility for students to do their own investigations, have a negative influence on scientific literacy. Relating scientific topics to real situations and doing hands-on activities positively affected scientific literacy. Interest in science also increases when the content of the science lessons is put into a broader perspective. To conclude the results suggest that 15 year students profit the most from a teacher that focuses on models or applications in science and allows students to do hands-on activities.

Keywords: *scientific literacy, attitudes towards science, multilevel analysis, teaching methods*

INTRODUCTION

Knowledge-based economies, such as the Flemish region in Belgium, have a need for graduates with a strong scientific literacy. Therefore schools and teachers should embrace the most effective way of teaching science in secondary education. In 2006, PISA measured student outcomes in science. The results showed Flanders to be at the 8th place of all OECD countries for scientific literacy. Furthermore, PISA also assessed which didactical methods are used in the science lessons. These data create an opportunity to examine which teaching method results in strong student scientific literacy.

The current study is a secondary analysis of the PISA data and adds the connection between student outcome and the teaching method with control for different variables like gender, social status, language and origin, using a multivariate multilevel analysis on the student and school level.

The Flemish government of education determines final terms all students should reach. This is controlled by an inspecting committee but schools can choose the didactical method they use to reach the terms. Therefore we can expect significant differences in teaching methods.

THEORY

The last two decades, a lot of research has been done about educational effectiveness (e.g. Muijs & Reynolds, 2001; Creemers & Kyriakides, 2006). Effectiveness is defined as the degree in which schools succeed in obtaining their goals. For our study that is achieving a strong student scientific literacy.

Scientific Literacy

PISA defines scientific literacy as an individual's scientific knowledge and use of that knowledge to identify scientific questions, to acquire new knowledge, to explain scientific phenomena and to draw evidence-based conclusions about science-related issues. Also included in the PISA definition is understanding the characteristic features of science as a form of human knowledge and enquiry, and being aware of how science and technology shape our material, intellectual and cultural environments. Finally, for PISA, scientific literacy also includes the willingness to engage with science-related issues, and with the ideas of science, as a reflective citizen (OECD, 2007).

Scientifically literature students are able to deal with real life situations that involve science in a personal, social and global context. This ability to face such situations requires different competencies, such as identifying scientific issues, explaining phenomena scientifically and using scientific evidence. These competencies are influenced by knowledge and attitudes. Knowledge includes both scientifically content knowledge and knowledge about science.

The two attitudes in the PISA framework are: self efficacy in learning science and general interest in science. Those are directly related to goals of the European government (European Commission 2004) namely that more students study science and choose science as a career opportunity.

Teaching method

Creemers and Kyriakides (2006) describe which factors can enhance the effectiveness of schools. Their results point towards the teacher's instructional role, that was found to be consistently related to student outcomes. The quality of teaching and learning provision, supported by strategic teacher professional development matters most in affecting students' experiences and outcomes of schooling throughout their primary and secondary years (Rowe, 2003). Research on the determinants of high quality education shows that the teacher is the decisive factor (Barber & Mourshed, 2007). Constructivist learning theory, which was first described by Von Glasersfeld (1989), sees learning not only as an addition of information to existing knowledge but also as a reconstruction of what is already known. Learners are not a blank slate, and knowledge cannot be imparted without their making sense of it through a lens of their current conceptions. According to constructivism, children learn best when they are allowed to construct personal understanding based on experiences and reflecting upon those experiences. A constructivist classroom is characterised by students working in groups and learning as being interactive and dynamic; there is an emphasis on social and communication skills and on the exchange of ideas. In a traditional, nonconstructivist classroom, students work alone, learning is primarily achieved by repetition, and textbooks guide subjects.

Apart from the teacher's approach to teaching science, several factors are known to influence student outcomes, like school population, curriculum, social background, language spoken at home and gender. Also self efficacy in studying science and interest in science have been demonstrated to be of influence on student outcomes (OECD, 2006).

To examine the influence of the different styles of education it is necessary to control for school and student characteristics simultaneously in, using a multilevel approach (De Maeyer, van den Bergh, Rymenans, Van Petegem, & Rijlaarsdam, 2010).

School characteristics
Schools have been demonstrated to influence student outcomes (e.g. Hirt, Nicaise, von Kopp, & Mitter, 2007; Van Damme, Van Landeghem, De Fraine, Opdenakker, & Onghena, 2004; Veenstra, 1999).

A relation between average economic, social and cultural status (ESCS) from the school and the students outcomes can be expected (Veenstra, 1999; Van Damme, Van Landeghem, De Fraine, Opdenakker, & Onghena, 2004). The 2003 PISA data demonstrated large differences in student outcomes on mathematics in Flanders (Hirt, Nicaise, von Kopp, & Mitter, 2007). These differences can be partly explained by the school, and more specific by the school's cultural capital (Franquet, De Maeyer, & Kavadias, 2010).

Not only the quality of the lessons will have an effect, also the quantity is important (Creemers & Kyriakides, 2006). The actual time spend on science lessons has to be taken into account. When students choose a more scientific orientated study they will spend more hours in science class. Because the number of hours depends on the actual chosen study subjects and not on the educational track it is necessary to add the number of hours in the research model.

Student characteristics
Every pupil is different. They can differ in background, gender, language or others. Not all specific characteristics have an influence on school results. Social status, origin, language at home and gender are predictive indicators and are often used in school effectiveness research (Muijs & Reynolds, 2001).

Previous PISA research shows that economical, social and cultural status has an influence on students results (De Meyer & Pauly, 2007). In Flanders science achievement is higher than the OECD average, both for students with a low and high socio economic status. On the other hand the impact this status is bigger in Flanders than the OECD average (De Meyer & Pauly, 2007). In Flanders, students whose parents come from another country, score significantly lower than native students. The difference between both groups is also bigger than the OECD average (De Meyer & Pauly, 2007). Off course, the immigrant status is not the same has the language spoken at home. Therefore it is also necessary to take into account that students may speak another language at home than the language used to give instructions at school.

The difference between boys and girls in Flanders is not significant. Boys choose more scientific study options than girls, who prefer social studies. Because of this difference in choice some results hide a difference in science outcomes. The differences are usually bigger on school level than on region level (OECD, 2007).

RESEARCH QUESTIONS

1. Which constructivist science teaching methods have an effect on students science outcomes
2. What is the effect of a science teaching methods on students attitude towards science?
3. What is the effect of a science teaching methods style on students self-efficacy in science?

METHODOLOGY

Participants
This study reanalyzes the 2006 PISA data. PISA is initiated by the Organization for Economic Co-operation and Development (OECD) to study and compare student achievement. After a representative set of schools had been sampled in all countries, a random sample of 15-year-old students was drawn from each school. This study focuses on the 3843 students Flemish students from 151 schools who are studying general (ASO) and technical (TSO) education because these groups have a similar list of final terms in science and they had the same main curriculum at the first grade in secondary education. Both ASO and TSO are tracks which intend to lead to tertiary education; therefore the focus of this research is on this group of students.

Instruments
The PISA 2006 study was conducted as the third of the program's 3-yearly assessments of student knowledge and skills in mathematics, language and science. In the 2006 cycle, the focus of the assessment was on scientific literacy. In addition, students were administered a questionnaire assessing their background, learning habits, perceptions of their learning environment, and attitude towards science.

The research model:
The model used for this research is based upon the CIPO-model in combination with the PISA model for scientific literacy. The CIPO-model (Scheerens, 1990) refers to the importance of context, input, process and output. The output variables are knowledge and attitudes based on the PISA structure of scientific literacy. The teaching method is a process variable. School and students characteristics are the input and context items we integrate in our model as control variables.

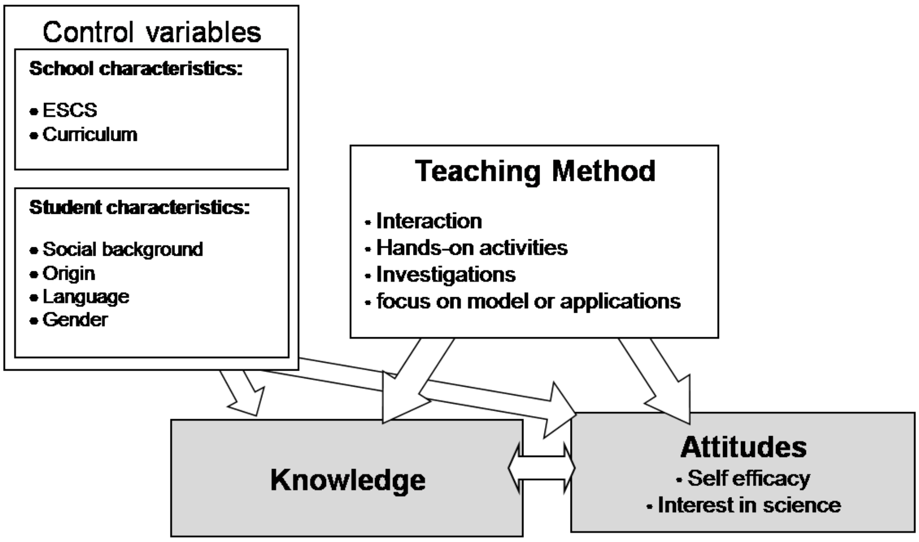

Figure 1: the research model

Variables
Three types of variables are included in our analysis: output measures on the one hand, and school and student characteristics as explanatory variables on the other. Unless mentioned otherwise, the variables described were used as they were constructed by PISA. All information on scale construction can be found in the PISA 2006 technical report (OECD, 2009). All non-categorical variables are standardized scores.

Scientific knowledge
Science abilities were measured by a 30-minute science assessment on knowledge of physical systems, living systems, earth and space, technology systems, scientific enquiry, and scientific explanations. The questions were distributed over items identifying scientific issues, explaining phenomena scientifically, and using scientific evidence (OECD, 2007). PISA 2006 reported five plausible values for science abilities, which were highly correlated (all $r(4,997) > 0.93$, $p < .001$). We selected plausible value 1 as a measure for science ability and computed a *z*-score for this scale using only the Flemish students.

Attitudes towards science
The index of general interest in science was derived from students' level of interest in learning eight different scientific topics. Examples are human biology, astronomy, requirements for scientific explanations, etc. A four-point scale with response categories from "high interest" to 'no interest" was used for the eight items scale (Cronbachs' alpha 0.82).
Self-efficacy was derived from the students' beliefs in their own ability to perform eight different tasks. Students could answer on a four point scale from "I could do this easily to "I couldn't do this" on questions like "Describe the role of antibiotics in the treatment of disease". These eight items have a high Cronbachs' alpha (0.80) for our analysis. None of the items needs to be excluded.

Explanatory variables, teaching method
PISA 2006 describes 4 science teaching methods: interaction, hands-on activities, student investigations and focus on model or application. These variables are based on 17 different questions. Students were asked to what degree four constructivist science teaching methods occurred. "When learning science topics at school, how often do the following activities occur?" was answered on a four range scale: 'in all lessons', 'in most lessons', 'in some lessons' and 'never or hardly ever' (OECD, 2007). The first variable on constructivist teaching methods is the scale 'interaction in science teaching and learning' (INTACT), indicating the frequency with which different elements of interactive teaching occur in their classroom. The INTACT scale has an acceptable reliability (alpha: 0.76). 'Occurrence of opportunities for scientific investigation' (INVEST, alpha: 0.73) and the 'Hands-on learning' (HANDS, alpha: 0.69) are constructivist teaching methods that are measured by the second and third scale respectively. The last scale for a constructivist science teaching method focuses the application of science to real life situations (APPLY) and shows acceptable reliability as well (alpha: 0.71).

Examples of different items according to this scales are:

INTACT: Interactions:

"The lessons involve students' opinions about topics."

HANDS: Hands-on activities:

"*Students spend time in the laboratory doing practical experiments."*

INVEST: Investigations:

"Students are given the chance to choose their own investigations."

APPLY: Focus on model or applications:

"The teacher uses examples of technological applications to show how science is relevant to society."

We included the constructivist teaching methods at the aggregated school level. Snijders and Bosker (1999) state that a scale's measurement error is reduced when a large number of respondents are included at the lowest level (as in our study n=3843). The large number increases the reliability of the estimate at school level. Moreover, as underlined by Griffith (2002), the appropriate level of analysis (at student or school level) is variable-dependent. When concepts measured at the individual level are nearly identical to concepts aggregated at the higher level (like 'Quality of instruction') the reliability can be assumed greater (Griffith, 2002). Therefore, the mean on each of the four scales for constructivist teaching was calculated for each school. Afterwards, each of the four scales were standardised at the Flemish school level. A positive score on for example ‘hands-on learning’ indicates that, in that school and according to the students, science is taught in a more hands-on way than in the average school.

Control variables

ESCS. The economic, social and cultural status (ESCS) of the student is composed by PISA from aspects like home possessions, highest occupational status and educational level of the parents. This variable is included both at the student level and aggregated at the school level.

CURRICULUM. An indicator for how much time students actually spent on regular science lessons. We reduced the original 5-point Likert scale from PISA to a 3-point Likert scale. The categories “none” and “less than 2h” are rescaled in a new category “few”. The category “2 to 4h” now is called “average” and the categories “4 to 6h” and “more than 6h” are composed to “much”. When these categories were reduced, we controlled that each category had an approximate equal number of respondents.

ORIGIN. Native students are born in Belgium, and so is at least one of their parents, Second generation immigrants are born in Belgium but their parents aren’t, and first generation immigrants are born in another country and so are their parents.

GENDER. A dummy variable singling out the girls in the data

LANGUAGE. Language is an individual variable because the terms used at school are often different than the register used at home. This is particularly difficult for students with an different language spoken at home (Trudgill, 2003). We only use the categories ‘same language spoken at home as during class’ and ‘different language spoken at home’. We don’t make a separation based on languages.

Analysis

This study can be divided in three main steps. First we will examine the intra class correlation between the two levels, school and student. This will be done with a basic model. Secondly we add the explanatory variables in a gross model to see what their impact is on the three outcome variables. And finally we add all control variables with school and student characteristics to control which factors at the school and student level explain variation in the outcome variables.

RESULTS

As explained in the methodology we will describe the results step by step starting with the basic model.

From the first model of the multivariate multilevel analysis (table 1) we can conclude that the variance for self-efficacy can be found for 7% at school level. Nearly the same can be said about interest in science where we find 8% at school level. This may not come as a surprise because both these variables are attitudes which are often personal aspects. So it is clear that variance can be found mostly at student level. For scientific knowledge the analysis shows that school level describes 38% of the variance. All variances are significant. We can conclude that schools matter a great deal when it comes to knowledge about science and scientific knowledge.

Self-efficacy and knowledge correlate rather strong and significant on school level (.760). So apparently schools where pupils score high on average for self-efficacy are more likely to score well on average for scientific knowledge too. Self-efficacy and interest in science have a medium correlation of .55 also at school level. All other correlations at school or student level are smaller.

On student level, high scores on one of the three variables don't necessarily go along with high scores on the other variables. A student can be highly interested in science, without having a large scientific knowledge. This means that the three dependent variables all measure some independent characteristic from scientific literacy.

Table 1: Estimated parameters first model (*correlations are italic*; variances bold*)*

School level	Self-efficacy	Interest	Knowledge
Self-Efficacy	**0.068**	*0.553*	*0.760*
Interest		**0.077**	*0.378*
Knowledge			**0.392**
Student level	Self-efficacy	Interest	Knowledge
Self-Efficacy	**0.935**	*0.354*	*0.394*
Interest		**0.925**	*0.156*
Knowledge			**0.644**

In our second model we add the four different science teaching methods (table 2). The results show 'investigations' has a significant negative relationship with self-efficacy and knowledge. This means that students from a school where there are more than average possibilities to do their own investigations in science, design their own experiments and test out their own ideas they score less than average on the topic knowledge. The same effect can be found when students have the opportunity to interact during science lessons. Discussions, class debates, and explaining their ideas too are significant negative for their science knowledge.

Hands-on activities like doing experiments or drawing conclusions from an experiment on the other hand are significantly positive for both self-efficacy and knowledge and can be seen a good style of teaching for achieving more scientific literacy. The same conclusion can be drawn for schools in which teachers who explain phenomena, use science to help students to understand the world and explain the relevance for science to our lives. Schools in which teachers that focus on models or applications in science not only have students with more self-efficacy and knowledge but also interest in science. This teaching method seems to be the only one who has a significant positive effect on interest in science.

Table 2: Estimated parameters and standard errors (S.E.) from the fixed part in the gross model

	Self Efficacy			Interest			Knowledge		
	Estimated	S.E.		Estimated	S.E.		Estimated	S.E.	
CONS	-0,012	0,023		-0,007	0,027		-0,042	0,037	
INVEST_mean_school	-0,100	0,031	*	-0,028	0,035		-0,271	0,047	*
INTACT_mean_school	-0,048	0,028		-0,014	0,032		-0,210	0,043	*
APPLY_mean_school	0,076	0,027	*	0,101	0,031	*	0,175	0,042	*
HANDS_mean_school	0,085	0,030	*	-0,013	0,034		0,161	0,047	*

* = significant at the p<0.05 level

When we look at the random part (table 3) we see that the correlations between the dependent variables are smaller in this model compared with the first one. There is still a strong positive correlation between self-efficacy and interest and between self-efficacy and knowledge. At student level these correlations are medium positive.

Table 3: Estimated parameters gross model (*correlations are italic*; variances bold*)*

School level	Self-efficacy	Interest	Knowledge
Self-Efficacy	**0.039**	*0.511*	*0.573*
Interest		**0.066**	*0.298*
Knowledge			**0.168**
Student level	Self-efficacy	Interest	Knowledge
Self-Efficacy	**0.935**	*0.354*	*0.395*
Interest		**0.925**	*0.156*
Knowledge			**0.644**

In the last model we add all student and school characteristics. The curriculum matters for all three dependent variables. Overall we can say that the number of hours of science has a positive impact on self-efficacy, interest and knowledge. This seems to be a logical conclusion because students who like doing science more often choose scientific studies than others and they feel more confident in studying science which will lead to a bigger self-efficacy.

The economic and social status of the student also has a positive influence on self-efficacy and knowledge but is not a significant predictor for interest in science. Schools with higher than average ESCS-score also have a positive effect on self-efficacy and knowledge, but not on interest. Interest is a very personal aspect which has no relationship with social background or school.

Second generation immigrants have a lower score in knowledge than first generation and native students. First generation students seem also to have more self-efficacy than both other groups. For interest in science there are no significant differences.

Students that speak another language at home than in the classroom, show a large and significantly lower score on knowledge. For interest and self-efficacy, the language spoken at home has no significant effect.

Girls score significantly worse than boys on all three dependent variables but the effect is twice as big on self-efficacy and knowledge as on interest. Probably self-efficacy is more related to gender than the style of teaching as we can see that girls have a significant lower score (-0.272 SD) than boys. Girls also seem to be less interested in science than boys (-0.125 SD) and they score 0.263 standard deviations lower on knowledge.

Table 4: Estimated parameters and standard errors (S.E.) from the fixed part in the net model

	Self Efficacy			Interest			Knowledge		
	Estimated	S.E.		Estimated	S.E.		Estimated	S.E.	
CONS	0,189	0,034	*	0,055	0,039		0,243	0,037	*
INVEST_mean_school	-0,055	0,029		-0,014	0,036		-0,189	0,039	*
INTACT_mean_school	0,000	0,026		0,015	0,033		-0,094	0,036	*
APPLY_mean_school	0,044	0,024		0,083	0,030	*	0,117	0,033	*
HANDS_mean_school	0,045	0,027		-0,033	0,034		0,094	0,037	*
CuSmall	-0,263	0,039	*	-0,178	0,040	*	-0,351	0,032	*
CuLarge	0,175	0,040	*	0,201	0,042	*	0,213	0,033	*
ESCS_school	0,168	0,060	*	0,052	0,076		0,420	0,082	*
ESCS	0,071	0,017	*	0,032	0,018		0,084	0,014	*
Or2nd	0,191	0,119		0,220	0,123		-0,391	0,098	*
Or1nd	0,291	0,135	*	0,123	0,139		-0,209	0,110	
Language	-0,085	0,088		0,020	0,091		-0,383	0,073	*
Girl	-0,272	0,033	*	-0,125	0,035	*	-0,263	0,028	*

* = significant at the p<0.05 level

After having controlled for student and school characteristics the correlation between self-efficacy and knowledge is only half of what is was before at school level. The curriculum has a strong effect on the self-efficacy, this explains why the correlation between self-efficacy and knowledge becomes smaller in the more advanced model. The correlation at school level between self-efficacy and interest remains more or less unchanged. At student level all correlations are the same as before.

Table 5: Estimated parameters net model *(correlations are italic;* variances bold*)*

School level	Self-efficacy	Interest	Knowledge
Self-Efficacy	**0.021**	*0.515*	*0.267*
Interest		**0.057**	*0.307*
Knowledge			**0.092**
Student level	Self-efficacy	Interest	Knowledge
Self-Efficacy	**0.858**	*0.335*	*0.365*
Interest		**0.893**	*0.137*
Knowledge			**0.554**

CONCLUSION AND DISCUSSION

Although this research revealed some interesting topics, some points of discussion can be made. Investigations need to be done to explore if this results are equal for all secondary students. It is likely to think that students who have more scientific background will be able to discuss some topics and design their own experiments. Different topics within science education can also be investigated on their own. Geography and physics might need an other approach than biology and chemistry.

The results show none of the science teaching method to have a significant effect on self-efficacy after control for student and school characteristics. Student interest in science, is after control for school and student characteristics, positively influenced by the teaching method ‘focus on models or applications’. Schools in which teachers explain how a scientific idea or subject can be applied to a number of different phenomena or they explain the relevance of scientific concepts for our daily lives, have students that show a greater interest in science. Students are more interested in a subject when they know where it is useful for.

All four science teaching methods have a significant effect on the students’ knowledge about science and scientific knowledge, which is in line with previous research about teacher effect on student outcome (e.g. Creemers & Kyriakides, 2006; Barber & Mourshed, 2007).

When students can explain their ideas, discuss their opinions or have class debates they will score 0.1 standard deviations less than students who have an average amount of interaction during science lessons. The largest effect is the negative impact of student investigations. When students are allowed to design their own experiments, they can chose their own investigations or they can test out their own ideas valuable study time is wasted when we want to add knowledge to our children. The common factor in both these teaching methods is the big input students can have on the topic of the lessons.

When students can do more than average hands-on activities like practical experiments either with the help of the teacher or not, but always by his instruction, they have more chances to score high on knowledge. We can say that they learn more about science when something is actually done by the students. The largest positive effect is a teaching method that helps students to understand the connection between science in class and the world outside the school. When teachers explain the relevance of the different scientific topics this not only has a positive impact on their interest, as explained above, but also on their knowledge.

These findings support Van de Werf (2005) who concluded that children benefit from a structured education and a hierarchical structure of the syllabus. When students themselves have to set goals and find what they are supposed to learn this may not be as efficient as when the teacher does.

Our results suggest that 15 year old students can benefit from somebody explaining different scientific phenomena and their relation to daily practices, the results also suggest that they might gain more science knowledge by following an instruction and doing an experiment which is set up by the teacher. Probably the scope of possibilities in science of 15 year olds is not broad enough to explore the scientific jungle by themselves. They need a guide to lead them to the different interesting spots and keep them on the right path. When they start exploring alone they will do it superficially and not as accurate as with their teacher. Teaching methods do make a difference when science has to be taught.

ABSTRACT

The purposes of this study were to determine how pre-service science teachers' views and concepts about the nature of technology developed and what was the effectiveness of using dilemmas in instruction. A mixed methods research was employed in this study with one group pretest-posttest experimental group design. The main study was conducted with the participation of 3rd year pre-service science teachers (N=41) during 2008 spring semester. Findings suggest that pre-service science teachers' views and concepts about technology were generally at the novice level before interactions with the researcher during the instructional period, but their views and concepts have changed positively afterwards. Pre-service science teachers' views about effectiveness of dilemmas in teaching the nature of technology showed that dilemmas were found to be "useful" and "effective" in teaching and learning such understandings related to the nature of technology and provided rich thinking experiences in that regard. Here we present various forms of data that were collected throughout the semester and an analysis with recommendations.

Keywords: Nature of Technology, Technology Education, Science Education, Pre- Service Science Teachers, Dilemma, Mixed Methods Research

INTRODUCTION

We live in a world in which technology has been developing rapidly. Technology has become a part of our life and it has enclosed every part of our environment. "Modern society is dominated by the use of technology. Citizens in countries across the world are increasingly exposed to technology in a variety of forms; biotechnology, chemical technologies, transport technologies, and information and communication technologies." (Sade & Coll, 2003). When all of these are taken into consideration, in order to form a strong future, countries are aware of the fact that their citizens need to be raised as individuals possessing literacy in science and technology. However, the way science and technology are taught, play a key role in terms of attaining the desired outcomes. The vision of Turkish Science and Technology Curriculum has been ambitiously set as "educating all students, whatever their individual differences might be, as scientifically literate individuals." It is hoped that science and technology literate citizens can understand relationships and interactions between science, technology, society, and environment (MEB, 2005, p.5).

Many people immediately associate "technology" with computers and internet rather than its functional definition of "changing natural world to fulfill our needs" (Rose & Dugger, 2003, p.1). Studies indicate that technology mostly reminds electronic things and it only involves such things (e.g. Volk & Dugger, 2005). In addition, for a long time, technology has been widely defined as "applications of science." However, today, by putting aside this traditional paradigm, researchers are questioning what technology is and how it interacts with science and the society in a much deeper level (de Vries, 1996).

Approximately 60% of the American society is regarding science and technology as same things (Rose & Dugger, 2003, p.3). There is an idea in the minds that there is a strict connection between science and technology. In popular media these words are being used inter-changeably (Barlex & Pitt, 2002, p.177). It is necessary to develop the assertion that the relationship between science and technology is not a fundamental identity but a historical process. This kind of a historical evaluation indicates that "in many instances technology directed the development of science, rather than the other way around" and that it is only during the last century that science and technology formed and maintained a close relationship leading to a merger in some cases (McClellan & Dorn, 2006, p.2). "When students understand the relationship between science and technology, they realize how science and technology affect each other, how they develop in a social context, and how they are used to increase people's life standards" (MEB, 2005, p.64).

"Nature of science and technology, understanding its interaction with society and environment, obtained knowledge, understanding, and abilities are required to be used by students in seeking ways of solution to the problems" (MEB, 2005, p.60). Technology education is a considerably new topic, which does not have wide research-based and good structured class application culture (Mawson, 2007). Jones (1997) emphasizes that literature in technology education is related with direct definitions, program topics and teachers' education.

DILEMMAS

There are some arguable definitions of dilemmas in the literature. Reber (1985, p.201) proposes that dilemmas could be defined as "facing of a person with two or more cases separated correlatively and none of them is completely rewarding or not conformed to each other". Although there is an interest of social psychology on dilemmas, there exist only a few studies using dilemmas (Hirsch, Bar-On & Chaitin, 2004). Kohlberg was the first among psychological researchers to use dilemmas in his own moral development research. Teaching with dilemma approach by using dilemma stories relies on Kohlberg's studies (1963, 1984, and 1996, as cited in Settelmaier, 2004). Utilizing dilemmas take time and if a teacher wants to use dilemma stories, s/he needs a good planning for timing, to relate other topics and the theme of a story (Settelmaier, 2004). "Dilemma-based learning is an approach to thinking that focuses on the use of dilemmas to develop an individual's thinking skills" (Wood, Hymer & Michel, 2008, p.3).

Pre-service science teachers' views about environmental and moral dilemmas were also evaluated in recent studies and prospective teachers' inadequacies on the topic were revealed (Arslan, Çiğdemoğlu, & Geban, 2010). Another study showed that learning by dilemmas has a positive impact on moral views about environment (Tuncay & Yilmaz-Tuzun, 2010).

PURPOSES OF THE STUDY

The purposes of this study were to determine development of pre-service science teachers' views about the nature of technology and effectiveness of using dilemmas in teaching. For this purposes, the following research questions of this study were identified.

1. What are pre-service science teachers' views about the nature of technology before and after the instructional period? Are there any differences?
2. What are the effectiveness of using dilemmas during the development of pre-service science teachers' views about the nature of technology?

3. What are pre-service science teachers' views about effectiveness of dilemmas in teaching the nature of technology?
4. What are the implications for science teacher education?

METHOD

In this research, we used a one group pre-test post-test experimental group design (e.g. Johnson & Christensen, 2008; Cohen, Lawrence & Morrison, 2006) in which there was an instructional treatment including dilemmas. The reason of conducting research in a single group was that instructional treatment with dilemmas was done in lessons according to the topic context (topics about science and technology).

PARTICIPANTS

Before the main study, a pilot study was conducted with the participation of 4th year pre-service science teachers (N=41) who were enrolled in a Science-Technology-Society course during the 2007 fall semester, and the main study was conducted with the participation of 3rd year pre-service science teachers (N=41) who were enrolled a Nature of Science course during 2008 spring semester at a well-established teacher training faculty in a metropolitan city of Turkey.

INSTRUMENTS

In order to determine participants' views about the nature of technology before and after the instruction different data gathering instruments were utilized: The Views on Technology Questionnaire (VOTQ), interviews, and student KWHL entries.
The Views on Technology Questionnaire (VOTQ):
Participants' views about nature of technology were investigated by using VOTQ before and after the instruction. In order to construct VOTQ, 16 items related to technology were selected from Views on Science-Technology-Society (VOSTS) questionnaire improved by Aikenhead, Ryan and Fleming (1989). These items can be grouped into four categories related to:
1. Defining technology, (1st, 2nd, 3rd, and 4th items)
2. Effect of society on technology, (5th and 6th items)
3. Effect of technology on society, and (7th, 8th, 9th, 10th, 11th, and 12th items)
4. Social structure of technology (13th, 14th, 15th and 16th items)

In addition, in order to assess the participants' views, we used the same categorization system of views (namely informed, has merit, and naive) that exists in other related studies (e.g. Rubba, Bradford & Harkness, 1996; Tairab, 2001; Erdoğan, 2004). A panel of 7 experts and 3 researchers served to categorize the views about each item in the instrument (for the details of categories of each item see Aydın, 2009). VOTQ was adapted by using back translation method (Maneesriwongul and Dixon, 2004). VOTQ was translated from English to Turkish then from Turkish to English and was matched by two field experts and was controlled grammar by two field experts before asked participants. So, content validity of the adapted instrument was provided. Also, VOTQ was applied to 41 participants taken in pilot study in the first sense. As a result of the applications, the answers given by 42 participants to questionnaire including 16 items were analyzed. According to this analysis, among 656 (16x41) answers, merely 15 answers (2.28%) included one of the three choices which is repeated in all items of the questionnaire. This proportion is considerably lower than the proportions in literature (Rubba et. al., 1996 [10.03%]; Lieu, 1997 [5.93%]). Therefore, it was decided that this questionnaire could be used in evaluating the view of teachers on nature of technology. VOTQ was analyzed for each participants' views such as informed, has merit, and naïve (see Table 1).

The Interview protocol

Interview questions involved 8 semi-structured questions on nature of technology. Additionally, at the end of the interview, 3 semi-structured questions for determining participants' views about using dilemmas were used. The purpose at this point is taking participants' views on the effectiveness of the application (teaching) with dilemmas, the format of the lesson done with dilemmas, and the characteristics of dilemmas. Interviews were analyzed descriptively into seven categories that were identified from literature and participants' views.

KWHL entries

The acronym *KWHL* comes from "What I **K**now? What I **W**ant to Know? **H**ow I Will Learn It? What I **L**earned?" A chart containing a column for each of these questions is used to keep a record of participants' track of learning. Participants were asked to evaluate their learning process and the place of dilemmas during the semester. The KWHL data were analyzed descriptively and the same categories in the interview protocol analysis were used.

Dilemmas

Dilemmas were utilized during instruction as a teaching tool for raising awareness about issues related to the nature of technology. The dilemmas were composed of about 350 words and contained hypothetical scenarios with opposing views about the nature of technology such as usage decisions regarding a new technology (for the details of two opposing views of each dilemma see Aydın, 2009). At the same time while creating the dilemmas the following issues were taken into consideration: defining technology, defining technological literacy as a teacher, the effect of technology on society, the effect of society on technology, the social structure of technology, the relationship between science and technology, views about scientists and inventors, the characteristics of technology and technology education. Cases in which these topics could be discussed were constructed in dilemmas. As a result, 9 dilemmas were constructed and each week one dilemma scenario was used.

The instructional practice with dilemmas

Each dilemma was used during a 1.5 to 2 hours class period. Learners were encouraged to participate and contribute to the discussions. They were asked to discuss and support one of the two opposing views, constituting the dilemma, about the case. During and after the classroom discussions it was often seen that some students crossed the border to the other side and at the end they supported the view opposite to their initial views. It was emphasized that the fundamental aim was not advocating one "*true*" view about technology but rather the aim was, through discussions, to determine what the dilemma implies and explains about the nature of technology.

FINDINGS

FINDINGS FROM VOTQ

Table 1. Frequency of participants for each item from VOTQ.

		Categories					
		Naive		Has Merit		Informed	
Item Number	VOTQ Items	Pre-test	Post-test	Pre-test	Post-test	Pre-test	Post-test
1	**10211** Defining of technology	14	7	11	23	15	10
2	**10311** Meaning of research and development	2	1	27	20	11	20
3	**10411** Relationship between science and technology	2	2	4	4	35	34
4	**10431** Relationship between science and technology	19	9	17	19	4	11
5	**20511** Effect of society on science and technology	3	2	--	--	37	38
6	**20521** Effect of society on science and technology	1	--	2	1	38	40
7	**40221** Relationship science, technology and moral decisions	20	16	10	5	11	19
8	**40231** Relationship science, technology and legal decisions	5	4	4	4	31	33
9	**40311** Trade-offs between the positive and negative effects of science and technology	12	7	9	10	18	24
10	**40413** Relationship science, technology and social problems	2	--	10	7	29	34
11	**40511** Effect of science and technology on society	--	--	22	22	19	17
12	**40531** Effect of science and technology on society	8	5	4	2	28	34
13	**80111** Usage decisions regarding a new technology	7	5	10	6	24	30
14	**80122** Usage decisions regarding a new technology	24	11	7	10	10	20
15	**80133** Usage decisions regarding a new technology	1	--	26	25	13	15
16	**80211** Control of technological developments	--	--	24	15	17	25

When pre-test and post-test findings are evaluated, it is seen that in 9 of the 16 items (namely items 2, 4, 7, 9, 10, 12, 13, 14, and 16) there is a big shift while in 4 of the remaining ones (items 5, 6, 8, and 15) there is a small shift in favor of the post-test. However, in two items (items 3 and 11) there is no gain.

When we examine these items under 4 main conceptual schemes (Aikenhead and Ryan, 1992), we reach the following findings:

1. Defining Technology (items 1, 2, 3, 4): Significantly improved student views.
2. Effect of society on science and technology (items 5 and 6): Since there was not much room for improvement, the results show a rather steady tendency in views.
3. Effect of science and technology on society (items 7, 8, 9, 10, 11, 12): It is seen that whenever there is much room for improvement some progress was achieved although there is still a need for progress.
4. Social structure of technology (items 13, 14, 15, 16): Significantly improved student views whenever possible.

FINDINGS FROM INTERVIEW AND KWHL ENTRIES

In this section, the findings from face to face interviews and KWHL entries with participants are presented. In order to be able to present the findings altogether, they are given in categories. When the participants' views are examined, it is seen that the post instructional views are more compatible with the desired outcomes as compared to the initial views.

A) The Views on the Definition of Technology
Participants views before the instruction were in parallel with the naïve views as determined by experts in VOTQ and also in parallel with the weak views that are in the related literature. For example:

"Technology always reminds me computers directly but I mean many electronic devices, etc." **(Excerpt 3, I. Interview S12, line 11–12, before instruction)**
"I think that technology is the application of science." **(Excerpt 151, KWHL S39, line 5–6, before instruction)**

After the instruction, it was seen that there was a shift towards strong views labeled as "has merit" and "informed" For example: "To me technology is the inventions that make people's lives easier and increase their life standards." **(Excerpt 4, II. Interview S12, line 6–7, after instruction)**

"I learned that technology is not only the application of science but it is also interwoven to science." **(Excerpt 152, KWHL S39, line 43–44, after instruction)**

B) The Views on Technology Literacy
Participants views before and after the instruction were close to each other but also the post-instructional views were more parallel to the desired views in literature. For example: "[Individuals] should closely follow the technological developments, I mean the new things. [Individuals] should use those in their daily lives, I mean make use of them." **(Excerpt 27, I. Interview S9, line 29–30, before v)**

"Surely trying to use them is important to some degree but it is also important to have knowledge about it. Not only how to use it, but also how it works…" **(Excerpt 28, II. Interview S9, line 24–26, after instruction)**

C) The views on the Nature of Technology (Its features, qualities etc.)
Participants views before the instruction were in parallel with naïve views as determined by experts in VOTQ and also in parallel with the weak views that are in the related literature. But after the instruction they had views parallel to the "informed" views. For example: "I think technology can be created by using sciences like mathematics." **(Excerpt 49, I. Interview S9, line 73, before instruction)**

"Before taking this course I was not thinking that there could be negative sides of technology also." **(Excerpt 164, KWHL S28, line 5–6, before instruction)**

"In the end it [technology] advances by accumulation. For example a tool can be improved, I mean once a tool is invented they can be developed further, they can be taken advantage of …" **(Excerpt 50, II. Interview S9, line 42–44, after application)**

"I learned that when presenting technology first of all its design is very important, it should be affordable and its marketing needs to be planned in advance before it is presented." ***(Excerpt 175,* KWHL *S3, line 30–32)***

D) The Views on Relationship Between Science and Technology
There is a shift fro naïve to informed views. For example:
"Seems to me that as if both are advancing by relying on each other. At some point, as if, they are receiving support from each other." **(Excerpt 63, I. Interview S12, line 66–67, before application)**

“Before coming to this course I was thinking that technology was emerging out of science. I did not know how science and technology were related.” **(Excerpt 182, KWHL S28, line 13–15, before application)**

“Neither of them can be imagined separate from the other. By using scientific knowledge, technological stuff are being produced. For example when hammer was invented no science was applied but now there are parts onto which science is applied.” **(Excerpt 64, II. Interview S12, line 63–66, after application)**

“These disciplines were born and advanced independent of each other. However, today, science makes up the infrastructure of technological developments, and on the other hand technological developments support scientific findings and research.” **(Excerpt 183, KWHL S41, line 83–85, after application)**

E) The Views on Effect of Technology and Society Mutually
While participants could not put forward any views on this topic before the instruction, after the instruction they had views that are labeled as “has merit” and “informed”. For example: “Both are influencing each other but I do not have any idea as to what degree they influence each other.”

(Excerpt 81, I. Interview S34, line 115–116, before application)
“There are aspects of technology that increases the life standards. For example, we can find everything in the internet. Ultimately, as long as society does not accept, a technology cannot develop or gain common ground.”

(Excerpt 82, II. Interview S34, line 38–40, after application)
“I learned that there are the influence of social values, ethical values, and the factor of religion on science and technology.” **(Excerpt 199, KWHL S18, line 25–26, after application)**

F) Views on the Characteristics of Inventor and Scientist
When participants’ post instructional views are examined it is seen that they could make a better discriminate between scientists and inventors, and realize that inventors do not necessarily have to posses scientific knowledge. For example: “I used to think that inventors had to have theoretical knowledge about the inventions that they make.” **(Excerpt 206, KWHL S33, line 6–7, before instruction)**

“Scientist is a different concept than inventor… An inventor does not have to have scientific knowledge. He can produce things by his experiences, put forth practical benefits.” **(Excerpt 120, II. Interview S17, line 120–122, after instruction)**

G) The Views on Technology Education
The post instructional views of the participants were reflecting more understandings and were closer to views labeled as “has merit” and “informed”. For example:
“It’ll make our job easier to give to the interested ones [students]. Since s/he will be more attentive we will develop more quickly.” **(Excerpt 133, I. Interview S12, line 139–141, before instruction)**

“Everybody should receive education. Technology is bringing states to higher levels. For example, although the production cost of mobile phones is not that much we are paying a lot of money for them. In this way other countries are earning.” **(Excerpt 134, II. Interview S12, line 147–149, after instruction)**

“I’ve learned that it will be more effective if science and technology are taken together with education. This education should be given to all segments [of the society].” **(Excerpt 210, KWHL S32, line 39–40, after instruction)**

FINDINGS RELATED TO THE EFFECTIVENESS OF DILEMMAS IN TEACHING

It is seen that participants have generally positive views towards the questions on the advantages, disadvantages and the different point of views formed in themselves of the instruction given with dilemmas.

“The advantage was that we realized at least that that there was two ends of technology…” **(Excerpt 211, II. Interview S1, line 8–12)**

“In this way everyone was able to get information from each other when we were supporting opposing views and there were many interpretations and comments.” **(Excerpt 213, II. Interview S34, line 12–15)**

When the participants’ views on the form of using dilemmas in teaching nature of technology are examined, it is perceived that there are generally positive statements.

“I think this was a very nice and useful course. I mean after the issue was given we had a question mark in the head and that remained as a question mark throughout the week to think.” **(Excerpt 219, II. Interview S41, line 20–25)**

When the participants’ views on dilemma’s, like their interesting aspects are examined, its examples and its compatibility with scenario, positive findings are obtained.

“I mean where the story was heading was interesting, when we say something and when you lead us into other directions to think, different things were coming out.” **(Excerpt 225, II. Interview S17, line 48–50)**

“Dilemmas have an undeniable power to attract students’ attention. They are useful in that they provide opportunities to see different factors and to reanimate various elements in the mind.” **(Excerpt 228, II. Interview S41, line 64–68)**

When the participants’ views to the question of “What was the effect of lesson on my learning?” are examined, it is enabled to the idea that the application was considerably effective in learning.

“Thanks to this course we were able to see that many concepts we knew were wrong and had an opportunity to change them with the correct ones.” **(Excerpt 229, KWHL S8, line 87–89)**

“We were, certainly never, given a chance to think like a scientist. To be in her/his place. In this course you created thoughts like that.” **(Excerpt 232, KWHL S20, line 27–29)**

DISCUSSION AND CONCLUSION

NATURE OF TECHNOLOGY

It is showed that findings by different data collecting instruments on nature of technology are similar. When participants' views are examined before the applications, they generally define technology as the application of science and fulfilling the needs. This result is compatible with many studies and literature (e.g. de Vries, 2005; p.2; Yalvaç, Tekkaya, Çakıroğlu & Kahyaoğlu, 2007). However, when the participants' views are evaluated after the applications, it is seen that most of them has been far from the idea defining technology as an application of science. Similar issues are also contained in the views on the purpose of technology after the applications. The detections of participants towards the purpose of the technology are also similar in literature (e.g. MEB, 2005).

It is seen that participants' views before the applications on the relation between science and technology is compatible with literature (e.g., Rose and Dugger, 2003, p.3; Yalvaç et al., 2007). While participants thought science and technology as non-separable and claimed that there could be no technology without science before the applications, in contrast, they stated that science and technology progress separately; technological product could emerge without science and this issue should be examined from the historical account after applications. Also, many points related with nature of technology in literature (Technology Education Centre, 2008; ITEA, 1996, p.16) are compatible with the ideas of participants after the applications. For example, participants were not aware of the negative effects of technology before applications as it is also proposed by de Vries (2005; p.107). Similarly, as designated by Solomon (1997, p.155), new technologies as a result of the applications changing the lives of people both in expected and unexpected way are encountered as an issue also cognized by participants. However, it is seen that participants give a great place to the relation of technology with moral values in their views on the effect of society on technology after the applications. In this frame, it is perceived from the participants' views that although technology has an effect on society, society has also an effect on technology.

When we evaluate the findings from VOTQ as a result of the applications done with dilemmas, the participants' views after applications is more meaningful with respect to their views before applications. Besides, according to the interviews with participants and the ideas of experts, many items belong to questions in the questionnaire is inadequate in the sense of statement and explanation. As an illustration, the interviews with participants explain the case better in the topics of the definition of technology, the relationship between science and technology, technology education and the issues of technology. This result clearly states that the questionnaire should be supported by interviews in order to obtain more clarified data. This case requires that there should be more developed questionnaire prepared about nature of technology.

EFFECTIVENESS OF DILEMMAS IN TEACHING

The results reached in this research indicate that dilemmas have many advantages in teaching nature of technology more effectively:

1. It is important to become aware of the fact that at least two opposing views can be regarded.
2. Discussing opposing views with learners can create many vivid and sound examples.
3. Emerging different perspectives and comments support rapid information transfer and hence increase the effectiveness of instruction and participation to lessons.
4. Dilemmas increase people's curiosity and make people more willing to do research.
5. Dilemmas create question marks in the mind, which in turn creates interest to learn. This stabilizes the person in the argumentative state for a longer period of time.

6. The “open-endedness” in dilemmas are influential in creating different topics and aspects of technology.
7. Dilemmas create opportunities to think and somewhat behave like a scientist.
8. Dilemmas can promote multi-dimensional thinking, learning to draw meanings, and forming own ideas.

The results obtained by this research indicate that dilemmas have also a few disadvantages which can be summarized as follows:

1. Learners have a tendency to know certain results rather than adopting critical approach. The fact that dilemmas, by their nature, have two opposite poles can cause negative reactions by putting the learners in conflict.
2. Learners emphasize that they have difficulties with this instructional approach because they are not used to reaching the conclusions by themselves.

When we take above advantages and disadvantages of dilemmas into a consideration together, while using the dilemmas in science and technology education the following guideline can be followed for a better instruction:

1. In order to prevent negative reactions it is important to promote critical thinking first. Topics can be assigned one week before in order to encourage the learners to think critically in advance.
2. It is also necessary for learners to be prepared for the topic to be discussed by gathering information from different resources and becoming ready for discussion by considering a wide variety of views about the topic. In this study, it was seen that one week was usually enough for preparation.
3. Having enough time for discussion is important. Although some participants have different ideas about allocation, they generally state that time between 1.5 - 2 hours is enough for them.
4. Teacher guidance is important for teaching by dilemmas. If teacher guidance and support is not sufficient, the discussions can be distracted far away from the topic.
5. Different presentation devices and/or materials can be allowed and used.
6. Having several concrete examples supporting opposing poles of the dilemmas can be appropriate and useful for students to understand the topic.

In sum, the findings from the pre and post instructional data shows that instruction with dilemmas had a positive effect on participants’ learning of the nature of technology. This supports the findings of the previous studies (e.g. Compton & Harwood, 2003, Jones & Moreland, 2003) that if opportunities are provided for students to develop their understanding of nature of technology in an increasing and sophisticated way, their learning of technology generally increases.

Similarly, as indicated by de Vries (2005), in teaching and learning of technology, it is important to develop the understandings and points of views about technology with different teaching strategies. In order to help learners understand these aspects of technology, it is necessary to encourage them to think by themselves in detail while developing their own perspectives. As the above cited literature assert, dilemmas also provide opportunities to learn the various aspects of technology and encourage them to discover new understandings individually and foster their own points of views. Hence, we stress that dilemmas can be utilized effectively in teaching the nature of technology but they can be improved and adjusted according to the teaching and learning needs.

ACKNOWLEDGEMENT

This study was supported in part by Gazi Üniversitesi Bilimsel Araştırma Projeleri Birimi (Gazi University Scientific Research Projects Unit), with Grant Number: 04/2007-23 and project title “Creating dilemmas about science and investigating the effect of dilemmas on prospective science teachers’ understanding of the nature of science”.

ABSTRACT

The Turkish primary science and technology curriculum has been recently reformed and based on the constructivist approach. The aim of this study was to examine the effects of the activities employed in the Electricity in Our Lives unit of 6th Grade Science and Technology curriculum on the students' attitudes towards science courses. The sample of this study was two different groups of 6th grade students attending a public primary school. The treatment group was taught according to the activities included in the new curriculum, and the control group was taught according to the traditional methods. In the study, a treatment/control group pre-test/post-test design was employed. The science course attitude scale was used for data collection. Independent and dependent t-test statistics were performed for the purpose of testing the sub problems of the study. The data analysis shows that there is no statistically significant difference between the treatment group and the control group. However, the results also showed that the attitudes of female students changed in a more positive way than that of male students.

Keywords: *Science and technology, Traditional Education Method, Attitude*

INTRODUCTION

Education is in constant development along with the changing circumstances of the world. For this reason, establishing new education environments, choosing right materials and methods for effective instruction of a course as well as determination of students' interests, attitudes and needs are very important in constantly developing education programs.

Today, instead of the textbook and teacher centered approaches, student centered approach is valued. In this way students can collect information from various sources and inquiry is a means of continued learning (Doğanay, 2000). Individuals who value development and innovation, fulfill their own duties, are needed in this ever changing world. From a constructivist point of view direct transfer emotions and knowledge to learners is not possible. In the student centered learning approach students are epected to create new knowledge on top of existing textbook knowledge. Learners take an active role in the process of creating of meaning by interpretation (Yıldırım & Şimşek, 1999).

All these facts led to fundamental changes in the curricula of various countries. As a result, student centered teaching/learning approaches are now dominant throughout the world (Osborne & Wittrock, 1983; Watts & Pope, 1989; Hand & Treagust, 1991). Similarly, many studies from Turkey and abroad were investigated. Results of these investigations reveal that cooperative approach have an important impact on students' attitudes (Bilgin & Geban, 2004; Veenman et al., 2005).

One of the most important aims of science education is to enable learners' development in affective fields. Learning acquired in affective fields involves the changes taking place in individuals with respect to such concepts as values, beliefs and attitudes. Values play a significant role in the formation of attitudes and beliefs (Simpson et. al., 1994). Values help individuals develop specific attitudes and beliefs as well as serve them as standards or decision making criteria for taking decisions (Rokeach, 1973).

The construct of attitude, which has a significant place in learning, has various definitions in the literature. While Senemoğlu (2000) defines the concept of attitude as an acquired inner condition that determines an individual's choices in his/her activities against any given group of people, individuals, events and various other circumstances. Gardner defines the attitudes towards science fields as "learned a priori inclination in the evaluation of objects, humans, actions and situations in specific ways" or "propositions regarding the learning science" (George, 2000).

When science education literature is examined it is seen that attitude has a great role in attaining meaningful learning. Given the fact that education is the primary means of attitude development and improvement, teachers knowledgeable about determining attitude measurement and assessment, both in their courses and in daily life, can be an important factor in improving the quality of education offered (Alkan and Ertem, 2004). Attitudes are about handling and controlling the emotions stemming during the learning process and they have a significant role in shaping humans' behaviors. Positive or negative quality of the attitudes formed in connection with a certain set of values and beliefs directly affects the learning process and thereby shapes the individuals' future lives (Seferoğlu, 2004).

There are two important reasons for researchers to conduct a study with respect to the students' attitudes towards science courses. First of all it is determined that the attitude towards science courses supports the students' behaviors, their course choices, quality and appropriate class works, participation in scientific researches and scientific studies (Koballa & Crawley 1985). Secondly, there is a correlation between students' attitudes towards science courses and their successes (Schibeci and Riley 1986). In their studies, Peterson & Carlson (1979) have stated that the change in the success level of the students is also the reason for the change in their attitude. Moreover, the results obtained from study conducted by Gürkan and Gökçe (2001) demonstrates a meaningful relationship between the students' successes and attitudes towards science courses. According to this relationship, the more positive an attitude a student adopts towards science courses, the more successful he/she becomes in such courses.

The activities included in science education arouse students' interests and lead them question as to their priorities and thereby perceive natural events from different angles. Most of the activities in science education help change attitudes in positive manner (Aydın & Balım 2005). When the students are encouraged to participate actively in science courses and concrete learning process is established, and when cooperative and project based learning approaches are employed, it is seen that such factors contributed positively on such cognitive and affective qualities as success, high level cogitation skills, social development, self-respect and attitudes (Fidan, 1996; Açıkgöz, 1992; Korkmaz and Kaptan, 2002).

This study examining the effects of Science and Technology Education Program, which was intended for 6th grades during the Academic Year 2006-2007 and that covers education activities aiming at teaching the students basic science concepts, scientific process skills, understandings regarding science, technology, society and environment as well as scientific values and attitudes, on the students' attitudes towards science courses is important in terms of shedding light to the future education programs to be developed.

PURPOSE

The main purpose of this study was to determine the impact of activities employed in the unit entitled “The Electricity in Our Lives", which is included in the 6th Grade Science and Technology Course curriculum that is intended for scientific activities based on "by doing and experiencing", on the students' attitudes towards science course. Also examined in the study was whether or not the attitude scores differed according to gender. The sample consisted of 6th grade students in a public school.

METHOD

In this study a pre-test/post-test design with treatment/control groups was employed. The dependent variable in this study was student attitude level scores as measured in the sixth grade “electricity in our lives” unit. The independent variables were the teaching methods employed and gender. The reason for selecting the “electricity in lives” unit was that it was previously determined as a difficult subject for students. Pine, Messer and John (2001) found that science teachers had expressed that primary school students had several difficulties in the “electricity” unit. Moreover, several other studies revealed that student in all levels from elementary to university years, have had misconceptions about electricity (e.g., Tianyu & Thomas, 1991; Chambers & Andre, 1997; Azar, 2001; Lee & Law, 2001; Sönmez, Geban & Ertapınar, 2001; Büyükkasap, Samancı & Dikel, 2002; Tsai, 2003).

Sixty four 6^{th} grade students attending two different schools in a small town in Kayseri province were the sample of this study.

The science course attitude scale was developed by the authors of this study. The attitude instrument is a 5 point Likert type scale consisting of 24 items. Out of those 24 items, 15 of them include positive statements, and the remaining 9 have negative statements. The reliability study of the prepared scale has been conducted on a total number of 134 6th grade students studying at other primary schools in the same town. The data were analyzed by SPSS 11.5 program and the reliability of the scale Cronbach α was found to be .84. 4 experts' opinions were taken for the validity of the instrument.

Before performing the study, the attitude scale was administered to both test and control group students as pre-test. The experimental study was conducted in both groups for 4 hours a week throughout a period of 3 weeks. At the end of the study the attitude scale has once again been administered to both groups as post-test.

The parametric dependent and independent groups t-test was used for data analysis. As a result of the statistical analysis, the significance level was determined to be .05.

FINDINGS

At the beginning of the study period, t-test results for independent groups, which has been used to determine whether there was a difference between the test group and control group students' attitudes towards science and technology courses at the meaningful level, has been given.

Table1 Independent Groups t-test Results of the Preliminary Test Points Regarding the Test and Control Groups Students' Attitudes towards Science and Technology Course

Groups	n	M	ss	sd	t	p
Test	32	95.31	11.87	31	-.962	.340
Control	32	98.06	10.96			

According to Table 1, there is statistically no difference at the meaningful level between the preliminary test points obtained in the attitude test at the outset of the study by test group students, who are trained according to the constructivist approach in the new science and technology course education program, and that of control group students, who are subject to the science education consistent with traditional education methods ($t_{(31)}$ = -,962; p>.05).

While, according to the data in the table, the average of the attitude points of test group students prior to the application was M = 95.31, the average of the attitude points of control group students prior to the application was M = 98.06. The finding of no statistical difference at the meaningful level between the attitude points of test and control group students at the outset of the application is considered to be consistent with the purpose in terms of determination of the effectiveness of the applied course activities.

Table 2 Independent Groups t-test Results of the Final Test Points Regarding the Test and Control Groups Students' Attitudes towards Science and Technology Course

Groups	n	M	ss	sd	t	p
Test	32	110.59	9.38	31	1.251	.216
Control	32	97.34	11.30			

According to Table 2, there is statistically no difference at the meaningful level between the final test points obtained in the attitude test at the end of the study by test group students, who are trained according to the constructivist approach in the new science and technology course education program, and that of control group students, who are subject to the science education consistent with traditional education methods ($t_{(31)}$= 1.251; p>.05). While, according to the data in the Table 2, the average of the attitude points of test group students after the application was M = 100.59, the average of the attitude points of control group students after the application was M = 97.34. The finding of no statistical difference at the meaningful level between the attitude points of test and control group students at the end of the application proves that the applied course activities do not affect the students' attitudes towards science and technology course at a meaningful rate.

Table3. Dependent Groups t-test Results of the Preliminary Test Points Regarding the Male and Female Students' Attitudes towards Science and Technology Course in the Test Group

Sex	n	M	ss	sd	t	p
Girls	15	99.66	11.67	30	2.046	.051
Boys	17	91.47	10.97			

As could be seen in the Table 3, there is no difference at the meaningful level between the attitudes of male and female students in the test group towards science and technology course at the outset of the science education process which is exercised with the activities of the new science and technology curriculum ($t_{(30)}$= 2.046; p>.05). Prior to the study, the average of the attitude points of the test group female students was M= 99.66 while the attitude point average of the male students was M=91.47. When those values are considered, there is no statistically meaningful difference between attitude points of the male and female students prior to the study. Finding of no meaningful difference between the preliminary test attitude points of the test group male and female students prior to the application is considered to be consistent with the purpose in terms of determination of the interaction between sex and attitudes.

Table 4. Dependent Groups t-test Results of the Final Test Points Regarding the Male and Female Students' Attitudes towards Science and Technology Course in the Test Group

Sex	n	M	ss	sd	t	p
Girls	15	104.73	8.58	30	2.541	.016
Boys	17	96.94	8.72			

According to the Table 4, there is a difference at the meaningful level between the test group male and female students' attitude towards science and technology course a result of the science education process rendered in accordance with the activities of the new science and technology course curriculum $t_{(30)}= 2.541$; $p<.05$). At the end of the study, while the average of the attitude points of the test group female students was M = 104.73, the average of the attitude points of the male students was M =96.94'tür. According to those values, there is a statistically meaningful difference in favor of female students between the attitude points of the male and female students at the end of the study. When the attitude points of the male and female students are observed at the end of the study, it can be remarked that the female students' attitude towards science and technology course has increased more than that of male students.

The male students' attitude towards the course has also increased, but not as much as that of female students. As could be understood from the aforementioned, sex determines the students' attitude towards the course.

RESULTS AND DISCUSSION

As a result of the findings gathered from the study, the following results have been obtained.

It is possible to summarize the results obtained as follows:

According to the findings of the study, there is no meaningful difference between the preliminary test attitude points of the test group being subject to the new science and technology curriculum and the control group being subject to the traditional education methods.

According to one another result obtained from the study, there is no meaningful difference between the post application attitude points of the test group trained in new science and technology education program and the control group trained in traditional education methods. According to this result, the activities included in science and technology curriculum do not increase the students' attitudes in a positive way. However when the final attitude points of the both groups are observed, it is possible to state that there is an increase in students' attitudes in favor of the test group students, although such an increase is not statistically meaningful.

All of the statistical results obtained from this study show that the course activities used in new science and technology course curriculum do not affect the students' attitudes towards the course at a meaningful rate. Thus the finding of no statistically meaningful difference between the final test attitude points of test and control groups supports this opinion. As a conclusion it can be said that the course activities prescribed in the new curriculum do not affect the students' attitudes in a statistically meaningful level. However, the attitude points of the test group students have slightly increased after the application. Despite the fact that such an increase is not statistically meaningful, it can be said that, based on the result achieved, the attitudes of the test group students towards science and technology course may develop in a positive way.

Previously conducted studies of the similar nature also support the results of this study. Bredderman (1983) compared the efficiency based programs against traditional programs and concluded that the difference resulting from the comparison, though not being meaningful, was clearly positive. In 400 comparisons made, 32% of the students liked efficiency based programs, and only 6% of them preferred traditional programs. Based on the results of the study, Bredderman (1983) concluded that if efficiency based programs was to be applied more commonly there could be a high probability of increase in the students' attitude towards science courses.

One another result obtained from the study was that sex was influential in determination of the test group male and female students' attitude who were being educated in accordance with the new curriculum. Female students' attitude towards science and technology course is more positive than that of male students.

When the attitudes of male and female students are observed, there is a meaningful difference in favor of female students. It can be said that the applied course activities increased the attitude of female students more than that of male students. Similarly, Yaman and Öner (2006) have found out in their study entitled "A Study Regarding the Determination of Primary School Students' Points of View Towards Science Course" that the attitudes of female students were more positive than the male students. However, in his experimental study where he studied the effects of constructivist teaching strategies on the high school students' attitude towards science courses, Heron (1997) found out that employment of constructivist teaching strategies had a positive effect on the students' attitude towards science courses and that eliminated the attitude difference between male and female students. Similarly, in a study it was revealed that secondary students' negative attitudes towards science and mathematics had changed according to gender and grade level (Koca and Şen, 2006).

In this respect, the results gathered in this study are important for shedding light to the future studies to be conducted in this area and mending the deficiencies inherent in the literature.

ABSTRACT

We present Slovenian national assessment of knowledge of physics at the end of elementary education as an example of a tool to assess the knowledge of the population. Changes and reforms of school systems follow one another in a quick pace – all in the name of adjustments to the development and new challenges of the mankind and in agreement with new research results on what is the best way of teaching specific topics to children of certain age (Black, 2000; Kelly, 2009). In order to measure success of reforms one has to assess the knowledge of selected age groups and follow the trends for years. We do not know the trends of Slovenian knowledge of physics yet, because we only have data for two years, 2007 and 2008, but several typical problems in 15 years old pupils' comprehension of physics and general lack of ability of solving non-standard questions seem to be common weak points of the population. How to incorporate these results in an always developing curriculum is a difficult task and we demonstrate why this is so by a few examples.

Keywords: physics, assessment of knowledge, primary school, curriculum.

INTRODUCTION

At present the curricula for nine-year primary education (age 6-15) in Slovenia are reforming again – new curricula were prepared in 2007, but there are some formal obstacles that are awaiting to be resolved. The valid curriculum for physics dates at 1998, so the initiative for changes appeared only seven or eight years after the last curriculum changes have been adopted. Is it reasonable to change curriculum so often?

On the other hand, there is close to 20 years of history of final exams after finishing primary education. From the results we may not be able to say, if the changes in curriculum are necessary or not, but we can surely say that we do not posses reliable data on why the knowledge of physics in Slovenia is such as it was measured. Several successive assessments of knowledge of a subject should be made before attempting to change the curriculum.

Although two decades of examining the pupils after finishing primary education seems a lot of data, it is not the case for, e.g., physics. Up to 2005 mathematics and mother tongue were tested each year, but the "third" subject was selected by the pupils. The results of the exams were the basis for entering secondary school. Out of around 20.000 pupils only less than 100 choose physics each year, so our assessment of knowledge of physics was neither representative nor accurate. Since 2006 the character of the test at the end of primary education changed from being selective into being an assessment tool for the population. There are still three subjects assessed, but the "third" subject is chosen by the Ministry of Education. Each year four "third" subjects are selected and the knowledge of each is assessed on a representative one quarter of the population – around 5000 pupils. Knowledge of physics was assessed in 2007 and 2008 and is expected to be reassessed in

2011. One of the reasons for the 2009 and 2010 gap is big coherence between the 2007 and 2008 results, so we did not expect detectable changes in a short time and have advised the Ministry not to repeat assessment right away.

In the present paper accumulative results of two successive national assessments of knowledge of physics after finishing primary school are presented. In both assessments many similar strong and weak points in the knowledge and understanding of physics are found. This gives reliable insight into the present level of knowledge of physics among Slovenian pupils at the end of the nine-year primary education when they are aged averagely 15. But, from the results we cannot determine why there are certain weaknesses in the concepts or why the pupils misunderstand certain laws of nature. We can only speculate about the reasons. In the paper we give a few examples of the questions that illuminate weak physics, but at the same time do not unequivocally give reasons for such weaknesses in terms of required changes in curriculum or at least in the way physics is taught.

In order to really understand why there are problems with some topics, we should change the way these topics are taught and measure the knowledge again. Only after several repetitions of such tests one would have some solid ground for the changes and only than should the changes of the curriculum be made. We all know that nobody in politics has the patience to wait so long. New changes of the curriculum are often made before the school manages to fully appreciate the last changes. With this respect we do not dare to suggest changes in the curriculum, but we rather give some hints on what the teachers (in Slovenia) should pay attention to while teaching physics.

The paper is organised in three larger units. In the next chapter the assessment is presented in detail in order to understand the measuring tools that are used. In the following chapter a few typical problems are presented. Finally, the implications for the curriculum development are summarised in conclusions.

NATIONAL ASSESSMENT OF PHYSICS

The national assessment exam in physics is set up of 20 written problems, spanning the syllabus of physics (the last 2 years of elementary school, 8^{th} and 9^{th} grade, 2 hours per week) and physical topics in the subject "natural science" (the 7^{th} grade, about 18 hours in the entire year). Depending on the length and complexity 1 to 4 points are assigned to each problem, but the overall sum is fixed to 36 points. There is a point assigned for each step in solving each problem. The average score (Figure 1) was 16.8 points, i.e., 46.6 % of maximum possible number of points for 4,548 pupils in 2007 (Bajc, Beznec, & Verovnik, 2007) and 15.8 points (43.8 % of maximum) for 4993 pupils in 2008 (Bajc, Beznec, Ferlinc, Semen, & Verovnik, 2008). All cognitive levels after Bloom (1956) are present in the test, so this result is not a surprise, as we include only about 20 % of low cognitive levels (knowledge and recognition, level I), about 55 % of intermediate cognitive level (comprehension and application, level II), and about 25 % of high cognition level (analysis and synthesis, level III). The distribution of questions is so much in favour of higher cognitive levels, because physics is all about understanding nature. Thus knowing definitions or recognizing correct units or wording of laws of physics is not enough. What pupils should gain from physics is a scientific approach to nature, the ability to recognise key variables in particular relations and to learn how to combine theory and observations. In addition, they should develop critical thinking. For example, they should learn how to ask relevant questions related to particular phenomena. One of the major advantages of physics in comparison to other nature science subjects is that experiments can be made relatively simple, preferably with just one variable to observe, and can easily be repeated. On top, theoretical models reproduce the experiments well, if the experiments are chosen correctly. All this should be used to encourage the pupil’s curiosity and direct it into development of a natural scientific approach when observing nature.

The distribution of the points over the representative sample of pupils is shown in Figure 1. In order to generalise the results, four groups of pupils with distinctively different overall results have been generated. In the *G1* group (Figure 1, line-hached bars) there are around 10 % of pupils whose result is around the first quartile border, i.e., such pupils that roughly 20 % of all pupils did worse than *G1* group and roughly 70 % of the pupils did better than the pupils in the *G1* group. Similarly, the *G2* group (Figure 1, grey bars) includes pupils around second quartile (45 – 55 %), the *G3* group (Figure 1, doted bars) includes pupils around third quartile (70 – 80 %), and the *G4* group (Fig. 1, black bars) includes pupils with the best results – upper 10 % of the population.

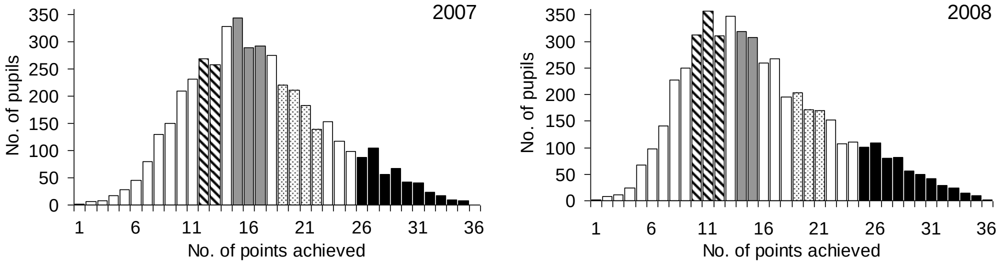

Figure 1: Overall distribution of the assessments in 2007 (left) and 2008 (right).

Each assigned point of the questions is placed in a group according to the success of the pupils at a particular sub-question in each group of pupils. So the problems are also subdivided into groups *G1*, *G2*, *G3*, and *G4* (Table 1). A sub-question is put in a group that is named by the group of pupils with the lowest overall knowledge, who have successfully answered the sub-question. We decided that a sub-question is successfully answered by a particular group of pupils, if more than 2/3 of the group answered correctly. If, for example, a sub-question is answered correctly by 50 % of the G1 pupils, by 70 % of the G2, 80 % of the G3, and 90 % of the G4 pupils, we put it into a group of G2 questions. An additional group of questions is formed by the sub-questions that have statistically not been successfully answered even by the best 10 % of the population. These sub-questions fall into the "*above the G4*" group. General conclusions are drawn from the common characteristics of each group of sub-questions. We illustrate the analysis by a few examples.

Table 1: Distribution of the sub-questions (i.e., points) according to the group of pupils that successfully solved a problem.

Group	Year 2007	Year 2008
G1	6	6
G2	3	2
G3	4	7
G4	17	14
Above G4	6	7

A detailed argumentation of the findings of the 2007 and 2008 assessment is beyond the scope of this paper. We summarise the findings here and advise more interested readers to read the official yearly report on the 2007 and 2008 assessment of knowledge of physics (Bajc et al., 2007, 2008).

EXAMPLES OF THE PROBLEMS

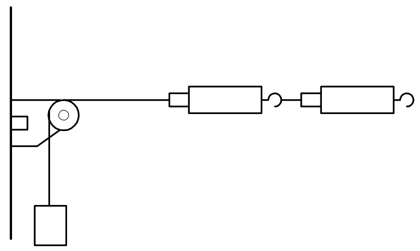
Due to space limitations only a handful of problems are presented with the emphasis on the possible multiple interpretations of the results. These problems are the ones that can be misused by the educational authorities and policy makers. We hope to illustrate that changing curriculum is a delicate matter and should, in our opinion, be made preferably in a slow continuous way rather than dramatic changes. In particular we oppose making successive drastic changes in short – a few years, for example – time intervals.

PROBLEM EXAMPLE 1

This example from the 2007 assessment test is a multiple choice question related to equilibrium of forces and third Newton's law (Figure 2). The original wording of the problem reads:

A one kilogram weight in the figure is at rest. What are the forces shown by each of the two dynamometers?

Encircle the letter in front of the correct answer.



A The first 5 N, the second 5 N.

B The first 5 N, the second 10 N.

C The first 10 N, the second 5 N.

D The first 10 N, the second 10 N.

Figure 2: An example of a multiple choice question related to the first and the third Newton's law, taken from the 2007 assessment test.

The number of pupils choosing particular answer was: A – 2214, B – 659, C – 437, and D – 1123. The correct answer is D: each dynamometer shows a force 10 N.

Although this turned out to be one of the most difficult questions in the entire 2007 test and its content could be a topic for itself, at this point we want to stress a different aspect. This problem is a fine example of the advantages of a multiple choice question.

The number of the pupils that answered correctly is small for all pupil groups (Table 2). We infer that on average the pupils do not understand the third Newton's law or they do not know it or maybe they do not know how to use in this particular situation. We also notice that pupils with better overall score solve the problem better than the pupils that did not do so well the entire test. If in the analysis of the results only the correctness of the answers is taken into account, there is nothing else we can get from this problem. We could only speculate on why the score is as bad as it is.

Table 2: The statistics for the first problem example.

Portion of pupils solving the problem [%]				
G1	G2	G3	G4	Overall
20.3	25.1	27.9	38.3	25

There could be a lot of information in the distribution of the selection of the wrong answers and suitably constructed multiple choice questions provide a possibility to get additional insight into the pupils' reasoning. In this problem, wrong answer "A" was particularly tempting for the pupils, as they selected it two times more frequently than the correct answer "D". Since the answers "B" and "C" are far less frequent, we can conclude with high certainty that the pupils confuse first and third Newton's law or that they do not distinguish between the two.

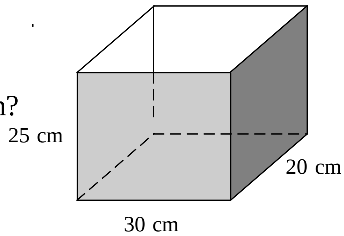
In order to go deeper into pupils reasoning, additional questions related to both Newton's laws should be asked and answered, but in the framework of the national assessment this is not possible due to logistic limitations. National assessment has to span the entire curriculum in a limited time, so details are sacrificed on account of a global picture.

One may be tempted to change the part of curricula that is related to Newton's third law, advocating the topic to be too difficult for the population in the primary school and 'proving' it by the bad overall score of the problem example 1. On the other hand, extended analysis including the distribution of the selection of the incorrect answers indicates that the reason might not be the difficulty of understanding the third Newton's law. It seems that the problem is the distinction between the third and the first Newton's law. So, instead of dropping something out of curriculum, one could advocate to pay a little more attention to the distinction between the two Newton's laws. Since it is not 100 % clear from the national assessment results, which option is better, many different curriculum changes can be justified depending on the interpretation of the results.

PROBLEM EXAMPLE 2

This example from the 2008 assessment test is an open ended question with four sub-questions related to volume, mass, density, weight, and pressure (Figure 3). The original wording of the problem reads:

An aquarium has length 30 cm, width 20 cm, and height 25 cm. It is fully filled with water.



a) How many litres of water are in the aquarium?

Answer: ______________________

b) What is the mass of the water in the aquarium?

Answer: ______________________

c) What is the weight of the water in the aquarium?

Answer: ______________________

d) For how much is the pressure at the bottom of the aquarium larger that the pressure at the water surface?

Answer: ______________________

Figure 3: An example of a multiple open ended question checking relations between volume, mass, weight, and hydrostatic pressure.

This problem was intended to measure the ability of pupils to convert volume to mass, mass to weight, and finally, to calculate the hydrostatic pressure. Density of water is given as a supplement of the assessment test.

Table 3: The statistics for the second problem example.

Portion of pupils solving the problem [%]					
Sub-question	G1	G2	G3	G4	Overall
a)	23.1	49.0	79.4	95.6	50
b)	12.9	32.7	72.3	96.1	42
c)	3.5	17.9	54.3	94.3	31
d)	0.3	2.6	12.7	54.0	11

As one can see from table 3 and figure 4, the pupils with the best overall score (group G4) have no problem calculating the volume and converting volume to mass and weight of water. But even in this group only every second pupil correctly calculated the pressure difference between the surface and the bottom of the aquarium. For the first three groups of pupils, G1, G2, and G3, for each succeeding sub-question the score is substantially smaller than the score for the preceding sub-question (Figure 4). Besides the score itself we would like to know the reasons for these relatively bad results. Because this is an open ended problem, it is extremely time demanding to read and group into classes all given answers to particular sub-question and to make further conjectures about possible lack of knowledge that produced observed results. Neither the analysis centre at the National examination centre nor the Subject committee for physics have the man power to do such detailed analysis, so we are left with speculations.

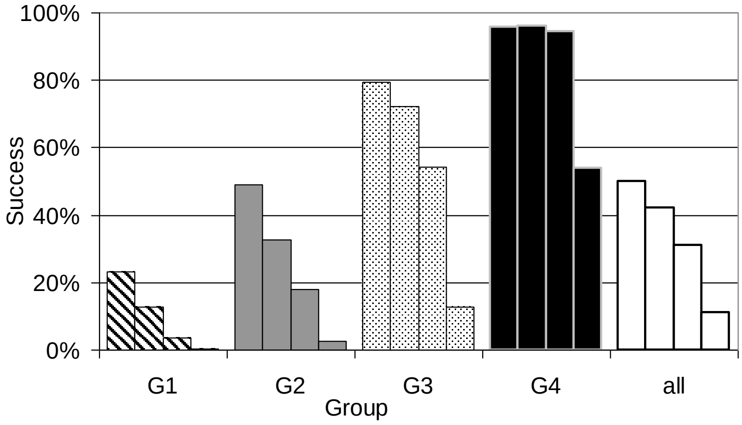


Figure 4: Success of the representative student groups in sub-questions of the second problem example. For each student group the first column represents the success in sub-question a), the second in sub-question b), the third in sub-question c), and the fourth in sub-question d).

The incorrect results to sub-question a) can be, for example, a consequence of not knowing how to calculate the volume of the aquarium or of not knowing how to convert units or of a simple mistake in calculation or not writing the units beside the calculated number, etc.

We definitely can identify that the overall success of this problem is not as good as we expected, but we do not know the most frequent reason for the pupils' failures, so we cannot suggest any curriculum changes, based on the analysis of this question. Nevertheless, we did point out to teachers, that they should find out how their pupils managed this problem. If they find out that their students failed because of the unit conversion, they should pay more attention to unit conversion. Similarly, if the failure was mainly a consequence of not knowing how to calculate the volume of the aquarium, the physics teachers should consult mathematics teacher in order to see how and when the pupils learn about that formula. Further, the teachers should adjust teaching, so that this topic is treated after the time the pupils learn this formula. But all this advises are not directly related to curriculum change.

CONCLUSIONS

The national assessments of knowledge of physics provide valuable data on the state of knowledge of physics among the pupils at the end of their elementary education at age around 15. Coherent results (Figure 1 and Table 1) and similar general findings, such as lack of ability to solve structured problems or good results when answering simple reproductive questions, indicate that the assessment as a measuring tool is working fine. Nonetheless, for various reasons, such as only two measurements in 2007 and 2008 and limited number of problems related to a specific topic, it is not possible to predict the effect of particular curriculum changes on the knowledge gained, let alone acquired competences. As we have shown by a few examples, interpretation of the results allows too much freedom to justify this or that particular change in the curriculum. In other words, national assessment is designed to measure the knowledge and it shall detect the change of knowledge, should there be one, but it is not at all certain, that the analysis of the assessment tests will reveal the connection between the curriculum change and the change of knowledge of physics. Last but not least, in order to reasonably adjust the curriculum, some studies relating the methods of teaching to the knowledge gained by the pupils should be done in addition to the existing assessments of knowledge of pupils.

ACKNOWLEDGEMENTS

All the data used in the paper have been collected and statistically analysed by the National examination centre (RIC – Državni izpitni center, (http://www.ric.si)). The assessment tests were prepared by Branko Beznec, Uroš V. Brdar, Vinko Udir, Ivo Verovnik, Zlatka Ferlinc, and Jure Bajc.

FIRST YEAR UNIVERSITY STUDENTS' CONCEPTIONS ABOUT CELL

Barbara Bajd

University of Ljubljana,

Faculty of Education

barbara.bajd@guest.arnes.si

ABSTRACT

Some teachers have voiced concerns that knowledge and understanding of biology, especially about cell structures and mechanisms, is not sufficient in upper secondary school because there not enough hours in the curriculum are devoted to biology teaching. Some teachers have even advocated that 'the cell' should be taught in primary school. Too detailed teaching about cell structure and mechanism with excessive data can be reflected in poor understanding and a lack of basic knowledge about cells and cell mechanisms. Our investigation showed that students of the first year at the Faculty of Education (after finishing upper secondary school) do not have enough basic knowledge about cell structure and its major inclusions. The reason is not a lack of hours in the curriculum for biology, but rather the approach to teaching basic biological knowledge.

Keywords: *cell, students' conceptions about cell structure, misconceptions*

INTRODUCTION

The 'Cell' is a largely abstract notion for primary school pupils, and so in Slovenia cell structures and mechanisms are not taught until upper secondary school. All pupils who have completed upper secondary school have had at least 15 hours devoted to cell structures and cell mechanisms, and in some schools that time has more than tripled to (47 hours). Students are expected to know about organelles (such as plastid, vacuole, mitochondrion, Golgi apparatus, lysosom, endoplasmatic reticulum, ribosome, cilia and flagella, centrioles, nucleus, cell wall and plasma membrane) as well their functions. So we might expect that students entering the first year at university would have appropriate knowledge about cells and cell mechanisms. We consider that the current teaching allocation in upper secondary school provides sufficient time for pupils to acquire information about cell structure and function, and extending the time allocated within the curriculum will not improve that knowledge. It will be far more effective to change the teaching approach to the topic to produce better understanding by pupils. Some investigations show that within biology intrinsic motivation is higher for learning concrete contents (e.g. the human body, systematics, ecology) rather than more abstract ones (e.g. microorganisms, cells genetics) (Juriševič et al. 2010). A knowledge of cell structure is a necessary prerequisite for effective understanding of cell processes and their functions. The purpose of our study was to assess the conceptions and understanding of cell structure among students in the first year at the Faculty of Education, University of Ljubljana.

METHOD AND RESULTS

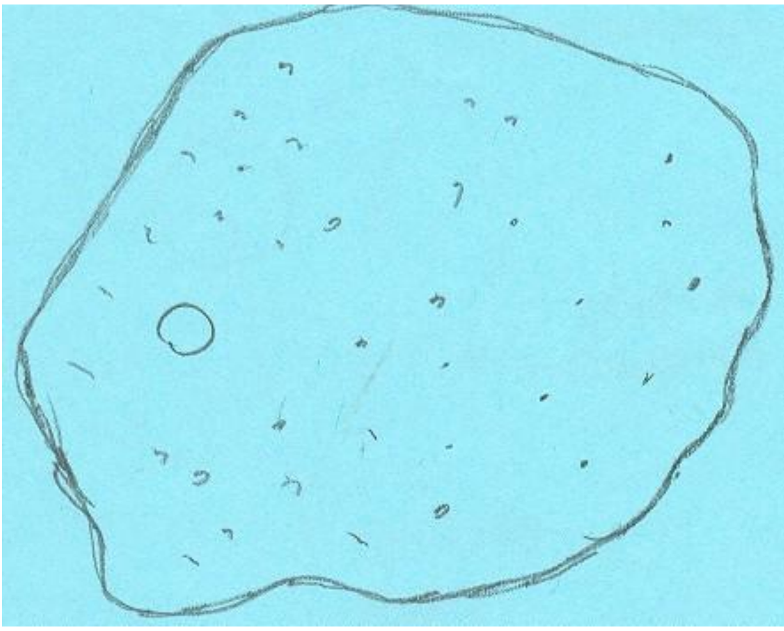
The categories of student included in our survey reflect the structure of education and teacher training within Slovenia: we questioned 96 primary school students (training to teach children aged 6 -10 years) and 47 preschool students (training to teach children aged 0 - 5y years) for this study. We asked them to draw a cell and its internal structures, and to label them, since we wished to know which organelles they still remember from upper secondary school. (At this point they had not had any teaching on cells and cell structures within the Faculty of Education). We planned to use the results as the starting point for a lecture on cells in science lessons at the Faculty. Before they started to draw, students of primary school teachers asked if they have to draw an animal or plant cell, while preschool teacher students did not put this question. We collected students' drawings and analysed them. Three primary school students drew plant *and* animal cell, the rest of the students had drawn *either* a plant *or* animal cell. Plant and animal cells differ in some organelles: plant cell contains a cell wall and chloroplasts, but animal cells lack these so those drawing animal cells could not include these, and we have therefore omitted them from the following analysis and discussion. The results indicating which organelles primary school students (RP) and preschool students (PV) mentioned are presented in table 1.

Table1. Cell organelles and cell structures mentioned by primary school (RP) and preschool (PV) students.

	N	C	P	GA	ER	M	R	Nc	C	L	Cit.
RP	96%	89%	34%	22%	9 %	55%	11%	9%	2%	1%	1%
PV	87%	21%	40%	9 %	2%	19%	4%	-	-	-	-

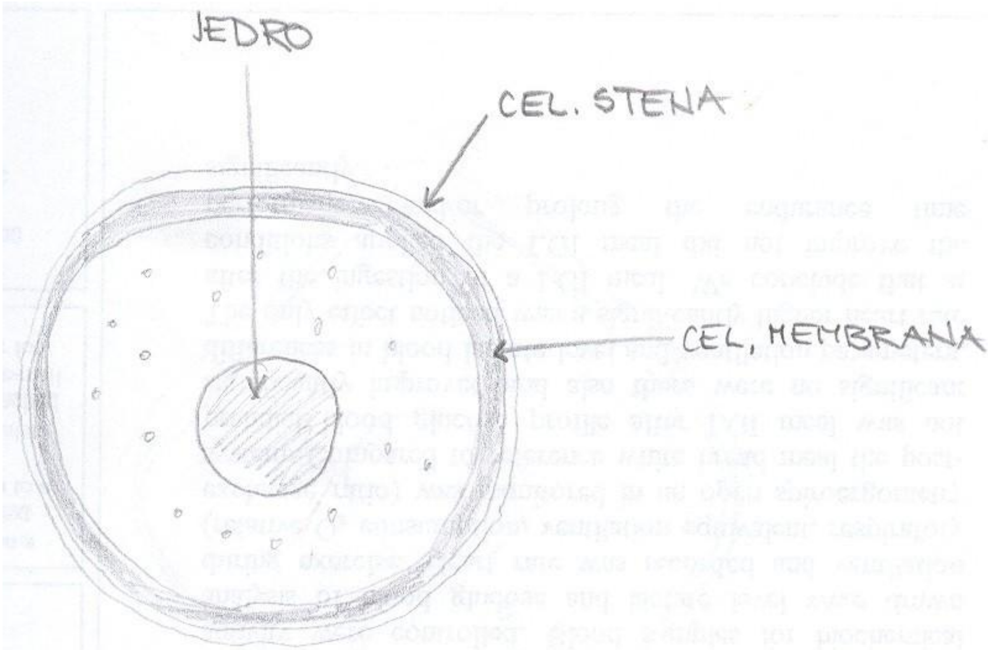
N- Nucleus
C- Cytoplasm
P- Plasma membrane
GA- Golgi apparatus
ER-Endoplasmatic reticulum
M- Mitochondrion
R- Ribosome
Nc- Nucleolus
C- Centriol
L- Lysosom
Cit- Cytoskeleton

We also analysed the students' drawings, which differed a good deal. Some were very simple and lacked explanation (see, for example, picture 1). As we can see from this picture, the preschool teacher who drew it had in mind that there are some structures within the cell, but she did not know their names, including that for the large circle, which probably represents the nucleus.



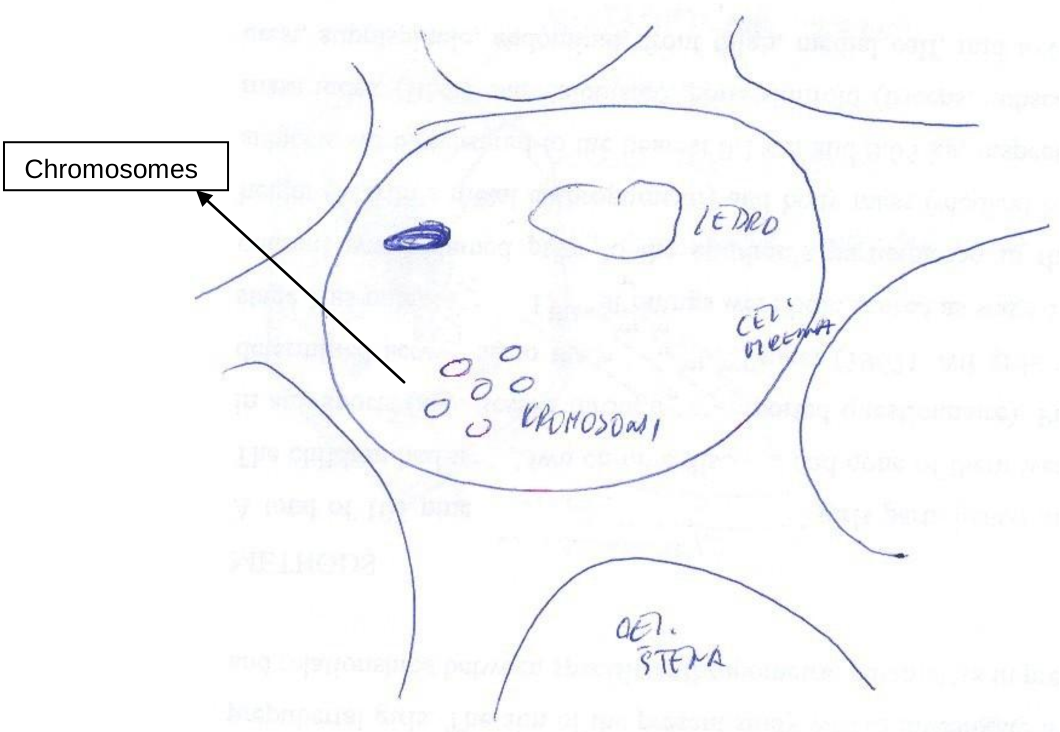
Picture 1: Drawing of the cell without named structures

The majority of students drew the cell as represented in picture 2, with a nucleus and plasma membrane, and in plant cells they also drew the cell wall. Some pre-school students drew the cell and some internal structures, but they could not name them, or named them incorrectly.



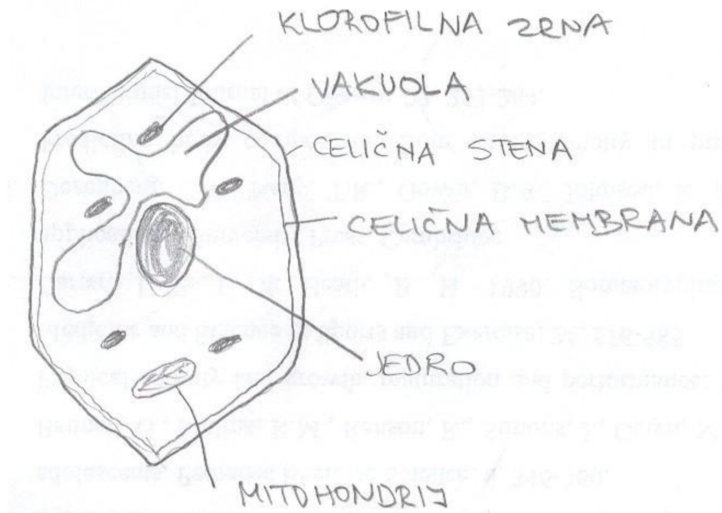
Picture 2: Drawing of the cell and some internal structures. Some are named and some not.

In picture 3 we can see that the student drew the chromosomes in cytoplasm outside the nucleus, indicating that she is unaware that chromosomes or DNA are situated within the nucleus. The black spot probably represents a mitochondrion.



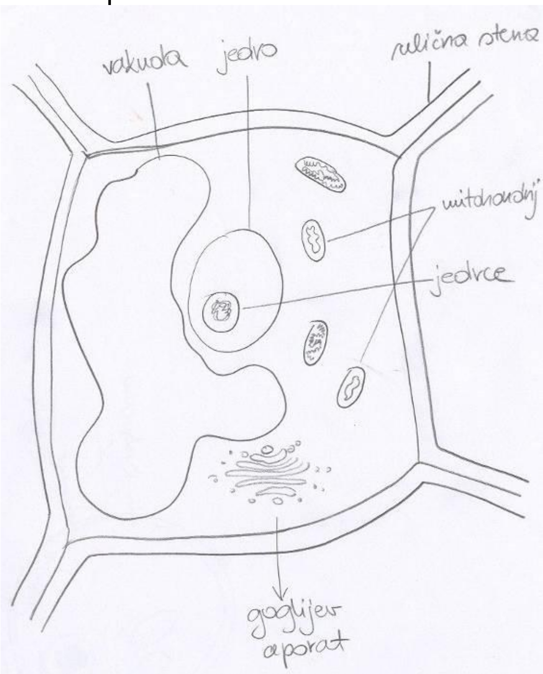
Picture 3: Drawing of the cell where chromosomes are situated out of the nucleus.

Picture 4 presents a good picture of a plant cell, with nucleus, mitochondrion, chloroplasts vacuole, plasma membrane and cell wall, drawn by a pre-school student teacher. Only one of the pre-school teacher students drew and named the endoplasmatic reticulum. We do not know whether the student meant an agranular or granular endoplasmic reticulum, and she has drawn it away from the nucleus, indicating she is unaware that granular endoplasmic reticulum is connected to the nuclear membrane. Very few pre-school teacher students drew the Golgi apparatus (9%) or ribosomes (4%), and none of them drew the nucleolus, centriol, lysosome or cytoskeleton.



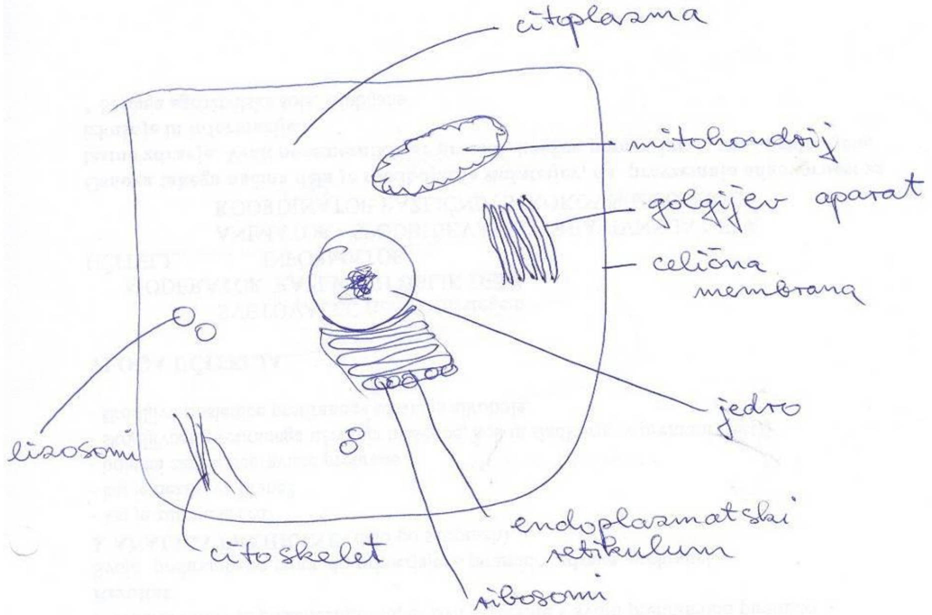
Picture 4: Drawing of a plant cell, with nucleus, mitochondrion, chloroplasts vacuole, plasma membrane and cell wall, drawn by a pre-school teacher student.

The primary school teacher students drew the cell with more details and cell organelles. They also drew the nucleolus (picture 5), which none of pre-school teacher students drew. A greater proportion (55%) of primary school teacher students also included mitochondria in their drawings compared with the pre-school teacher students.



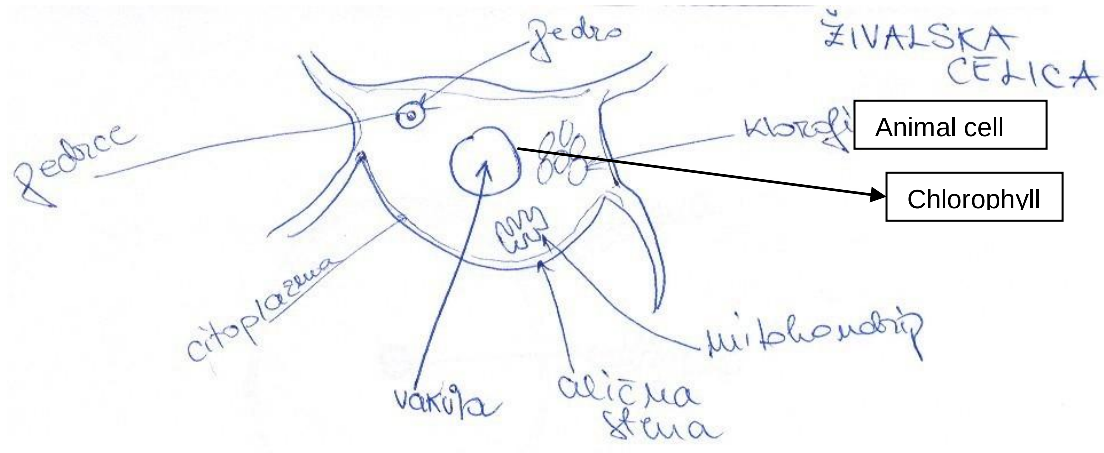
Picture 5: Drawing of the cell with more details and organelles

Greater numbers of primary school teacher students (89%) also marked the cytoplasm in the cell (picture 6) compared with pre-school teacher students, and one also drew lysosomes and the cytoskeleton. Those who draw the endoplasmic reticulum drew it in connection with nuclear membrane, or even drew ribosomes on it. But the majority of those who drew ribosomes placed them within the cytoplasm and not on the endoplasmic reticulum.



Picture 6: Drawing of the cell with lysosome, granular endoplasmatic reticulum and cytoskeleton

Picture 7 represents the animal cell. The student who drew it probably did not know the difference between animal and plant cells since she drew and marked both chlorophyll and a cell vacuole. It is probable that the student did not know the function of chloroplasts, and that they and the contained chlorophyll are the main characteristics of green plant cells.



Picture 7: Drawing of animal cell with chlorophyll

CONCLUSIONS

This investigation was prompted by a growing awareness among Slovenian science teachers that students' understanding of cell biology was more limited and less effective than that of other areas of the science syllabus, leading to a general debate about the nature and extent of teaching these topics within the secondary school curriculum. Some teachers have argued that there is insufficient time allocated to teach the complex concepts involved, so pressing to expand the time available at the expense of other topics. However, an alternative interpretation is that it is not the time available but the design of the lessons and approach to teaching the subject that militates against students' effective understanding.

The results presented here indicate that despite the fact that every students in upper secondary school has been taught about cells, cell structures and organelles, their recalled knowledge is very limited. We asked them only to draw the cell organelles, and not to list the functions and mechanisms of organelles. As noted earlier, an acquaintance with cell structure is a necessary prerequisite for any understanding of metabolic processes. Moreover, since cell structure is concerned with knowledge of specific objects (nucleus, vacuole, mitochondrion etc) for the great majority of school students it is easier to understand than the more diffuse and theoretical concepts of cellular processes and their functions. Had we asked our students questions on cell mechanisms we therefore think that we would probably have been presented with even more limited knowledge. We plan to test this supposition and to investigate aspects of students' understanding of cell processes and functions in further surveys.

We can see from our results that the majority of students knew that the cell has a nucleus, but nobody mentioned or drew a bacterium cell or human red blood cells which are exceptions to this generalisation. Cytoplasm was mentioned much less by the preschool teacher students than by the primary school students, with only one fifth of preschool teacher students and nearly 90 % of primary school students marking the cytoplasm. The results indicate that intending primary school teacher students had much better knowledge of cell structures than pre-school teacher students. For example, mitochondria were mentioned by more than half of the primary school students, while less than a fifth of pre-school teacher students mentioned these structures. If they are unaware of mitochondria they will not understand their function, and so are unlikely to know that plant and animal cells contain organelles that are responsible for cell breathing (Hersley, 2004). This further confirms the findings of another investigation we undertook in our faculty that 14% of students still fail to realise that breathing and photosynthesis are two different (opposite) processes, although they were taught that in their first year of study at the Faculty. The main function of mitochondria is the conversion of energy stored in carbon-containing molecules, especially glucose, into high-energy bonds of ATP, which is the only usable energy source for many cellular activities. This basic fact should be known by every teacher student, whether intending to be a preschool or primary school teacher.

We provisionally conclude that, despite many hours (20-47 hours depending on the particular programme) spent teaching cell structure and function in the upper secondary school curriculum in Slovenia, students do not have enough basic knowledge of cell organelles and structures. We take the view that there is currently enough space within the biology timetable to provide students with the relevant basic knowledge of these topics. Rather, the problem is that students have to learn too many details and do not focus on the basic information required to understand the fundamental mechanisms of the living world. With so many facts and so much information having to be memorised for pupils to achieve a good mark, they loose sight of the main points, and fail to see the wood for the trees. So teachers should be selective in the subject detail they provide, and plan carefully what and how much to teach about cell topics so that pupils thoroughly understand the most fundamental aspects of the structure, mechanisms and functions of cells. We intend to explore further aspects of students' understanding of cell structure, processes and functions in future surveys, and to consider in detail their implications for the design of lesson plans, curriculum materials and learning resources for these topics.

ABSTRACT

This investigation is a case study based on a teaching situation developed to help 8th-grade students build a physics model for the additive synthesis of colored light. Devised within a research development group, the teaching sequence integrates the use of free downloadable simulation software and the handling of real teaching materials. The data collected consisted of video recordings of a group of students and their teacher, with partial multimodal transcriptions. Excerpts of the transcriptions were analyzed by identifying the points of view held by students and teacher on the comparison of simulation and practical experiments. The evolution of these points of view and their discussion by the participants were examined from a theoretical perspective, allowing the classroom discourse to be analyzed. Concurrently, the bridging of the two competing models derived from separate teaching cultures—i.e. the visual arts and physics—was discussed from a modeling perspective. Common sense knowledge or visual arts terms used by the students were found to interfere with physics-specific knowledge and terminology, revealing underlying concept misunderstandings and factual misconceptions.

Keywords: *optics, models, color.*

INTRODUCTION

This investigation is rooted in the many years of experience of our research teams—which are investigative groups founded on a collaborative effort of practicing teachers and researchers—in designing physics and chemistry teaching sequences for use in upper secondary schools. One of our central hypotheses is that modeling activities carried out by students are, from an epistemological point of view, related to the mode of construction of physics concepts (Bécu-Robinault, 2002).

In addition, other theoretical underpinning aspects were taken into account, addressing the role of social interactions in learning and the role of misconceptions in the process of learning and teaching described in science education research. In this perspective, a range of teaching-learning sequences have been developed, implemented in classrooms, and evaluated. Our first learning objective addressed the discussion of a model capable of allowing students to interpret colors obtained by superposing several colored lights. The second objective was to make the modeling process underlying a software-based simulation explicit. This paper focuses on the interaction between 8th-grade students and their teacher during an activity involving additive color synthesis aided by simulation software (Visiolab[3]) and practical experiments.

[3] The software can be downloaded from ftp://ftp.discip.crdp.ac-caen.fr/discip/phch/college/quatrieme/visiolab.zip

THEORETICAL FRAMEWORK

We selected a theoretical framework capable of encompassing social interactions occurring in the science classroom. Viewed in this light, learning is the result of a negotiation of new meanings. The classroom context can be characterized by the status of its actors: the teacher presents a clear-cut point of view (that of school science discourse), whereas the students have their own points of view, albeit not always well thought out and differing from one student to another—and even more often from the teacher's view. Generally, the teacher's point of view is assumed to be accepted by all students by the end of the lesson. In order to enable the students to discuss the validity of pieces of cultural knowledge originating from different cultural backgrounds, the teacher has to negotiate the introduction of this range of points of view during the class. The manner in which the teacher organizes the confrontation of differing points of view is an important element in the analysis of speech in the classroom. To this end, Mortimer and Scott (2003) addressed the communicative approach by considering communication in its various dimensions. They concluded that communication can be described as "dialogical" if the teacher takes into account the variety of points of view stated by the students; conversely, it is described as "authoritative" if the teacher takes into account only the point of view of the school knowledge. The "dialogical" versus "authoritative" dimension is independent of the number of individuals in interaction. Mortimer and Scott also proposed a second dimension: "interactive" or "non-interactive." A given approach is described as interactive if more than one person takes part in the discourse, and as non-interactive when discourse is limited to one student. These investigators claim that alternation between authoritative and dialogical approaches facilitates the learning process.

Scientific discourse is characterized by specificities. Kress et al. (2001) demonstrated that learning to talk about sciences at school goes beyond verbal aspects. The scientific discourse is multimodal and uses multiple semiotic registers (Duval, 1995). Learning science implies the appropriation of concepts, instruments, and cultural practices by a multimodal language (Lemke, 1990). Interactions in science classes are therefore organized with a plurality of multimodal resources, including gestures, glances, body postures, movements, and questions and answers from students and teachers alike, and also involve the handling of objects, texts, charts, sketches, diagrams, and lists of number, in addition to the use of simulations and other procedures.

MODELING ACTIVITIES

The effect of the information conveyed by the written instructions accompanying a simulation device and furnished orally by the teacher during the modeling carried out by students also has to be examined (Bécu-Robinault, 2002). While performing modeling activities, students establish relationships between two levels: the level of theories and models and that of objects and events. For instance, while describing an experimental situation such as a lamp that shines, students will be addressing the level of objects and events. On the other hand, while interpreting or predicting what occurs in terms of current or energy, they will be dealing with the level of models and theories. Learning physics implies learning how to integrate both levels (Tiberghien, 1994).

In the situation investigated in this paper, two color models from distinct cultural and teaching domains can be mobilized in the discourses of students and teacher. The model that the teacher aims to introduce is the physics model of additive color synthesis, which considers color as light. The second model, usually taught in visual arts courses—and also found in everyday life—is grounded in subtractive color synthesis and requires color to be viewed as matter, not light. An analysis of the current French official visual arts curriculum reveals that the subtractive synthesis model has previously been taught to 8th-grade students, allowing them to interpret or predict phenomena on the basis of either the color-as-light model or the color-as-matter model, in association with terms that refer to one of these models or even terms referring to both models. In fact, some of these terms, such as color names, can be ambiguous. When a determiner precedes a color name, the name tends to be implicitly interpreted as relating to the color-as-matter model. When preceded by the determiner "light," the color-as-light model is evoked. The term "mixing" tends to evoke the color-as-matter model, rather than its color-as-light counterpart. A more appropriate term for light syntheses would be "superposition."

With these elements in mind, our purpose was to analyze the discourses taking place in the classroom in terms of modeling levels and competing reference domains.

RESEARCH QUESTION

In the context of this theoretical background, the purpose of the present investigation was to investigate the role played by a teaching sequence and the interactions attendant on the verbal, written, and simulation activities proposed to interpret phenomena related to the superposition of colored lights and to facilitate the construction of an underlying physics model by middle school students.

METHOD

CHARACTERIZING THE INVESTIGATION: DATA COLLECTION AND CORPUS ANALYSIS

A qualitative methodology suitable for case studies was selected for this investigation. Video recordings and partial multimodal transcriptions of the discussions held by three students (herein given the fictitious names Chuck, Nick, and Julia) were made before and after using the Visiolab simulation software. The teacher's discourse was also recorded. Handouts distributed by the teacher and completed by the students were collected for analysis. Physics and visual arts curricula were used as references to analyze cultural knowledge.

ANALYSIS OF THE TEACHING SITUATION: THE TEACHING STRATEGY

In a preliminary activity, students produced colored lights using color filters and a conventional light bulb (data not shown). Subsequently, and with the purpose of collecting data for the present analysis, the students were asked to predict the light color obtained by mixing two (or three) of the following colored lights: blue, red, and green. Subsequently, they were asked to compare their predictions with the results of the software-based simulation. Finally, the teacher asked them to reproduce the simulated experiment using devices generally available in the physics classroom.

Before attending this physics course, the students were familiar with the color model taught in visual arts classes—i.e. the subtractive color synthesis model. In this physics class, they were supposed to use the physics model of additive color synthesis.

A PRIORI ANALYSIS OF THE SITUATION

THE WRITTEN INSTRUCTIONS

The students were given a table to complete with answers on the predictions made before using Visiolab and with the results achieved in the simulation. They were initially asked to name the colored lights obtained by superposition and to fill in each corresponding box with color pencils. These instructions introduce ambiguity with regard to the model they are to use. On the one hand, they have to think about superposing colored lights; on the other, they are asked to represent these lights by coloring a box with pencils to indicate the color of light obtained. These two types of activity may legitimize the mobilization of two cultural models—one from physics, one from the visual arts—by the students.

In France, the official visual arts curriculum states that the subject "colors" should be taught in the 7th grade: "paints are color and matter. […] the color is substance and light, material and immaterial. This is perceived immediately by the observer. […] The student will discover the color spectrum and some of the color organization systems created by painters. While the students learn how to select and blend colors, they should be allowed to experience the sensory, representative, symbolic system and its expressive potentials" (B.O., 2008).

ONE CONCEPTION HELD BY STUDENTS: THE NATURE OF COLORED LIGHT

In everyday language, when someone says "the book is red," color is considered as an innate property of the object. This interpretation comes from intuitive knowledge, yet is incompatible with scientific conceptions (Anderson, 1986). Many studies show that students explain color believing it to be a property of objects (Anderson, 1986; Drive, 1989; Bravo, 2005). Students' explanations are generally built as simple causal relations based on common sense observation. Other conceptions, reported by Feher and Meyer (1992, in Bravo, 2005, p. 341), include colored light viewed as dark and containing color that can be mixed with that of the object. Driver et al. (1989) found that students aged 10 to 15 years usually do not spontaneously relate color to light.

ANOTHER CONCEPTION HELD BY STUDENTS: FILTERS AS COLOR AND LIGHT SOURCES

Investigating students aged 12 to 15 years on their conceptions about the role of filters, Anderson and Kärrqvist (1983, in Bravo, 2005, p. 340) found them to believe that light changes when interacting with a filter, becoming colored by getting color from it. In some situations filters are treated as sources of light and not as materials in which absorption and selective transmission of light take place (Chauvet, 1996).

THE SOFTWARE

When Visiolab is started, three colored circles (red, blue, and green) are superposed on a black background (Figure 1, left). Three colored projectors are depicted at the bottom of the screen. The students can move the lights by dragging the circles, and the orientation of the projectors will change accordingly (Figure 1, right). Although the simulation should address only the physics model, the screen shows circular areas of solid color, but not beams of colored light.

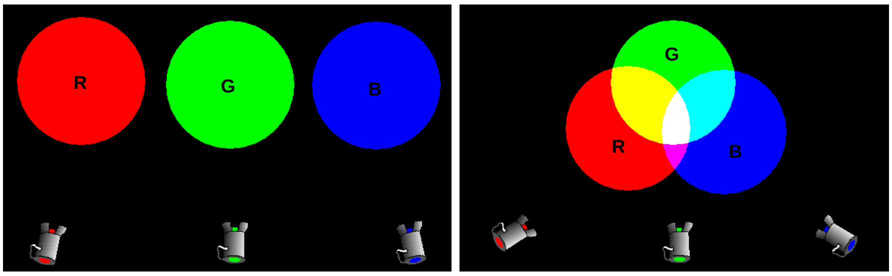

Figure 1: Screen captures using Visiolab software (G: green light; B: blue light; R: red light). White light is visible at the intersection of the three circles.

Operation of this software leads the user to concentrate on the colored circles, not on light emitted by the projectors, and therefore tends to legitimize the mobilization of the visual arts model, even though the results are in accordance with the additive synthesis model.

DESCRIBING AND ANALYZING THE TEACHING SEQUENCE

The tools applied here to analyze interactions and meaning-making in science classes are mostly based on Mortimer and Scott (2002), who proposed an analytical tool consisting of five aspects: "communicative approach," "teaching purposes," "content," "teacher interventions," and "patterns of interaction." The focus is on the teacher's work to introduce and discuss scientific ideas or knowledge regarding the variety of points of view put forward by the students.

Another important aspect to be analyzed is the process of knowledge construction. From an epistemological point of view, science describes phenomena using theories and models. These theories and models allow events to be explained and predicted. From an educational point of view, students are accustomed to the world of objects and events. Representing this world by a model implies an interpretation that students have to apprehend. Generally, teachers do not dedicate much attention to making the difference between the world of objects and events, and the world of models and theories explicit (Buty & Mortimer, 2008). To analyze how the color model of physics is discussed in the science classroom, we also used another analytical tool, based on the categories introduced by Silva and Mortimer (2007a). We chose categories from both analytical tools, according to our research interests. In doing so, an analysis grid emerged (Table 1).

RESULTS AND ANALYSIS

The following sections describe and analyze three of the six episodes in this lesson. Each episode corresponds to a segmentation resulting from the tasks proposed in the labwork sheet or defined by the organization of classroom work by the teacher.

Table 1. Analysis grid and definition of the analyzed aspects

Analysis criteria	Definition of aspects
1 Teaching purpose	Teachers' actions to develop ideas and knowledge in the classroom
2. Communicative approach	▪ Interactive or non-interactive ▪ Dialogical or authoritative
3. Teacher's interventions	Form of intervention to develop teaching content
4. Students' actions	▪ Epistemic actions performed by students (description, explanation, classification, …) ▪ Types of reference (concrete, abstract) ▪ Modeling activities (objects/events, theories/models)
5. Patterns of interaction	Types of alternation in the discourse between teacher and students

In the first episode, the teacher explains the tasks to be performed by the students and rephrases the written instructions. The task involves switching on several colored lights to produce colored environments. The second episode corresponds to the prediction phase (Table 2). In the third episode, the students use the software to collect information on the results obtained from superposing colored lights. Even when the software fails to yield results compatible with the predictions, the students do not express any surprise. The rare discussions taking place among students during this phase address the terminology of the colors visualized in the simulation, but not terms referring to the colors of light. The students designated colors using everyday terms (pink, celestial blue) and did not refer to the color names previously taught in visual arts classes (magenta, cyan). The fourth episode involves discussion of the results achieved using Visiolab in comparison with predictions (Table 2). In the fifth episode the students discuss the possibility of carrying out real experiments. At this point the teacher engages in a negotiation of the concepts to be used: colored lights and not colors: color superposition and not color blending. He manages to ask each group some questions, repeating most of the answers he received. This repetition by the teacher can be interpreted by students as a validation of their answers. The analysis shows that students still do not differentiate between color-as-matter and color-as-light models. The sixth episode evolved from the teacher's wish to engage the classroom in a debate on the experiments proposed by the students (Table 2).

Table 2. Summary of the analyzed episodes

Analysis criteria	Selected episodes		
	2. Prediction task	**4. Discussion of simulation results**	**6. Comparison with practical experiments**
Teaching purpose	▪ Formulate and write down predictions on the colored light obtained when two or three colored lights are superposed	▪ Compare students' predictions and results of a virtual experiment (Visiolab) ▪ Propose an experiment using the materials and knowledge gained in previous lessons	▪ Allow students' conceptions about colored light to emerge ▪ Carry out an experiment with colored lights ▪ Compare observed phenomena with results achieved in the simulation
Communica-tive approach	▪ Non-interactive/dialogical	▪ Interactive/dialogical ▪ Interactive/authoritative	▪ Interactive/dialogical
Teacher's interventions	▪ Teacher does not intervene, but observes the students while allowing them to discuss in small groups	▪ Teacher asks students to compare their predictions with virtual experiments, encouraging them to find arguments to justify the validity of their predictions ▪ Teacher asks students to talk about the possibility of obtaining the same result with materials usually available in the classroom. He proposes they draw a diagram.	▪ Teacher asks students to compare their predictions with the simulation results and to find arguments to explain the validity of their predictions
Students' actions	▪ Epistemic actions by students: explanation and prediction ▪ Types of reference: concrete and abstract ▪ Modeling activities: objects/events	▪ Epistemic actions by students: explanation and prediction ▪ Types of reference: concrete and abstract ▪ Modeling activities: objects/events	▪ Epistemic actions by students: explanation and prediction ▪ Types of reference: concrete and abstract ▪ Modeling activities: objects/events
Patterns of interaction	▪ Discussion among students	▪ Discussion between students and teacher	▪ Discussion between students and teacher ▪ Students present their ideas to the whole class

EPISODE 2: PREDICTION ACTIVITY

In this activity, the students are supposed to formulate and write down predictions concerning the colors obtained, based on previous knowledge. While putting forward their predictions, the students are not actually convinced of their validity. One student, Chuck, makes a prediction based on the color-as-light model: "red and green, that's yellow." Faced with his partners' doubts, he is unable to find any argument to support his view. The following excerpt exemplifies the interaction held between the students while predicting the colored light to be obtained by mixing red and green lights:

Nick: Let's write green. Go ahead!
Chuck: But it won't be green if it's red and green.
Nick: Yes, it will.
Chuck: It will be yellow […].
Julia: Red and green, doesn't that make brown?
Nick: Oh, yes!

The excerpt shows that students shift from the visual arts model (Nick thinks that green and red can produce a type of green) to the physics model when Chuck proposes that the answer is yellow. A few seconds later, Julia reintroduces the visual arts model while posing a question, and proposes “brown.” Because this answer is culturally well-established, Nick and Chuck promptly agree. The group carries on predicting the next resulting colors, using the color-as-matter model. Nevertheless, their agreement seems quite fragile, as if they were not fully convinced; in fact, every answer is either preceded or followed by unenthusiastic phrases such as “Okay, let’s write red.”

EPISODE 4: DISCUSSION OF SIMULATION RESULTS

As the students superpose colored circles on the Visiolab screen, they note down the resulting colored lights on a labwork sheet without questioning these results. The fact that superposing green, blue, and red light yields white light does not seem to draw their attention or surprise them in any way. More strikingly, they do not compare this result with the fact that blending colored pencils does not yield white. The only aspect the students observe using the simulation software is the influence of the order of superposition. During this discussion, one student evokes a previous lesson and introduces a filter to produce colored light. Nick is the first to express his point of view, being promptly supported by Chuck. Nick proposes using a white filter, i.e. a filter thought to be equivalent to the combination of blue, red, and green filters. This argument is based on the software simulation, in which the combination of red, green, and blue light yields white. The group seems to reach an agreement on this first point of view, and they all proceed to write down this answer. Just as they start writing this down, the teacher approaches. A very rich discussion follows, providing an overview of the difficulties of teaching and making sense of the superposition of colored lights. The discourse analysis reveals that common sense knowledge interferes with physics-specific knowledge, as shown by the frequent undue use of visual arts terms in place of physics terminology, revealing underlying concept misunderstandings and factual misconceptions.

As soon as the students seem to have reached consensus, the teacher asks them, “Do you agree?” and begins to move away from the group. The increase in physical distance between teacher and students, reinforced by mimics (a finger on his mouth, Figure 2), is perceived by the students as a sign that the first point of view expressed may not be correct. The teacher’s stance is paralleled by the distance between the students’ point of view and his own. By keeping the students at a distance, the teacher shows that he does not support their point of view.

Figure 2. The teacher stands back from the group (and from their point of view)

The teacher then glances at the three students to make sure they are actually in agreement. He focuses on Julia, who obviously holds another point of view (she shakes her head). The teacher then helps her to express her idea, pointing at her, and coming closer (Figure 3):

Teacher: You’re not convinced.
Julia: No, this is going to produce color.

This change in the teacher’s stance indicates that he is open to new ideas and that the new point of view might be closer to his own.

Figure 3. The teacher points to Julia and draws closer to her (and her point of view)

The students start a new discussion and try to find arguments supporting the new point of view. The teacher observes the group until the discussion comes to a close. Chuck proposes using three colored lights (not three colored filters). The teacher moves closer to Chuck and fixes his gaze on him, thus showing that what is being formulated is crucial. Before Chuck is able to explain how it would be possible to arrange the three lights, the teacher mimics the different spatial positions of these lights and the way the beams meet each other (Figure 4).

The teacher then concludes with "Are you all agreed now?" and moves ahead to another group. This stance is interpreted by the students as an indication that the correct answer is under construction. A final argument is found by Chuck to validate this point of view in relation to the simulation software.

Figure 4. The teacher mimics the way the beams of colored light will meet (shown from left to right: green, blue, and red)

At this point, Nick agrees to change his mind:

Chuck: There are three projectors on the computer.
Nick: Yeah, three different filters with three different projectors.

From a modeling perspective, the analysis of the students' discourse shows that as they proceed in the production of their answer, they keep treating the colored lights they are superposing and the resulting colors obtained as if they were paints.

Nick: Earlier we saw the three make white.
Chuck: We should project a green color, a blue one, and a red one.

The terms "light" and "colored light" are rarely present in their discourses. This absence prevents the activation of the physics model and strengthens the mobilization of the visual arts model. At the end of this episode, we noted, to our great surprise, that the final answer the students chose to note down (Figure 5) did not take into account the previous discussion. Instead, they stuck to their initial point of view—i.e. regarding the white filter as equivalent to a combination of green, red, and blue filters. Moreover, the white filter they proposed is represented with white paint. This answer shows that a strong ambiguity still remains between the two models.

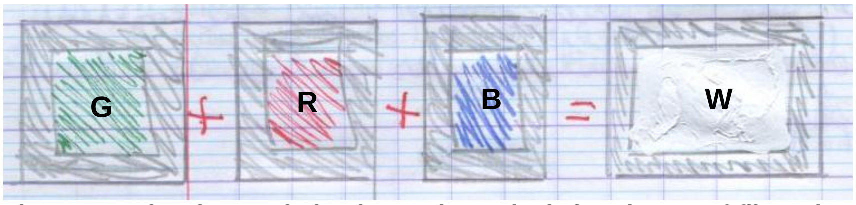

Figure 5. A drawing made by the students depicting the set of filters (G: green; R: red; B: blue) used to produce white (W) light.

EPISODE 6: PROPOSED COMPARISONS WITH PRACTICAL EXPERIMENTS

The teacher begins this episode by recapitulating on the proposals put forward by the groups on how to reproduce the simulation using real materials.

Two types of answer are given to reproduce the simulation using materials generally available in the classroom (Figure 6). The first proposal requires the combined use of three filters; the second makes use of three white light sources, each equipped with a colored filter.

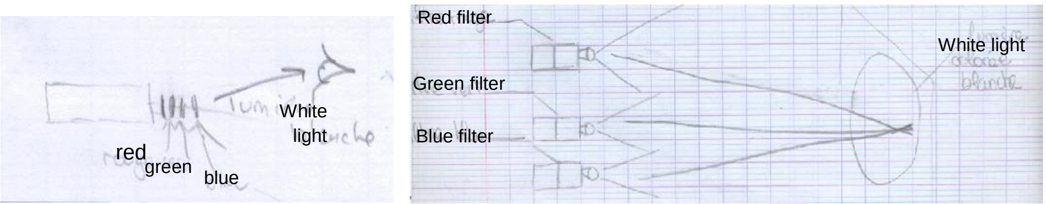

Figure 6. Drawing made by students to depict a simulation based on available materials. On the left, three color filters are associated, producing visible white light; on the right, three colored beams produce white light.

The teacher engages the classroom in a debate on the experiment that might adequately reproduce what has been achieved in the simulation. After debating the availability of material, a discussion starts on what might be observed upon superposing the three filters. At this stage, a student deploys sequential causal reasoning: as light goes through successive filters, it is gradually transformed, so that white light going through a red filter becomes red light, then while going through a green filter it becomes green, and so forth. The point concerning the final transformation into white light is left open. This sequential reasoning seems to be coupled with another understanding of filters: that colored filters might behave like filters used in chemistry classes to change muddy water into clear liquid.

During this episode, students still feel uncomfortable with the presence of two competing models. These difficulties are reinforced not only by the representation of colored lights that students are required to make in their notebooks, but also by the teacher's representation of these lights on the whiteboard. In fact, to represent colored light one must make use of paints or color pencils. Utilization of these tools legitimizes the fact that both the students and the teacher make use of the color-as-matter model.

> Teacher: We're going to draw three small circles: a blue circle, a red circle, and a green circle. In fact that's red-, green-, and blue-colored lights.

In the classroom discourse that follows, the two models are mixed. Both the teacher and the students, through their use of verbal shortcuts and common sense terms, spontaneously mobilize concepts favoring the color-as-matter model. The teacher speaks about "adding lights" (in reference to the additive synthesis) instead of superposing lights. In everyday language, this addition corresponds to the blending of colors as matter.

In the following excerpt, all terms referring to color-as-matter are underlined, references to color-as-light are boldfaced, and color names or other terms that are ambiguous with regard to the model are in italics. Translation required that color names be specified between square brackets as nouns (color-as-matter) or adjectives (ambiguous):

Teacher: We've said that when *adding* **blue-colored light** and **green-colored light** when we *add* **blue-colored light** and **green-colored light** we obtain <u>a blue</u> [noun] that is called *the blue* [adj.].
Nick: *Cyan.*
Teacher: *Cyan.* So we write there cyan […] when we *add* **red-colored light** and **green-colored light** we obtain…
Student: <u>Yellow</u> [noun].
Teacher: **Yellow-colored light** / so <u>yellow</u> [noun], I do not have a <u>yellow pen</u> / so I'm going to write *yellow* / when we **superpose red-colored light** and **blue-colored light** we obtain *a color* that has a particular name...
Nick: *Magenta, magenta.*
Teacher: <u>Magenta</u>. We're going to write M and when **we superpose blue-colored light** and **red-colored light,** and **green-colored light**, **the three colored lights** together, it produces…
Student: <u>White</u> [noun].
Teacher: It produces **white-colored light** / is it the same thing with <u>paints</u>?

At the end of this excerpt, the teacher draws a parallel between what is obtained by blending paints and what is obtained by superimposing colored lights. In French, the words used are the same (mixing). This terminology is confusing and does not help to choose the appropriate model. This episode ends when the teacher states that "paint is matter" and that it is possible to touch paint but not light.

CONCLUSION

The integration of two competing models—the physics model (additive synthesis) and model of visual arts (subtractive synthesis)—is not simple to manage in the classroom. In the situation analyzed here, both models were implicitly invoked. Ambiguity in the legitimacy of each model was unfortunately introduced in the labwork sheet instruction and in the simulation task. Through the dialogical and interactive dimensions of the communicative approach, the teacher attempted to negotiate the exclusive use of the physics model, but his recourse to linguistic forms (metonymies) created misunderstandings and reinforced misconceptions regarding which model should be used in each situation. The ambiguity of these models is not easy to eliminate: students bring their theories about the world, which are based on their own direct experience, everyday language, and scientific theories that have not been fully assimilated, as demonstrated during the interactions that took place in episode 2. In episode 4, this ambiguity remains unresolved because the labwork activity proposes two forms of semiotic representation (naming and coloring in the notebook) that induced the students to consider both situations (mixing lights and coloring on a page) as similar. This led some students to propose a white filter to obtain white light. Finally, the discourse analysis showed that common sense knowledge interferes with physics-specific knowledge, as shown by the frequent undue use of visual arts terms (blending of colors) in place of physics terminology (names of colors), revealing underlying concept misunderstandings (the role of filters) and factual misconceptions (additive and subtractive synthesis). The strategy chosen by the research-development project to elicit predictions based on prior knowledge, compare two types of results, and conclude with practical experimentation was fruitful, but did not succeed in clarifying the two competing cultural models of colored light for the students.

ACKNOWLEDGMENTS

This investigation was supported by CAPES (Brazil) and INRP (France). We wish to thank the students and teachers who were filmed for this study and Gerald P. Niccolai, who kindly agreed to revise the paper.

CAN NEW APPROACHES IN SCIENCE AND TECHNOLOGY EDUCATION ACT AS A MODEL FOR RATIONALIZING SOCIO-CULTURAL AND HUMAN VALUES IN OTHER SUBJECTS?

Mohammed Reza Behrangi

University of Tarbiat Moallem,Tehran-Iran

Behrangimr@yahoo.com

ABSTRACT

A new approach to teaching and learning has been conducted in teaching 54 chapters of four academic texts in four graduate courses within a four year longitudinal semi-experimental case study (216 cases) in educational administration emphasizing students' participation in teaching, promoting cognitive, personal, social, and behavioral skills and changes in their socio-cultural and human values. The approach maps the existing curriculum in each of 54 chapters, generating new map using tenets of curriculum planning in structuring critical concepts, plans for its feasibility in teaching titles and subtitles, plans for using teaching models and technology that fit the instruction, implements the lesson designed accordingly and, evaluates the instructional and nurturing effects on students' socio-cultural and human values of each chapter. A researcher developed questionnaire of 250 items was tested for reliability and validity and reduced to 72 indicators to measure instructional effects. Another developed questionnaire with 100 items designed to measure the changes and interpret students' attitude in socio-cultural and human values. The effect size tools measured the significant effects of the approach. The interrelated 7 models of information processing teaching and 10 chapters of "Supervision", and curriculum map- making are demonstrated here as examples for purpose of transparency.

Keywords*: Rationalizing values, instructional effects, nurturing effects, curriculum map.*

INTRODUCTION

Thinking inductively is inborn and lawful. This is revolutionary work, because schools have decided to teach in a lawless unnatural fashion, subverting inborn and innate capacity (Joyce, Weil & Calhoun 2009 p.83 quoting from Hilda Taba). This introductory statement outlines the message of this article, indicating a new approach is needed as an alternative to protect learners from the destruction of their innate and natural capabilities and aptitudes. The trend to rationalize existing educational administration gives power, restraint and inertia to education to remain at rest, although it sacrifices and endangers students' understanding and concepts attainment. This article provides direction for changing path of traditional education to a sustainable education that has instructional and nurturing effects to the utmost.

THE REVIEW OF LITERATURE AND EXPERIENCES

The emerging approach has a legacy of teaching and learning behind. This legacy has been studied and many years of the author's teaching experiences were used to clarify how to manage teaching to enable students to grasp real science and technology concepts. The main purpose of the approach was to bring ideal and desired instructional and nurturing effects of teaching and learning. Many well-developed models of teaching supported with many lines of researches on their effective size were used. Each of the models makes instructional and nurturing effects on students secured if used. From the 72 questionnaire indicators prepared for gathering data referring to instructional effects one could come up with the conclusion that how the diversity of teaching in different classes, in different cultures and countries has different effects on students and how far today education is from the collective and globalize world ideas on successful and satisfactory teaching. A professional and successful teaching should lead the students to be able to: understanding science concepts, constructing integrative knowledge, finding facts and framework for analyzing social problems and issues, creating scientific definition for phenomena, providing theories from inquiring facts, solving problems through inquiry, making hypotheses on facts, making meaningful assimilation of information and ideas, construct mining of scientific concepts, to be empowered to use tools for metaphoric thinking of science objects, being in the seine to catch new discoveries, gaining the sense of intellectual power, equipped with the intellectual tools for mastering information and concepts, endeavor to reach at the level of mastering of facts and ideas, enhancing strategies for creative inquiry, getting involved in scientific process, using concept learning strategies, understanding the nature of science concepts, making use of concept-learning strategies, applying conceptual systems, forming hypotheses, being involved with concept formation processes. These are some of the indicators of a professional instruction effects on students learning.

On the other hand the nurturing effects (beside the instructional effects) of a professional teaching on students could be seen through administering another questionnaire with 100 indicators as a guide line for students to be empowered with: reflective thinking, self-understanding, integrative communication, ability to assume role of the "others", effective cooperative spirit and skill in group process, empathy, pluralism, awareness of the nature of knowledge, spirit of inquiry, tolerance of ambiguity, conceptual flexibility, comprehensive, penetration, collaborative skills, open-mindedness, ability to balance alternatives, spirit of creativity, autonomy in learning, understanding tentative nature of knowledge, self-esteem, self-understanding, self-reliance independence, and habits of precise thinking.

These two researcher developed questionnaires were provided through cross-cultural comparative and in-depth studying, analyzing the literature and history on researches done on teaching and learning, analyzing too many scenarios of teaching in different levels and grades in different cultures and countries to demonstrate instructing and nurturing indicators of ideal teaching. Each of these instructional and nurturing effects indicators has been based on much research to prove their usefulness.

For the cause of transpiercing of the findings of the literature the studies were referred to in a four components used by Bruce, et al (2009). They classified the models of teaching into social, information processing, personal and behavioral family of models. For the purpose of this study and to demonstrate the instructional and nurturing effects of teaching on socio-cultural and human values of students at all levels of schooling, the 7 models of teaching in the family of information processing models of teaching were dissected and categorized into one group based on the instructional effects on students' learning. These 7 models are:

1- Learning to think inductively- forming concepts by collecting and organizing information,
2- Attaining concepts- sharpening basic thinking skills;
3- The picture-word inductive model- developing literacy across the curriculum;
4- Scientific inquiry and inquiry training- the art of making inferences;
5-Memorization – getting the facts straight;
6-Synectics- the arts of enhancing creative thought;
7-Learning from presentations- advance organizers. Therefore, using these models of teaching is to lead teaching to have instructional effects on students' performance and race to catch the 75 indicators of a professional teaching.

The rest of the models of teaching were dissected and classified into the second group keeping direct emphasis on socio-cultural and human values in mind. The second group of models of teaching was formed with regard to their nurturing effects on students' values and growth. The presumption on the one hand is that if teaching takes place using the models with instructing effects in mind then the result would be its effects on nurturing students socio-cultural and values. On the other hand, the presumption for an effective instruction is also that the nurturing models of teaching enhance the instructional effects of the first group of models of teaching. These two presumptions are interrelated. With the use of the nurturing models of teaching as a base and bed for getting use of instructing models of teaching the class environment is enriched to improve students learning in all dimensions of development.

In using the group investigation model of teaching or role playing in the class situation, as an example, students are empowered to work better together and be motivated to make discoveries and use their creativity. Therefore, it affects indirectly the instructional effects on students' learning improvement. The data were gathered through the studies on these nurturing models of teaching for the reason to justify, support and supplement the instructional effects of the models.

The second group of models of teaching with nurturing effects includes:
1- Partners in learning- from dyads to group investigation;
2- The study of values- role playing and public policy education;
3- Jurisprudential inquiry- learning to think about social policy
4- Nondirective teaching- the learner at the center;
5- Developing positive self-concepts- the inner person of boys and girls, men and women;
6- Learning to learn from mastery learning;
7- Direct instruction (Joyce et.al.2009). Through using the nurturing model of teaching the affective skills of students will promote and enhance their understanding of instructional concepts much better.

Steps used in a new master approach in teaching

This new approach has five steps as shown in Table 1. Step one is designing a map for titles and subtitles of each chapter of the existing texts considering the critical concepts in mind.

Table1. Step by step approach in teaching with instructional and nurturing effects in mind

1-Map of the concepts in the existing curriculum	2-Modified Map of the critical concepts, indicating which concepts best accepts which model of teaching and technology?	3-Preparing learning environment indicating Which study methods fits learning modified curriculum?	4-Leading student's active involvement in a curriculum that is harmonized with instructional and nurturing effects on students	5-Measuring information processing skills, knowledge and socio-cultural and human values

Table 2 shows the scattered titles and subtitles of the first chapter of "Supervision" course in the department of educational administration, as an example. The critical factor in this example is the fact that curriculum planning and the models of teaching are combined and integrated in these steps. There is an underpinning fact of this research which demands professional skills of teachers to become able to make use of curriculum planning to match their lessons contingent upon students' needs and class situations. It shows who is professional and competent to maintain the profession on the route of fulfilling educational goals. In the traditional and existing situation it is rare to see the teacher play the role of curriculum planner adopt teaching model and match it with the academic subjects and suitable technology for the improvement of students' learning. The teacher shows professional competencies as commitment to the educational goals of bringing up a well developed whole body of individual students. Through using the steps in sequent (i.e. mapping the concepts in the existing curriculum, preparing modified and desired map of the critical concepts, indicating which concepts best attracts which model of teaching and technology, preparing learning environment indicating which study methods fits learning modified curriculum, teachers lead student's active involvement in a curriculum that is harmonized with instructional and nurturing effects on students, and at last measuring information processing skills, knowledge and socio-cultural and human values. The consequent steps are: designing an ideal map considering the curriculum planning tenets such as hierarchical and horizontal liaison, and integrity of critical concepts, considering feasibility for teaching in the new map, selecting models of teaching and suitable technology of education involving students and managing class environment for learning, implementing the approach and evaluating its instructional and nurturing effects on students. The students are asked to participate in curriculum plan, selecting models of teaching and suitable technology for learning critical concepts of chapters, titles and subtitles of the texts.

Sample courses using the approach

So far the master model of learning that overhaul learning activities of any class has been explained in theory. The model has been used in practicing teaching four academic texts with 54 chapters in the graduate school of education namely, Theories of Organization_and Management (Scott Rechard, 2003), Models of Teaching (Joyce, Bruce and et.al, 2009), Strategic Management Information Systems, and Techniques, (Rowley 1994), and Supervision, A Guide to Practice (Wiles, Jon & Bondi, Joseph 2004) have been experienced. The practice has been started from two years ego and it is deemed to be continued for two more years.

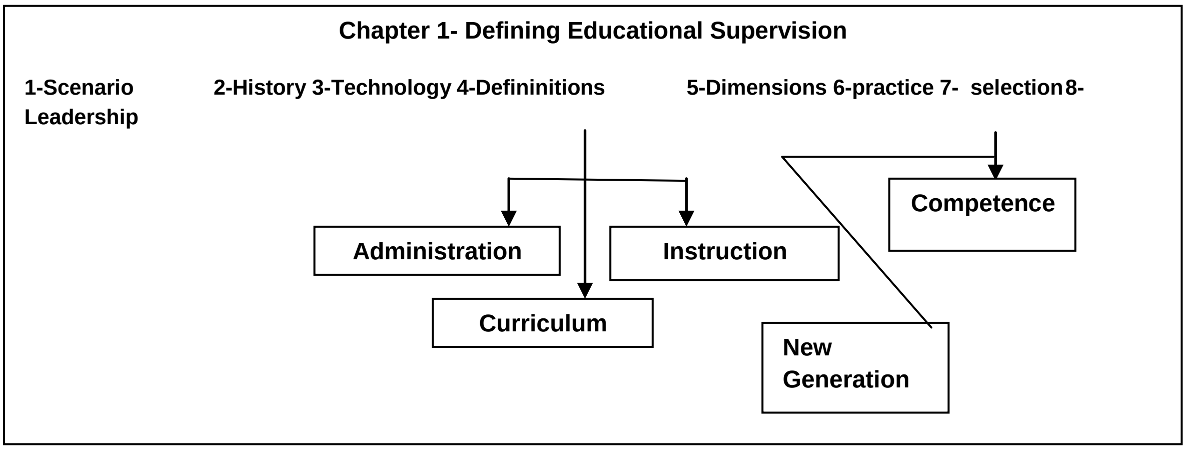

Table 2- scattered titles and subtitles of chapter one of the book "Supervision" in Bondy et.al 2004

Table 2 shows very scattered 8 major titles in a very general term. It is difficult for students to maintain them in mind because of their dispersion. It is not very easy to remember them, connect them in mind, construct knowledge, and get a clear map of meaning in mind from them. In Table 3 a new mind map shown with five general terms is considered very meaningful and likely to be taught and learned.

Table 3- six dimensions for chapter one defining Educational Supervision

As an Act of administration	**As an act of curriculum work**	**As an of Instructional function**	**As an act of human relations**	**As management**	**As a generic leadership role**

Table 3 shows a summary of the chapter content in a new mind map constructed to give the main idea of the chapter. It works as an advance organizer and links the main title of the chapter, and five titles derivative of the whole chapter. In this way the instructors are able to make the changes in curriculum and provide a new map having the class environment, model of teaching, suitable educational technology and existing understanding of their students together in mind. The aforementioned curriculum development is used now for managing the use of models in teaching. In Table 4 one could consider the cross interrelated models of teaching and the main title of each chapter.

Table 4- Mind map for matching 7 models for instructional effects (from Joyce et.al 2009) with 10 chapters of Supervision (from Bondy et.al 2004)

Models → Chapters ↓	inductive	Concept attainment	Picture-word	inquiry	Memorization	cynectics	Advance organizer
Defining supervision				MEAN= 55.13 S.D=6.621			
foundations						MEAN= 62.7 S.D=7.843	
Professional knowledge					MEAN=64.38 S.D=7.354		
Designing curriculum	MEAN= 64.38 S.D=7.354						
evaluation			MEAN= 64.38 S.D=7.354				
Human relation		MEAN=55.1 S.D=6.621					
Staff development			MEAN=64. 38 S.D=7.354				
Administrative function	MEAN= 51.6 S.D=5.841						
New direction				MEAN=55.1 S.D=6.621			
	MEAN= 51.6 S.D=5.841						

Table 4 shows the act of teaching and using a model of teaching in each chapter. As was mentioned before, the findings have not been completed. It is only an example of how to make the work going a head. The 72 indicators are being used and statistics of mean and standard deviation have been calculated for a few experiments arbitrarily as have been shown in each box of the Table 4. The Table is only an exemplary sample of the trend in using master model of teaching. There are blank boxes in the Table because the study is underway and still needs the results of many case researches to come up. One should take into consideration that Table 4 is an example of how to use models of teaching in a course of study regarding its content during one academic term. It is under construction in regular successions. The effect size of the teaching through the approach is significant. This trend of mind mapping can have several advantages as follows:

1- It can be used as data-base or storage of expert knowledge with new information implying expert system application in curriculum development.
2- It can be improved in each academic term through action research and feedback on the instructional and nurturing effects on learners.
3- It can be used by the next generation of students that take the course for seeing the process of producing knowledge
4- It is flexible for grasping and adding new material to bring the content up to date

5- Students see a clear route for searching different sites and add to the already existing material.
6- The result of any need assessment for related content and improving the quality of the courses in the department of educational administration toward fulfilling of the goals can be taken into consideration.
7- The process and the cycle of clinical supervision (planning conference, class observation, and feedback conference) could be planned for teachers to improve the instructional and nurturing effects on students.

The result of any need assessment to related content in improving the quality of the courses in the department of educational administration toward fulfilling the goals can be taken into consideration. To prevent the article from being too long of the normal size, as Table 4 shows "Supervision" as one of these books with 10 chapters is considered arbitrarily. Table 4 explains how the teaching will be provided in more details with regard to the titles of each lesson. The master model approach reiterates the use of participation model of teaching and advance organizer model of teaching in the entire teaching plan of all the chapters of the book. Inductive model of teaching has also been approved for its general uses and effects in teaching. It is possible to combine together picture-word inductive model of teaching and inductive scientific model of teaching to enhance more effect size. Table 4 has not been completed. It identifies research still to be completed. The process of case study research is continuing to complete the Table since the research style is longitudinal and takes two more years to be completed. The Table works as data base form (kind of data used in expert system) for storage of expert ideas on the instructional effects of models of teaching across the chapters of the Supervision book. There are 110 graduate students in educational administration department who are potentially involved in action research to conduct teaching according to the approach and scenarios that are prepared in the four courses. The statistics noted here have been provided from 15 students participated in the course of supervision. They are used temporarily for the purpose feasibility and should be improved with gathering more data on implementing the approach in more academic coming terms in all the four courses in educational administration. There is also the possibility to use pre and post testing on their understanding and compare their success with the traditional way of teaching. For these points of views, therefore, it is necessary to work on producing different suitable tools for measuring instructional and nurturing effects on students learning and development. Although, the 72 indicators are used to show the instructional effects of the approach and although the 100 indicators for nurturing effects are used as a tool for measurement of the effects, there is a need for pencil and paper teacher-made test too for comparing academic achievement. There is also a need to improve standard items to show the indirect effects or nurturing effects of the teaching approach.

In Table 4 one can see the statistics related to implementing models of teaching in teaching chapters of the "Supervision" in an academic term with the class size of 15 students. The calculation was done using SPSS version 15. Using eclectic models of teaching was intended but with emphasis on each model in each session. 'Advance organizer' and 'Partners in learning' were the common models of teaching used in all of the lesson plans and their implementation.

METHODOLOGY AND RESEARCH PLAN FOR FOUR YEAR'S LONGITUDINAL SEMI-EXPERIMENTAL TEACHING IN FOUR GRADUATE COURSES

The cohorts of graduate students attending the school of education in the past two years were considered to be taught according to the approach. At the beginning it was done arbitrarily and with hesitation to be successful in managing the class for the changes to occur. The trend in this approach clarifies that each student takes the leadership role in conducting the teaching for the designated chapter according to the selected scenario of teaching. In each scenario there were specified models of teaching and critical concepts of the chapter (see Table 4 as an example). Suitable educational technology is used and accommodation for its use is prepared.

There are a lot of flash carts each prepared for critical concepts in each chapter. They are prepared by students with the help of the instructor and are used mostly for students' engagement, pear group and partners in learning and participation in the process of gathering data, classifying the data into information, coming up with the specific and critical concepts in each title, analyzing together the concept in search of finding and classifying features of any cases belonging to the concept, creating definition for the concept and being prepared to anticipate the belongingness of unknown cases to the concept definition. This trend and process of learning through gathering data and making information and defining the concepts for further application was an intellectual skill of learning that students were expected to master in learning different subjects.

The instructional effects are assessed through a researcher - made questionnaire of 250 items which was reduced to 72 items through statistical reliability and validity tests. The Professors Committee of Experts and Cronbach Alpha were used for this purpose. The Effect Size formula {ES= (average of experimental group--average of control group)/ standard deviation of control group} is used to see the significant differences of the new approach of teaching in comparison with the traditional and existing teaching approach. The nurturing effects are assessed through the second researcher - made questionnaire using 100 items referring to the socio-cultural and humane effects in three categories (i.e. personal, social and behavioral) on students' attitudes.

The findings are discussed with all the cohorts of graduate students' researchers who participated in the research. Each one prepared their research findings on the effect of conducting the teaching approach in their related subjects. The 72 indicators of instructional effects that measure the students' attitude toward the acceptance and desirability of the approach are implemented. As shown in the Table 4, the search has not been completed since it is a longitudinal approach and needs more feedback and evidence to be summed up in the final conclusion.

The approach continues to be implemented with the next cohort of graduate students and for stronger ratification. As a matter of fact, the approach acts as an expert system to accumulate the results of each conduct in its storage data base and use feedback for improvement through new implementation. Although the research see the instructional and nurturing effects of the approach regarding changes in socio-cultural and human values on personal, social, behavioral, and information processing skills and the results are already successful, able to be generalized therefore the approach is suitable for teaching other courses in the sustainable trend of improvement.

Furthering this research there is a need for questionnaire items to be categorized and analyzed using factor analysis to prepare a reduced questionnaire through using the critical factors for suggesting suitable, flexible, and comprehensive model for teaching and learning of all subjects in different branches of knowledge in science and technology education. The approach then will be considered in curriculum planning and teaching scenarios in each of 54 chapters of the four academic books in the graduate department of educational administration.

The instructional and nurturing effects of the teaching according to Scenarios will be analyzed through using SPSS software. The significant finding is that the use of the approach could be generalized not only for the graduate school of education but for teaching and learning science and technology education as the whole.

CONCLUSION

Although the aforementioned explanations and steps taken to carry out the approach have shown the feasibility of making arrangement for the changes, there is still the need for supportive actions and supervision to generalize the approach for use at different courses and levels of education. In this student - oriented rather than teacher - oriented approach students are not only learning the critical concepts of the lessons better but their skills to cope rationally with socio-cultural and human values will be increased. The presumption that instructional effects of this approach enhance the nurturing effects and vice- versa is a good indicator that focuses on one of the most negligent factor in the history of education.

The approach will help put juvenile intelligence on old shoulders rather than putting old head on young shoulders. The instructional effects are stored in 72 indicators and the nurturing effects in 100 items questionnaire which have been provided in an in-depth study of the literature. These items have been discovered through cross cultural studies and the analysis of different scenarios of teaching and could be used as a standard of a successful teaching. They have been shown reliable and valid through calculated statistical approach and are known secured to be used. Some of the items that measure the instructional effects on students are: understanding the process of attaining concepts, obtaining the skill of classifying data to make information, creating definition for unknown phenomenon, overview of the process of producing concepts, making connection of new concepts with the mental construction of knowledge, enhancing self education, using meta-cognition in learning, improving self scientific observation, increasing the memorization potential, being able to weigh alternative for solving problems, using critical thinking approach, learning the way that scientist use for developing the concepts, learning inquiry approach in solving problems, internalizing learning, linking known concepts with unknown materials, reconstructing the new images of concepts, and so on.

The items on nurturing effects are more important than instructional effects mostly because they are sustained in one's whole life. Their final effects should be calculated by multiplying their effects by the time they are used in whole life. Some of the nurturing items that affects students' behavior are also: having mutual understanding in learning, finding self in the field, improving inquiry inclination, improving critical thinking, maintaining patient and tolerance in critical situation, using comprehensive, flexible and penetration in discussions, being self directed person, having individual self–awareness, evaluating new concepts, understanding feeling of themselves and feelings of others, using sympathy and empathy in relation to others, understanding their uniqueness, feeling internal rewards for understanding, self evaluation, learning independently, having a positive attitude toward themselves, acting on the base of rationalized accepted values, being aware of social and individual values, having respect for others, improving human relation, having a life philosophy, finding the meaning of self in life, being patient in evaluation of others' idea, working in a group of peers, being motivated to learn and doing according to their logical understanding and so on.

Using the approach makes a significant change in the trend of already existing teaching, improves the quality of teaching and the curriculum, and lets students to be improved in learning with a good motivation to learn. It is basically oriented to students' learning improvement and works with students' involvement in all the process of attaining concepts and learning. The results of the approach have been so far so good to be implemented in teaching not only the aforementioned four courses but in all grades and levels of education. There are a heavy burden of its implementation in teaching other subjects and it need supportive action from educational administration and educational systems for making general policy to carry it out.

ABSTRACT

The combination of real and virtual environments in general science education is a current challenge for school curriculum in the period of information society. The paper describes theoretical background, starting points and design of a research project in this area. Possibilities of real and virtual school chemical experiment and their combinations will be analyzed. They bring a new dimension not only to laboratories, but also to everyday life of students, teachers and everybody interested in science education. New possibilities to measure, to control anything from any computer, to receive current data from the opposite part of the world – these are incentives of strong motivation. The project design, including pilot results, is presented on the example of laboratory work "pH measuring". Two as much as identical scenarios were prepared using either real or virtual pH-meter, managed by worksheets containing tasks of three levels: pH measuring of different solutions, answers to problem-based questions and open-task to create a set of next pH measuring. The first received results are presented and discussed in this article.

Keywords: *Early chemistry education, experimental activities, general science education, combination of real and virtual chemical experiment, simulations, pH-measuring*.

INTRODUCTION

Currently the real life brings more and more virtual environment items, new virtual worlds etc. Both children and adults are strongly motivated by experimenting, discovering and understanding things in their own way. The school experiment is to be purposeful, i.e. clear, appropriate to pupils´ age, simple, well organized, visible and safe. Is the remote or virtual (simulated) experiment able to meet these requirements? The objective of our research project is to determine possibilities and their limits in the use of virtual environment supporting early science education, paying special attention to the early chemistry instruction. It means to research effectiveness of computer simulations and natural science (chemical) animations applied in early chemistry education (basic school, grades 8 – 9, 13 – 14 year-old pupils), either independently, or in various combinations with the real experiment. The core of the research is to discover the relations and provide recommendations for meaningful and effective use of computer simulations and animations, remote and virtual laboratories, etc. (Bílek et al., 2009).

THEORETICAL BACKGROUND

The orientation of natural science instruction (including chemistry) towards methodological tools in natural science cognition, i.e. empirical methods (e.g. observation, measurements, school chemical experiment), and theoretical methods (e.g. modelling), originates not only from its basis and subject of chemistry as a scientific discipline, but mainly from the characteristics of the methodology. When researching chemical features of substances or phenomena, it is necessary to join both empirical and theoretical processes in running a real experiment as the most powerful methodological means in natural science cognition. Its position is unsubstitutable even in the chemistry instruction, where it appears in various forms, e.g. it works as s demonstrational and pupils´ experiment, and provides:

- motivation,
- starting information about the studied object,
- information on veracity of the learning content.

The following tasks are to be solved, so as experimental activities can be improved and a wide range of functions in the process of cognition emphasized:

- defining single phases of observation focused on finding basic features of the observed objects or system,
- working out the process of cognition, including the thought experiment in chemistry, which is understood to be a certain form of modelling,
- analyzing an experiment as a method of cognition, mainly from the point of its function in the process of cognition,
- aiming at practical activities when running the experiment in the problem-solving instruction.

Certain results have been received from the works which deal with the position and functions of current chemistry methodology elements and other natural sciences in their didactic systems. Following aspects and approaches may appear, e.g.:

- relation between the problem-solving principle and the system of experimental activities in chemistry instruction,
- mathematics and logic in the methodologically run chemistry instruction (mathematics as a methodological tool in the process of natural reality cognition),
- modelling and models in teaching chemistry and other natural science subjects,
- the issue of the development of material didactic means for methodologically oriented chemistry instruction.

This area also includes innovations of material didactic means. Attention is paid mainly to those supporting school experiments with data administered by computer, computer simulations in the form of web applets, remote and virtual laboratories.

The subject of chemistry is again affected, as it was in late 1980s, by discussions on new content, questions on the effectiveness of organizational forms, methods and procedures, adequacy of applied didactic means. It keeps on emphasizing general rules defined by Hellberg (1983) which call for:

- increasing the demands on abstract thinking in the process of instruction,
- removing unimportant items and emphasizing general character of single subjects,
- learning to understand the given subjects in relation to similar ones.

This requires increasing effectiveness and frequency in using the essential methodological tool of natural sciences, i.e. the school chemical experiment, and at the same time applying new didactic means, mainly those on the digital basis.

Methodological aspects cannot be omitted even in applications of information technologies in the science (chemistry) instruction. Starting from this point of view, the basic and general methodological tools (methods) are as follows:

- empirical methods: simple and controlled observation, real experiment, work with empirical hypothesis,
- theoretical methods: thought experiment, modelling on different theoretical levels (material, mental, mathematical), work with theoretical hypothesis.

Simultaneously it is possible to advocate that two sciences function each other as methodologies, mainly in situations when the science reflecting simpler fields of phenomena carries out the function of a methodological tool towards the other science which solves more complicated problems. Thus Physics is the methodological tool towards Chemistry, and Chemistry towards Biology. Sometimes another situation may appear - a more abstract science, e.g. Mathematics, is the methodological tool towards the other sciences (Hellberg and Bílek 2000).

The function of the interactive medium is not directly, but vicariously methodological. It enables to apply basic empirical and theoretical methods in a faster, more complex way, and to save their results into memory in long-term periods, and to provide information on the history of the studied phenomenon at any time. This is a substantial auxiliary tool allowing improving methodology of gaining new and applying still existing pieces of information.

When considering the above presented aspects, computers have an important role in connection to any other basic empirical or theoretical methods, or in mutual relation between them. Above all, they can work as a database of information gained in continuous monitoring, or control processes on all quantitative levels – laboratory (micro-, semi-micro-, macro-) instrumentation and operating. This is the main way of ICT implementation in natural science practice. They serve as a tool enabling (Hellberg and Bílek 2000):

- numeric operations (similar to high-level calculator);
- monitoring, continuous assessing and saving data to memory after "live" observations (controlled observations) and real experimenting;
- modelling of these procedures – and working as their simulator; it assumes there exists a mathematical model of the appropriate methodological procedure; the model is the starting point in creating the appropriate simulating programme;
- a wide range of other possibilities in modelling activities which the computer is used in, especially creating the model, in case of simulations applying the model, and interpreting it;
- complicated examples, when a large extent of information on the given class of things, objects, substances, phenomena is inserted and computers work as advisors (experts) in the given field – expert and knowledge systems.

The particularity of natural sciences, and especially chemistry, lies in the sphere of observation of the course of chemical experiments (sensoric area) and in forming conditions for their repeating and changing (motoric area). It is obvious that intellectual activities are a necessary part of every sensomotoric (or either sensoric, or motoric) activity. This topic has been dealt by numerous authors, e.g. H. Riedel (e.g. 1990, 1991, 1992, 1994) worked out the theory of internal operations. He distinguishes:

I. Cognitive operations - operations when information enters the mind:

- cognition - from the surrounding world,
- recalling - from memory.

II. Production operations - operations of processing information:

- forming - operations of further transferring and structuring:
- remembering - transferring to memory,
- evaluating - observations in mind,
- transforming - forming operations and connecting them into new information,
- model-oriented - a model, continuity, planning,
- convergent thinking – depending on a certain thinking pattern,
- divergent thinking - not depending on the original pattern in favour of other ones,
- spontaneous thinking - without any pattern, by leap:
- original way of thinking.

The above presented types of activities are applied in both procedures (theoretical and empirical) of learning any topic. The dominant (or initial) activities in the theoretical procedure are the intellectual ones, in the empiric procedure – sensomotoric activities. The simplified analogy of both procedures in displayed in the schema according to Čtrnáctová (1982) (see Fig. 1).

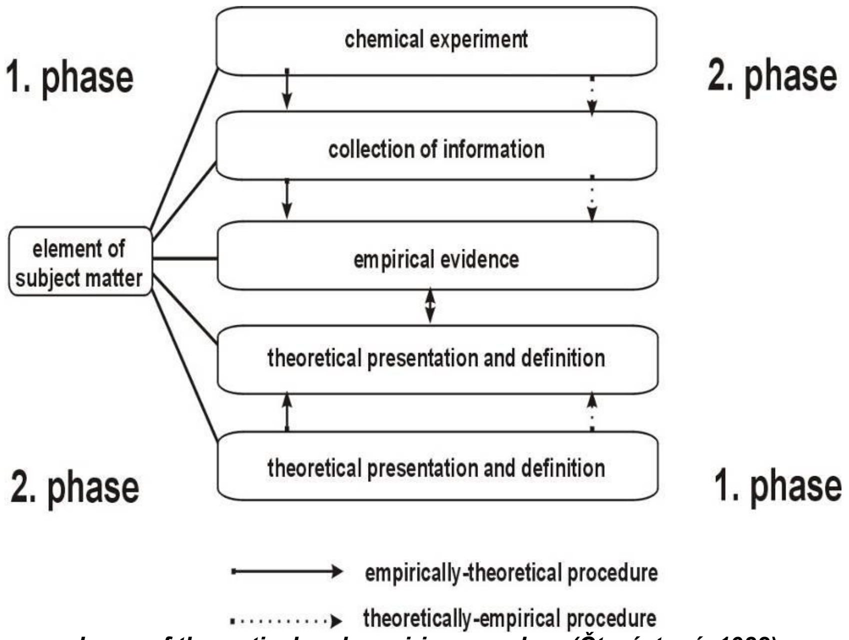

Figure 1 Two-phase schema of theoretical and empiric procedure (Čtrnáctová, 1982)

The schema proves that the procedure and evaluation of the chemical experiment are analogical. That is why pupils´ activities, when running and evaluating the experiment, and in theoretical explanation of the given pieces of knowledge, are similar. The difference is shown in teacher´s activities, i.e. in the way of directing the appropriate phase of the educational process (Čtrnáctová, 1982). The above mentioned pieces of knowledge are concretized in a model by Hellberg (1983) which does not reflect basic methodological tools of cognition, but natural reality in the process of natural science education. The following schema (Fig. 2) displays structuring into two fields. The sensory-concrete field of thinking is on the left, the concrete thinking is on the right. The fields may be also called "inductive-concrete thinking" and "deductive-concrete thinking".

As it has been indicated above, computers and other information technologies can be used as useful supporting means of emphasizing methodological aspects of natural science instruction. According to Fig. 2, they are mainly as follows:

- support to running experiments and modelling (computer - A),
- support to directing empiric and theoretic hypothesis defining (computer - B),
- support to forming empiric and theoretic items of knowledge (computer - C).

Information and communication technologies play the role of traditional didactic means which aim at optimizing educational conditions, i.e. support planning, projecting, running and evaluating instruction so that the educational objectives were reached, and reached in an effective way. Opponents emphasize the factor of the learner, which is missing or considered a passive object of learning. In our latest monograph (Bílek et al., 2009) we are trying to outline the meaningful combination of the real and virtual environment in the natural science (chemistry) instruction which is one of the crucial conditions in the process of innovation of school experimental activities.

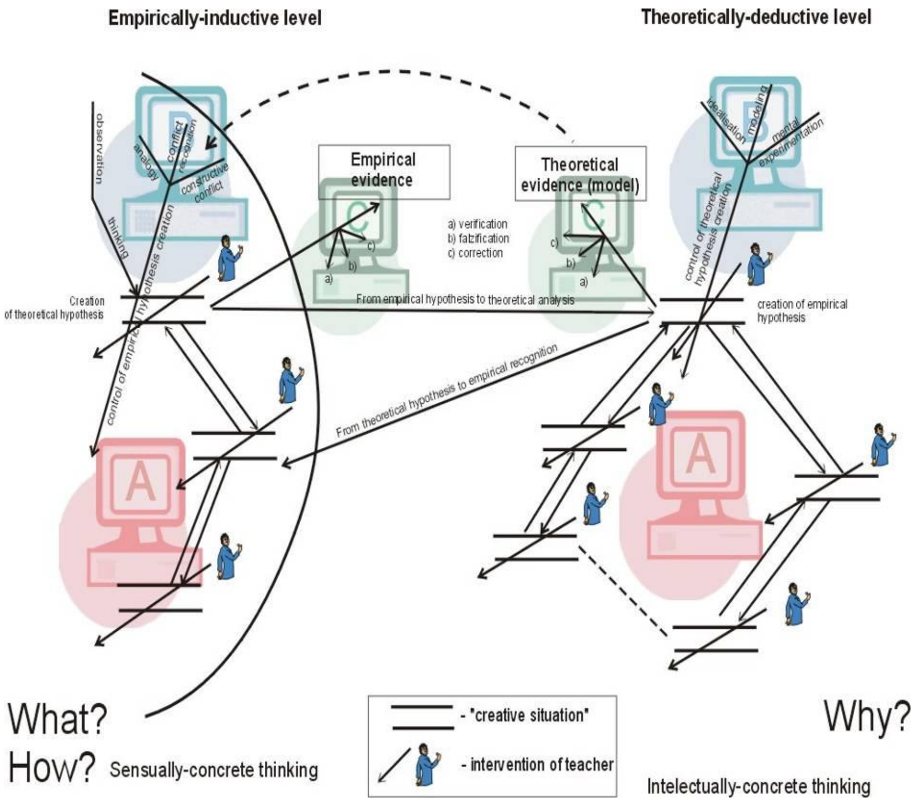

Figure 2 Model of basic methodological tools of learning natural reality in natural science education accompanied by various types of computer support (Hellberg, 1983, Hellberg and Bílek, 2000)

PILOT RESEARCHES AND FIRST RESULTS

In the first part of the research project various proposals combining a real and virtual experiment were designed and considered by chemistry students and teachers who participated in the courses "Computer supported school chemical experiment" and "Chemical educational software" at the Chemistry Department, Faculty of Education University of Hradec Kralove (Czech Republic). Totally 78 students of the 4th and 5th years (study programme Teaching Chemistry) evaluated four combinations below:

- simulation after real experiment for explaining its principle,
- simulation after real experiment for fixing knowledge,
- simulation before real experiment for explaining its principle,
- simulation before real experiment for training the activity.

Acid-base titrations, experiments with galvanic cells, measurements with spectrophotometer and pH-meter were used as examples. Most students preferred running the real experiment to the virtual one, and mainly using the simulation of experiment for explaining its principle. It was interesting that students did not consider the "training" role of simulations to be important for practising work with laboratory apparatus, understanding principles of laboratory procedures etc. (Bílek and Skalická, 2009).

In the second part of the research project the main topic refers to experimental activities of pupils in general chemistry education. The basic school pupils undergo a pilot research on laboratory pH measuring supported by real and virtual (simulated) apparatus, i.e. a virtual pH-meter, which is an available simulation on T. Greenbowe Web page (Greenbowe, 2009), and a hand-operated pH-meter in real set on the laboratory desk.

After lessons "Acidity and alkalinity of solutions" two as much as identical scenarios were prepared using either real or virtual pH-meter, managed by worksheets containing tasks of three levels:

Level 1: simple pH measuring in three samples of selected chemical substances (hydrochloric acid, sodium hydroxide and sodium chloride) in three different strengths.

Level 2: answers to problematic questions followed by verifying them by measuring changes in parameters of the substances (concentration, volume, similar chemical substances), e.g. What pH value will a certain volume of hydrochloric acid solution reach having lower/higher strength than in the previous measuring?, How will pH sodium hydroxide with strength of 0.06 mol/dm^3 change when its volume increases from 100 ml to 150 ml?, What pH value will potassium hydroxide solution reach in comparison to sodium hydroxide solution if the strength is the same?

Level 3: open task, e.g. Design and describe assignments and results of other tasks which you could do with the provided aids and real or virtual chemicals. You can ask your teacher to provide you with other chemicals and aids for the real experiment, or give you advice on other functions of the simulated pH-meter for the virtual experiment.

The following hypotheses were set for this research: (1) No statistically significant differences will appear in pupils´ results of pH-measuring in provided solutions of chemical substances with the real and simulated pH-meter. (2) No statistically significant differences will appear in pupils´ answers to problematic questions dealing with pH-measuring in solutions of concrete chemical substances by the real and virtual pH-meter. (3) Pupils´ recommendations on using the laboratory arrangement for other measurements will be more frequent and varied, i.e. more proposals will appear, and the teacher will be asked more questions relating to the real environment than to the virtual one.

The pilot research ran at two basic schools during compulsory laboratory lessons in Chemistry. Totally 85 pupils (four groups) of 8th grade (13 – 14 year-old) participated. The applied method was the pedagogical experiment of crossed groups, i.e. two groups started work with a real experiment first (see Fig. 3); two other groups started with a virtual measuring (see Fig. 4). In the next lesson (3 days later) the groups changed the environment.

Figure 3 Pupils working with real pH-meter

Figure 4 Pupils working with virtual pH-meter

Pupils worked in the same groups of two or three during both parts of experiments (virtual and real). Having finished the lessons their worksheets were analyzed on all three levels of tasks. During the lessons pupils´ reactions were recorded, e.g. types of questions, which should help to modify the worksheets and provide methodological recommendations for the follow-up research with a wider group of respondents, which is planned for the 2010 year.

The analysis of pupils´ results on Level 1 unreservedly verified the hypothesis. In pH values collected from real and virtual pH-meters no statistically significant differences appeared. On Level 2, which focused on problem-solving tasks based on previous activities and pupils´ common experience, statistically significant differences were identified between groups working in either real or virtual environment in the first round of measurements. Consequently pupils applied the experience they had received in the first round. Their results were better and statistically significant differences were not proved. Results of Level 3 were tensely expected, as they were to provide proposals for follow-up measurements, procedures, explaining consequences etc. Based on experience we expected the real environment to provoke wider variability of proposals than the primarily varied, but limited virtual environment. The reverse was true. More proposals were recorded just in the virtual environment. Although it was obvious from direct observations, pupils asked more frequently about other possibilities of working with the real pH-meter, they did not write down the questions to the worksheets. Generally it must be said fewer than half of respondents (43 %) filled in this part of the questionnaire only.

The pilot research of the influence of the real and virtual environment on pupils´ experimental activities proved our assumptions to a considerable extent. So that the research could be applied on a more numerous sample group, several small changes of worksheets were identified, and an essential one – the hypothesis relating to Level 3 must be redefined towards using stronger motivation of the virtual environment.

CONCLUSION

The feasible real experiment should not be in any way eliminated from school laboratory practice. Forming and improving manual skills (measuring by available laboratory instruments, working with laboratory systems, even constructed from common subjects of everyday use, working with safe substances), which are substantial part of natural science education, cannot be fully replaced by practising through monitor and keyboard. On the other hand it is impossible to avoid indirect observations and working with models and instruments. Researching these fields leads, or not, to proving intuitive estimations, which is important, as well as answering other questions resulting from this area of potential assets and threats.

BIOLOGICAL EVOLUTION TEACHING RESEARCH IN A SOCIOCULTURAL PERSPECTIVE

Nelio Bizzo

University of São Paulo

Bizzo@USP.BR

ABSTRACT

History of Science can provide not only good ideas for classroom practice, but also can throw light on educational research. The main problems scientists faced in the past can be similar to those students find today. We present results of a historical reappraisal of the process of elaboration of evolutionary theories, showing that the conception of deep geological time, contrary to what is generally admitted, had deep roots in the ground Charles Darwin was planting with his first thoughts on natural selection. Marine fossil remains in mountains had an original interpretation in Italian geology the century before, which had been fully incorporated by the geology of Charles Lyell. He was sure about the antiquity of our planet, and Darwin decidedly relied on him. The certainty of the antiquity of earth that emerged in the 18th century relied to some extent on the findings of a place where fossils are very well preserved and plenty of clear evidence of past environmentsexists (*Konservat-Lagerstätten,* literally "place of storage). This place is a small village, which invites visitors to revise their conceptions about the history of earth. We conducted interviews in this place with young students, in order to understand their views on geological time. Results show that interpretation of evidence follows different ways, as young students give several meanings to the extraordinary fossil remains they find every day. In addition, elements from History of Science suggest the need for a revision of the historical framework in which evolutionary theories are commonly seen in school settings and urge educators to pay more attention to scholar scientific definitions offered to students, which can give rise to unnoticed complex intellectual ecologies in the school context.

Keywords: Evolution Teaching, History of Geology, Geological Time, Science Curriculum Design

METHODS

Schools and educators try to provide understanding of scientific theories to young students, and there is a growing awareness that there is no direct transmission of knowledge from books or teachers' discourse to students' minds. Current instructional approaches for science teaching view learners as active agents in the processes of constructing meaning, which implies taking into consideration what the learner knows and believes on the subject. This set of ideas is frequently named "everyday knowledge" (or lay understanding) and is used by people to explain phenomena in their daily lives. In educational and cognitive psychology literature, such ideas have been described as "misconceptions", "prior knowledge" or "alternative frameworks". The knowledge that people hold is a potent force in determining which sort of evidence is judged as relevant and how information will be perceived. In social psychology, such ideas have been described as "social representations". One of our major aims is to understand processes which give rise to these social representations.

Explanatory statements of science are conceived as having a developmental history, which, together with its epistemological constraints, plays important roles in educators' decisions about curriculum design and teaching plans. Our group carries out research at these two levels, looking for contributions of the developmental history of science core concepts and teaching practices, considering wider social processes of meaning-making which influence students. This multifocal research program relies on what has been called "bricolage approach" (Berry, 2006), as a variety of tools and possibilities are brought together in order to help new understandings of apparently obvious social relations to emerge. Education is admittedly an area where complexity emerges, questioning some assumptions of causal relations, for instance, between teachers actions and student responses. This perspective does not allow isolating an object of the study from the complexity and multiplicity in which it is situated. Moreover, it decidedly does not aim at "solving problems" through the gathering of data which would drive drawing of answers and conclusions.

One of the major steps in these research programs is *problematizing*, in the sense that obvious understandings, apparently undisputable, can be seen from a completely different perspective, focusing upon both epistemic and psychological levels. In other words, clear statements about the historical development of scientific theories ought to be seen as aporetic and near-to-equilibrium teaching-learning conditions should be seen as unstable, trying to avoid a monological, single path or research method. This perspective requires an open-minded understanding – and knowledge – of

> multiple *theories* and *methodologies*, multiple ways to collect, describe, construct, analyze, and *interpret* the object of the research study; and finally multiple ways to narrate (tell the story about) the relationships, struggles, conflicts and complex world of the study that maintains the integrity and reality of objects. (Berry, 2006:90).

We have been trying to avoid the conception of narratives about the historical development of scientific theories of evolution as a crystal clear and objective description of a straightforward process. The historical research follows this path, trying to problematize what is seen as a monological development. There are rich contributions from the field of Critical Cultural Studies, as we recognize complex relationships between power and knowledge, the way knowledge is produced, accepted and rejected, what individuals claim to know and the evidence to which they refer . This brings the learners to the stage, and challenges researchers to understand the internal dialogs which admittedly take place in their minds. Such eclectic view of research involves the use of

> several research strategies from a variety of scholarly disciplines and traditions as they are needed in the unfolding context of the research situation. Such an action is pragmatic and strategic, demanding self-consciousness and awareness of context from the researcher. (Steinberg, 2006:119).

The focus of the present research emerged from previous studies, which showed us the need of a reappraisal of the History of Biology used in educational grounds and the way young students interpret and judge evidence which is traditionally seen as persuasive and unequivocally leading to a certain scientific understanding.

SOCIOCULTURAL CONSTRUCTION OF KNOWLEDGE: HEREDITY

This research program began in 1995, when we first studied ways in which people construct meaning about heredity, focusing everyday knowledge and cognition. Cognitive skills are not fixed and fully predictable, as clear cut results of teaching tasks, but rely heavily on *contexts* (Rogoff & Lave, 1999). Although this understanding is not new, it is necessary to admit that there are many different ways in which the "context" can be defined, as it cannot be seen a structure or features of the task or domain of knowledge. The interpersonal relations and cultural aspects, such as values and beliefs, are important parts of the context in which action is embedded.

Social interaction includes cognitive activity, which implies sharing socially provided tools and *schemas* for action on reality, as

> cognitive activity is socially defined, interpreted and supported. People, usually in conjunction with each other and always guided by social norms, set goals, negotiate appropriate means to reach the goals, and assist each other in implementing the means and resetting the goals as activities evolve." (Rogoff & Lave, 1999: 4).

In the sociocultural perspective cognitive activity is not a lonely and purely logic mental task, but rather a two-leveled process which makes use, on the one hand, of tools for cognitive activity (such as scientific theories) and practices socially negotiated, both related to the past. On the other hand, immediate social interaction creates a material basis for individual cognitive activity. In simpler terms, when one thinks about **heredity**, there are both historical and socially defined inputs, in the form of school books and medical doctors' discourses, as well as relatives and common people's narratives to explain the reason certain traits reached new generations. There are at least two sources of everyday knowledge, in the form of second-hand discourses, which reproduce other peoples' narratives, including repercussion of media diffusion of news, interviews, reports, etc. However, there are first-hand discourses, which focus on the "own life" experience, with narratives with plenty of evidence, referring to knowledge and beliefs.

Knowledge refers to what people know or understand about something, or in Kantian terms, a method that allows the understanding to apply concepts to the evidence of the senses (*schema*). Beliefs can be found in these discourses, as dogmatic social shared notions, which are very difficult to change using discursive and knowledge-based arguments. Obviously, they may vary according to one's academic background, etc., but they are important parts of what we consider *context* in a wider perspective.

We believe these first-hand discourses are more socially supported and may play an important role for the second-hand ones, which can spread knowledge and beliefs reaching a wider social group. However, both may play an important role in the shaping of the knowledge and beliefs students bring to the classroom. When one is asked to explain the color of his/her eyes, there will certainly be a reference to *schema* socially shared which allows to conceive heredity and possibly pending to the knowledge side. More complex questions, such as the reasons some people live longer than others may tend to be explained in terms of beliefs, such as God's will or luck.

Hunt at al (2001) interviewed 61 individuals belonging to families affected by coronary heart disease and concluded that people did not recognize deaths of distant relatives as evidence of genetic problems in the family, but rather attributed them to pure chance. However, when more than one relative was affected, a different picture appeared, as there was some concern about the number of relatives with heart disease on the same side of the family, and this could indicate the effect of heredity. To build their arguments, people often use counter-examples and they are also used to reduce the perceived significance of risks in the family history.

In an introductory pilot study, we interviewed 24 people who attended a genetic counseling service due to the fact that they had children or relatives affected by deafness. These interviews had taken place before patients and their relatives had attended their clinic meetings. The researcher talked to the patients' parents for about thirty minutes in order to collect their ideas. The interviews were semi-structured and asked participants to speak about the origin of the problem. We identified a number of understandings and beliefs of the causes of medical problems, almost all of them pointing to environment as a causal link, especially during pregnancy (Santos and Bizzo, 2005).

We then designed a research program looking for large families with a dominant trait which could not be easily attributed to the environment. In fact, we studied two large families and found very complex and rich narratives in which inherited traits were seen partly due to genetic transmission and partly to the environment, with plenty of evidence taken from second party and direct contact information. They were clearly first-hand narratives, with substantial quantities of evidence (Santos and Bizzo, 2002, 2005).

KNOWLEDGE AND BELIEFS ABOUT EVOLUTION: FIRST RESEARCH QUESTIONS AND SOURCES

Methods developed for the study of conceptions of heredity (Santos and Bizzo, 2005) were applied to design the research of conceptions of biological evolution. Individuals who belonged to families with genetic diseases would be replaced by people who lived near fossil deposits[,] as sources of conceptions using privileged evidence. The first research question was about history of science, referred to the understanding of deep time. When was a solid structured theoretical framework established, on which grounds? Did it involve sound evidence? Another research question referred to learners: what are their conceptions about deep time? How did they judge geological evidence? What are the social views in their environments related to deep time?

A two-leveled research plan was designed, looking for accounts of the development of the theory in History of Science, and for people who had a privileged contact with geologic evidence. A revision of the development of Charles Darwin's published works and letters was carried out, focusing in the perception of geological time, concluding that, in fact, it paved the way for a deeper understanding of the development of life as early as 1835. Document research stressed an important part in Charles Darwin's writings, showing the relevance of geological evidence for the building of the notion of deep time, which could be important for teaching and learning (Bizzo and Bizzo, 2006).

This firm base was possible due not only to the recognized work of Charles Lyell, but also to the authors he admittedly was fully aware of, and derived directly from the 18th century Italian geology (Rudwick, 2008). Darwin's published work soon after the *Beagle's* voyage, more than twenty years before the publication of his major book, clearly shows that he was dealing with the issue of geological time before his first thoughts on natural selection. In fact, he had been reading Charles Lyell's work, in which he advocated a "modern perspective of geological time". However, one who reads Lyell's "Principles of Geology", as Charles Darwin did during the *Beagle's* voyage, finds many quotations of Italian geologists. They would have, Lyell wrote, "ridiculed the psycho teleological systems of Burnett, Whiston and Woodward", written more than one century before, despite the fact that he was almost certainly referring to the recently published work of William Buckland (1784-1856), who had recently published "*Vindiciæ Geologiæ*; or the Connexion of Geology with Religion explained", in 1820, and also his more recent "Reliquiae Diluviae (…)", published three years later. To some historians, Buckland was actually the creator of the creationist movement.

INTERVIEWS: SAMPLING AND DESIGN

As in previous works, we were aware of sampling decisions in the qualitative research process, and how difficult it would be to define groups defined in advance. We were looking for people who lived in places with plenty of geological evidence of deep time, and who knew this evidence in detail and, in addition, could explain their views in an interview. The *a priori* definition of targeting young students relied on the grounds that they could provide their own personal views, which would be comparable to published works as part of the alternative conceptions' literature. However, it was impossible to know how many young students we were going to find at each place, and how important their narratives could possibly be. Therefore, we had to make use of a strategy of gradual definition of sample structure, regarding decisions about choosing and putting together cases, groups and even institutions in the process of collecting and interpreting data. In the qualitative research literature this process is referred as "theoretical sampling" originally developed in the context of research on medical sociology in the 1960s (Glaser and Strauss, 1967, apud Flick, 2006).

In our case, what could be called a representative sample is guaranteed neither by stratification nor by random sampling, but rather by the researcher's perception of the potential of new insights for the developing perspective. In a first phase, it was possible to judge this potential from the knowledge of geological evidence of the place. The main question for selecting data is: "*What* groups or subgroups does one turn to *next* in data collection? And for *what* theoretical purpose? The possibilities of multiple comparisons are infinite and so groups must be chosen according to theoretical criteria" (Glaser and Strauss, 1967, apud Flick, 2006).

Semi-structured interviews were carried out in three different places in Brazil, with students aged 12-16. One place was in southern Brazil, Formação Santa Maria, in a small town where a petrified forest was found (Mata- RS). Two other places were in northeastern region in the Crato Formation, in the Chapada do Araripe region, in the states of Pernambuco and Ceará, and involved students of the same age range. Interviews were transcribed and analyzed, showing rich discourses with explanations about the formation of fossils.

Conclusions showed that fossil formation processes were seen as short-term ones, some taking hundreds of years, despite the fact that a rich paleontological vocabulary was also present in the very same discourses. Terms such as "Albian", "Cretaceous", "100 million years" were often found, but had weak connection to the conception on fossils life span. Jesus Christ and indigenous peoples were frequently referred to as having lived before those animals and plants existed (Bizzo et al, 2006, full interviews transcriptions can be found in Oliveira, 2006).

KNOWLEDGE AND BELIEFS ABOUT EVOLUTION: NEW RESEARCH QUESTIONS AND SOURCES

During field work in Brazil we had collected data which was not initially taken as important as students' interviews. We had unnoticed evidence of social views about geological time in local culture. Artisans sell rocks with engraved images similar of the fossils. Contrary to the first impression, which would present them as simple counterfeit souvenirs intended to defraud tourists, they are artistic representations, which reproduce artisan's understanding of the meaning of fossils. They would be valuable for their intrinsic beauty of forms. These engravings are sold at the house of the artisan, who is proud to say that they are hand made, showing images not only of local known fossils, such as scorpions, dragonflies and insects, but also *Jurassic Park's* dinosaurs and even parrots, disregarding scale in all figures (fig 1a and 1b). These keepsakes express the local understanding of the meaning of fossils, not as proofs of what life was about 100 million years ago, in high Cretaceous, but rather as beautiful forms engraved in solid stone. The notice that a fossil feather was found there, which is presented in the local Paleontology museum, was not understood as a proof of the antiquity of birds in the region (and the whole continent), but took the form of a present-day parrot (fig 1b). So, what we had captured in students' discourse is part of a socially shared meaning of learned expressions like "million years ago", etc.

Figs 1a and 1b. Engraved images produced in the region of the Crato Formation (Brazil).

One possibility to explain previous results of students interviews pointed to the fact that the popular names of fossils in these three places were quite similar to living species. For instance, the fossil remains of trees in Mata (RS) are called by the same name as the living trees (*araucaria*). In the region of Araripe, fossil fish were named as "piabinha", the same as the living fish in small local rivers, which lose all water at least three months in the year – another feature which was part of the explanations about the origin of fossils. Fossilized insects were also named after living ones, for instance dragonfly ("zig zag") and beetles ("besouro").

The similarities between living species and fossil ones in one place, which we called *paleoisomorphies*, led to new research questions. Similar places with striking differences between present day and fossil fauna and flora could possibly lead to different conceptions of geological time, which we called *paleoheteromorphy* hypothesis. Therefore, another research program was designed aiming at finding historic references of scientific discussions in history regarding the meaning of heteromorphic fossils. In addition, we would try to travel to one of these places known for paleoheteromorphies and interview young students there in order to understand their ideas about geological time. Our new research questions referred to finding paleoheteromophic places in the literature of history of geology; and, in addition, we wanted to know if students' views were essentially different in these places. The new sampling would have to follow some constraints, as we would need to find students of similar ages as previously done. Moreover, as one place was found in Italy, we had to face not only questions of transcribing interviews, but also those related to translation.

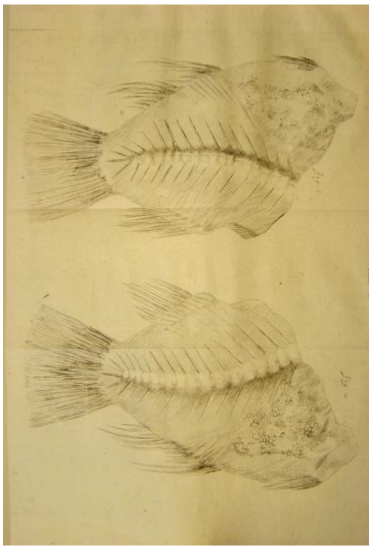
It is recognized that in the context of qualitative research approaches translation involves deeper questions than interviews transcription, as the methodological literature on qualitative research has recognized that the task of generating accurate and meaningful data through translation processes is paramount. The translator is seen as an actual interpreter who "processes the vocabulary and grammatical structure of the words while considering the individual situation and the overall cultural context" (Esposito, 2001,p. 570, apud Marshall & Rossman, 2006). We decided that the same researcher would carry out the translation before the transcription, so that minimal loss of information would be expected.

RESULTS: *NATURE'S INCRIPTIONS DECIPHERED AND READ*

The discussion of the meaning of fossils is a very interesting part of the History of Science and certainly is part of ancient mythologies (Rudwick, 1976). At the end of [XVII] 17th century, as we could see, the Church of England was following theologies which regarded sea fossil remains in mountains as direct proofs of the biblical deluge, and therefore, addressed paleoheteromorphy, as the sea would have brought strange specimens to mountain tops. A turning point can be found in the first years of the 18th century, as debate took place at the French Academy of Science, when Phillipe de La Hire (1660-1718) proposed to regard fossils as living beings which would have lived in the past, as others like Nicolaus Steno (1631-1686) had already proposed, but adding a very special detail. He faced the question of heteropaleomorphy in a quite new approach, without any reference to the deluge, but saying they were transported by water vapor of an underground ocean. Strange fossils would have grown up in the very same places where they are presently found, but inside the rocks, without leaving any external sign. Fossil fish, crabs, lobsters etc. found in high mountains would have been born to microscopic eggs supposedly carried out by water steam all the way up till the hill tops.

This view was criticized by Antonio Vallisneri (1661-1730), who had been a student of Marcello Malpighi (1628-1694), belonging to the school of Galileu Galilei (Rappaport, 1991; Harris, 2009). In his 1727 book "De Corpi Marini che su Monti si Trovano" ("About marine deposits found in mountains"), which brings up de la Hire statements and a study of the petrified fish found in the mountains of Lessinia, in the Province of Verona, which were long known for their extraordinary preservation (Vallisneri, 1727). There are records of the richness of such details, which led many people to describe them as "fish mummies", since the 16th century. A detailed drawing of a petrified fish was included (fig 2a), in order to show that eggs could be seen in the petrified fish, therefore they would belong to egg-producing creatures. In this book, he insisted that the biblical Flood could not account for his ow geological observations, having already developed a reputation as a "non diluvial geologist before writing the first edition of his book. In fact, not only in his book but also in his correspondence, that there existed contradictions, "indissoluble knots", if one compared his own geological views with the Biblical time scale (Rappaport, 1991). Surprisingly, the book received an "imprimatur" stamp of the Inquisition, even if Vallisneri negated the view which attributed the presence of fossils from the sea on the mountains to the effect of the Great Flood affirmed that their presence was instead due to geological transformations, which had led to the rising of lands that had previously been underwater.

The place where the fossils came from was a small village in Italy called Bolca, in the *vicentino-veronese* border, in a place 800 meters above sea level, which is considered a peerless *Konservat-Lagerstätten* (literally "place of storage") or in other words, a place which preserved much of the fossils' details and give a good idea of the whole environment of the past. Without a very good preservation it would be impossible to address de la Hire propositions. There are abundant paleohetermorphic creatures which lived in tropical seas. Palm trees and even cocoa fossils (fig 2b) can be found in that region of the Alps.



Figs 2a and 2b. Page from Vallisneri's book (1727) and a fossil of a cocoa (palm tree fruit) found in Bolca.

This was an ideal place to address research as we had collected data in two other *Konservat-Lagerstätten* in Brazil, namely in the Crato and Santa Maria formations. This was important as we should find Italian students with the same opportunities as the Brazilian ones, who would have had contact not only with fossils, but also with a wider paleontological context. As we will see ahead, many similar details appeared in students' discourse. The discussion of Bolca's paleoheteromorphy can be found in several publications of the 18th century, as Vallisneri's conclusions were confirmed by Lazzaro Spallanzani (1729-1799) almost thirty years later. However, in the words of Charles Lyell:

> A lively controversy arose between Fortis and another Italian naturalist, Testa, concerning the fish of Monte Bolca, in 1793. Their letters, written with great spirit and elegance, show that they were aware that a large proportion of the Subapennine shells were identical with living species, and some of them with species now living in the torrid zone. Fortis proposed a somewhat fanciful conjecture that when the volcanos of the Vicentin were burning, the waters of the Adriatic had a higher temperature; and in this manner, he said that the shells of warmer regions may once have peopled their own seas. But Testa was disposed to think, that these species of testacea were still common to their own and to equinoctial seas, for many, he said, once supposed to be confined to hotter regions, had been afterwards discovered in the Mediterranean. (Lyell, 1835(I), p 77)

In fact, Roderick Murchinson (1792-1871) and Lyell visited Bolca in 1828, and admitted that "the work of geohistory was necessarily interpretative, as nature's monuments could yield little insight unless nature's language could be learned and nature's inscriptions deciphered and read." (Rudwick, 2008).

We have been collecting and reading the production of Italian geologists of the 18th century, which admittedly was the leading earth science of the time. The epistolary debates of Alberto Fortis (1741-1803) (Ciancio, 1994, 2010), and the work of Vallisneri have been very rich sources in order to interpret the ways nature's language was learned in the small village of Bolca, where we performed interviews in the year 2008.

STUDENTS VIEWS: RESEARCH QUESTIONS ANSWERS

Interviews were performed individually in the small village of Bolca, northern Italy, in May-June, 2008. Previous contacts were carried out with the local museum (Bolca's "Museo dei Fossili"), which was visited, and also Verona's "Museo Civico di Storia Naturale" where a larger collection of Bolca's fossils can be found. It is some 30 km away. A semi-structured interview plan was designed and included three parts. The first part had questions about local living species, animal and plants. Other questions regarded local fossils and asked students the name of some of them, showing pictures.

The second part of the interview had questions about three small invertebrates, which were in resin and handed to the students: a large scorpion, and a spider and a beetle which were more or less the same size. We asked students to examine with their own eyes and tell which one was more similar to the spider. The intention of this part of the interview was, first, to investigate their ability to discriminate local living species from exotic ones. The question about the similarity of the spider was intended to see if students answered taking into consideration animal's size, or rather referring to number of legs or any other zoological term, feeling free to give their own opinions. A possible answer mentioning "arachnids" would be taken as a sign that the interviewees were trying to meet researcher's expectations and were not considering their own genuine knowledge.

Students who answered with no reference to formal zoological terms and knew local fossils, were then asked to explain several aspects of their understanding about local geohistory. Students were asked to describe how often they used to go to the local museum, and how they conceived paleoheteromorphy, using examples of known plants and animals. The length of time required for fossilization to occur was another aspect and special attention was paid to any reference to the deluge (which, in fact did not appear at all).

Finally, in the third part of the interview, students were asked to use adhesive labels in order to show their views on deep time, using a pictorial linear representation (timeline), with the word OGGI (today) in one end and the figure of a dinosaur in the other. Red stickers represented local fossil animals, and green stickers represented plants. Once they had placed these two stickers, they were asked to do the same with an adhesive label with the image of Jesus Christ (fig 3a).

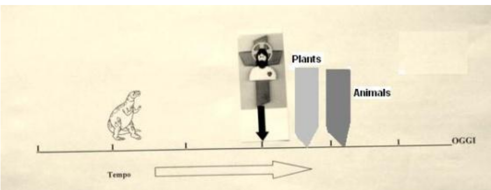
As the village is very small, only six students aged 9-12 years old out of eight qualified for the full interview. The interviews were carried out individually, in their own homes or, as we will see shortly, in the parents' working place. Interviews were performed before their parents; however with no direct eye contact so that the child could not receive positive/negative feedback from his/her parent. Interviews were preformed in Italian (and not in *Veneto* dialect), which is considered the proper form to communicate at schools, and were tape recorded, translated into Portuguese and transcribed for analysis.

One interview can show how rich and original students' views were. Alessia (name not real) is a girl, 10 years old, who was born in the village of Bolca and knows [very well] the local museum very well. She used to play collecting sharks' teeth in a place near her home and knows very well the proofs of the existence of an ancient volcano, which had a crater near the place where the local church is located. The interview was carried out in the place where her father works, in Bolca. In the first part of the interview, she showed her knowledge of local fossils, despite the fact that she did not know local fossils which were not displayed at the local museum. In the second part, which involved the three real size invertebrates on resin, she had as an answer that the spider was more similar to the beetle than to the scorpion, therefore was qualified to go on, as it was a positive sign that she was not simply trying to meet the researcher's expectations. In the first part, she was showed some pictures of Bolca fossils, and asked if she recognized them.

Researcher [showing picture of a fossil plant]: (…) *What about this one... Have you already seen this?*
Alessia: *Yes, but just on pictures* [actually it is not on display in Bolca's Museum, but in Verona's]
Researcher [showing a picture of the fossil fish *Ceratoicthys,* on display in Verona]: *What about this one... Have you already seen it?*
Alessia [hesitatingly]: *Yes. It is the angelfish*.[answer is wrong]

Researcher [showing a picture of the fossil angelfish *Eoplatax papilio* on display in Bolca, considered the most important fossil of the place]: *And what about this one? Do you know this fossil?*
Alessia [positively]: *NO*! [meaning YES!]. *This is the angelfish*! [she is correcting herself].
Researcher: [showing a picture of the fossil fish *Exellia velifer* on display in Verona]: *And what about this one? Do you know this fossil*?
Alessia: *No. This one I do not know*.
Researcher [showing a fossilized plant]: *And this one*?
Alessia: *This is a sort of algae*.
Researcher: *I learned that you know a lot of local fossils! Have you been to the "Museo dei Fossili"?*
Alessia: *Yes, we always go there with schoolmates*.
After answering that the beetle is more similar to the spider than to the scorpio, she was ten asked:
Researcher: *When you went to the* Museo dei Fossili *you saw many plants and animals. Did you have already seen them living outside the* Museo?
Alessia: *No! They do not live here*.
Researcher: *And how was it possible that their fossils were found here*?
Alessia: *Long ago this place was a seashore and there was a volcano here. And the volcano expelled a lot of lava, which burnt animals and some plants.*
Researcher: *Do you mean these animals and plants actually lived here*?
Alessia: *Yes, they lived here*.
Researcher: *They were very different from the one that live here today, weren't they*?
Alessia: *Yes, they were*.
Researcher: *How was it possible that these animals, which were not used to the cold winters you have now, could live here? How is it possible they could survive here?*
Alessia: *Yes, they lived here, 'cause of the volcano, it heated the water of the whole place.*
Researcher: *Ah! I understand. You mean the volcano heated the water, but also the land? The palm trees… We do not find palm trees here anymore… You may have already seen these trees on TV or pictures. They are found only in hot places. Did they actually live here?*
Alessia: *Yes… 'cause of the volcano*.
Researcher: *So… the volcano heated water and land here?*
Alessia [shaking her head positively]: *Yes*.
Researcher: *And how did these animals and plants became rocks? They lived here and there was also a volcano… How there animals and plants became rocks*?
Alessia: *The volcano… There was a lot of lava coming out and it became rocks, and plants and animals also became rocks. But one day, there was no oxygen, and fish cannot live without oxygen. This is why many of them died at the same time. Lava thrown out by volcano formed rocks. Within the rocks there are fish*.
Researcher: *So,* …[thinking] *the rocks in which we find fish were formed by the volcano*… [stating];
Alessia [positively]: *Yes*!
Researcher: *Alright… and there was actually a sea… was the sea here, at this height*?
Alessia: *Yes! It was here, at the top*.
Researcher: *But, how was it possible that the sea had reached this place?*
Alessia: *The whole of the* Pianura Padana [Padan Lowland] *was a large sea*…

The interview explored other aspects, and Alessia was asked to represent her ideas on deep time. Her representation is shown as #2 in fig 3B.



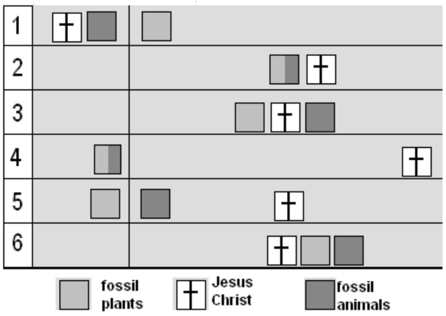


FIG 3a and 3B –Timeline with stickers that students answered (#6) and a summary of the six protocols collected in Bolca.

We were then able to see in objective terms the representation of relative age of the different fossils and time references. Protocol answers are shown in fig. 3b, where we can see several ways in which the local geohistory was conceived. When children speak freely, they show a rich and wide context, generally using a rhetorical expression which is very common in the Italian language, beginning with "*secondo me*" (which means "according to my opinion"). They express complex models, based on very sophisticated evidence available to them, which gives rise to complex intellectual ecologies (Limón, et al, 2009).The oral answers describe a rich knowledge of the Eocene (a term created by Lyell after being there), with two remarkable observations. First, there was no reference to biblical deluge or supernatural explanations; and, second, there was no real acceptance of the description of the uprising of the terrain. Some students declared their knowledge of the "correct" version, but they thought that it was easier to think that the sea had reached that height instead. This is surprising, as we are not facing a religion/belief denial, but a purely rational consideration.

Another interesting model referred to the extinct volcano that can be seen in terms of the abundant basalts that can be found near the local hilltop. A young girl argued that the volcano was once active, and therefore, the local climate should have been hotter; this would explain palm trees and tropical fish found there. There is a surprising coincidence with the arguments used in the Alberto Fortis debate with Testa, as the argument of the microclimate was evocated in 1793 in order to explain local paleoheteromorophy. The "basalt waterfalls" are one of the local attractions for tourists, and provide natural stone bricks, after the action of ice in winter. These bricks were originated from basalt columns, which were described in detail in that epoch (Strange, 1778). Many walls and houses are made with those bricks. This partially explains the reason why the presence of the extinct volcano is so central in youngsters' minds.

As in previous works, we found rich schema, under peculiar ways of interpreting plenty of evidence, and some striking coincidence with similar ways to conceive that body of facts which were used in the past. Our paleoheteromorphy hypothesis showed as not consistent, as there are alternative ways to conceive completely different fossil fauna and flora, without taking into account geological time.

Despite the fact that more research is needed, both in the history of geology and in sociocultural aspects of thinking, results show that geological time is not intuitive and even those who have direct contact with very important and significant fossil remains do not easily construct the notion of deep time. Our conclusion is that there is a need to reconsider curriculum design, and provide students more experience with macro-evolution phenomena, adding new evidence to this proposal as presented in previous works (Dodick & Orion, 2003, Dodick, 2007, Bizzo & El Hani, 2009). Moreover, more attention has to be paid to adult and scholarly scientific definitions offered to students, which can give rise to complex intellectual ecologies in the school context.

REFLECTIONS UPON ENVIRONMENTAL EDUCATION IN TEACHER EDUCATION PROGRAMS: THE CHALLENGE TO DEAL WITH VALUES

Dalva M B Bonotto

Institute of Biology, UNESP - University of São Paulo State

dalvambb@rc.unesp.br

ABSTRACT

The environmental problems are closely related to our actions involving Science, Technology and the Society that affect our relationship with the environment. Therefore, when dealing with environmental education (EE) it is necessary to reflect upon these relations, identifying beliefs and the values subjacent to them, as well as to work with new proposals that can subsidize new visions, relations and practices. The value dimension of EE is evident when it is suggested that new ways of society-nature relations must be built, necessarily based on values in accordance with those changes. In this paper, I would like to analyze accounts given by teachers in investigative training programs, which point out the challenge for them to work with the proposal of changing the society's common values. Teachers showed insecurity and questions about carrying out this task. Some of them clearly exposed their fears of having an authoritarian attitude to deal with values positioning and not living according to the values they bring into the class. These questions and feelings must be regarded as an important issue concerning teacher education programs related to EE and values education, and must be dealt with care.

Keywords: *environmental education; values education, STSE relations.*

INTRODUCTION

Under the perspective of some authors, environmental education (EE) is linked with several contents and proposals that have already been recommended to science teaching, according to the approach of the STS Movement (Santos, 1999; Hodson, 2003; Bonotto, 2006). The environmental issue is closely related to the conceptions and values built by our society, which support our actions involving Science, Technology and the Society, and, consequently, affect our relationship with the environment – the STSE relations.

Then, according to this perspective, to deal with EE we need to reflect on these relations so as not to reduce environmental problems to single out resource management and individual behavioural changes. This means a revolution in institutions, systems, lifestyles and values (Fien & Trainer, 1993), which is necessary if we really want to stand up for the environmental problems.

Since the work with conceptions must aim at reaching a deeper level of beliefs and values that support them, we turned to values education. We need to identify the values subjacent to a common world vision as well as to work with new proposals that can subsidize a new vision and practice by the society. Agreeing with Scott & Oulton (1998), values education is central to EE and it is explicitly necessary to explore these values in school.
A list of these values was identified according to the "Treaty on Environmental Education for Sustainable Societies and Global Responsibility" (Viezzer & Ovalles, 1994, p. 29). This document, directly prepared by civil society during the Earth Summit in 1992, may be regarded as a representation of its values, wishes and understandings. Through it, we can emphasize:

- valuing the life of all living beings (valuing biodiversity and the need for society to reassess its attitude towards all the other living beings on the planet);

- valuing cultural diversity, opening for conversations with other cultures and different forms of knowledge (reassessing the aggravating value placed on Science as superior knowledge and the one which has exclusive right to the truth);

- valuing a sustainable model of society, based on equitable sustainability and quality of life for everyone (reconsidering the direction of technology concerning its articulation with the current capitalist economic model, which has established growing needs for consumer goods, the ones which attain a niche of the population that has been growing smaller and smaller);

- valuing responsibility, solidarity, cooperation and dialogue, which make possible everyone's participation in building up a fair and balanced society, where one can participate in the decisions that affect everyone, a task no longer considered exclusive to specialists, scientists and governmental authorities.

Under this perspective, it is necessary to include in EE educative practices with those values in addition to tasks related to other contents, considering that we do not learn and teach values in the same way we learn and teach knowledge and abilities (Zabala 1998; Ercilla & Tejeda 2004).
However, in Brazil, besides the difficulties to treat EE in schools, we must add to this the non-familiarity of the teacher when dealing with the value content in education as a whole. In fact, the difficulties in focusing on value content and ethical questions involving science teaching and EE have been pointed out in the literature by different investigators around the world (Layton, 1986; Vercher, 1992; Ballantyne & Packer, 1996; Levinson, 2002; Oulton, Dillon & Grace, 2004).

Taking into account the re-emergence of values in Science Education, Corrigan, Dillon & Gunstone (2007) presented different authors who discuss the subject, pointing out this work's possibilities and limitations. When treating the implementation of a curriculum with such emphasis, several of them have called attention to the challenge that it represents to teachers (Hildebrand, 2007; Dillon & Reid, 2007; Ratcliffe, 2007), indicating an important issue to be included in teacher education programs and in investigations seeking to illuminate how to deal with this particular challenge.

THE RESEARCH

Considering this problem, in the last years, I have elaborated and developed teacher education programs that deal with this theme – EE and the work with values – investigating the teachers' learning, under a qualitative research approach (Bogdan & Biklen, 1998). Using a line of inquiry that is rich in descriptive data, focus on individuals' perspectives and interpretations of their world (Miles & Huberman, 1994), the investigation can show aspects of the process that could not be perceived by using a quantitative approach. The research results are concrete aspects that can be used to confront with others in similar contexts, encouraging other researches in the same direction.

I have already organized and carried out three teacher education programs that took place in a city in the countryside of São Paulo state, Brazil:

1- one in-service program in 2001, directed to eight primary-school teachers (7 to 10 year olds), who worked in a municipal school network;

2- one pre-service program in 2004 and 2005, directed to approximately one hundred twenty future science and biology teachers, students of a Biology University Course which prepare them to teach classes in middle and secondary schools (11 to 17 year-olds);

3- one in-service course in 2008, directed to six science and two language middle-school teachers, who worked in the state school network teaching middle classes (11 to 14 year olds).

In these three investigations, my goal was to investigate the teachers' learning in dealing with this topic (the environmental education and its value content), pointing out relevant aspects involved in the apprehension of the subject and its incorporation in their classes.

The data was collected from the different written activities I had handed out to the training teachers, from the teaching plans they had to prepare (during the meetings we had) and teach to their pupils, as well as from the researcher's notes I made after these classes. In the case of the 1st and 3rd programs, I interviewed the teachers in both programs and videotaped the meetings in the 3rd one. The same questions are brought up to the teachers involved in the semi-structured interviews to gather descriptive data in the subjects' own words.

Based on the data collected and after consecutive readings, I extracted the key points that are grouped into similar ideas. By this qualitative data analysis (Bogdan & Biklen, 2006) I could identify some aspects linked with the learning of value content in the environmental issue.

In this paper, I will focus on one group of these aspects, referring to the uncomfortable feelings and queries the teachers had, representing the challenges that they faced while trying to work with the change of the world's vision and values. Is the teachers' vision of science and scientists coherent with the changes that are indicated? How do they evaluate the technological products they themselves consume? How can they educate considering different values from those continuously showed by society? How can teachers educate in values if they themselves are not a good role model? Finally, how can they teach something that they found out has not been learned yet?

I observed these questions clearly emerging during the reflections on the relation between the environmental question and the capitalist and consumerist model of our society, the influence of science and technology in this process and the deep changing proposals of this model.

I will discuss these problems grouped under three closely related categories, presented as follows.

Difficulties on a personal level

The invitation to modify traditional practices, dealing with a changing of conceptions and values to construct a new model of society, is not an easy matter for anybody, including teachers. After some discussions, teachers showed to be insecure and doubtful in their accounts. This mainly occurred when they reflected upon the intensity of the necessary changes and how our daily actions – including the personal ones – are distant from those considered more appropriate, as we can see in the following reports:

The present-day activities showed how difficult it is to change. Is it possible? I saw that all these things are already part of our culture and they represent a habit acquired before our birth. I particularly adore technology, new things (...) (teacher V, 1st program).

Teacher AM – *Do you buy only what you need? I buy 100% of what I don't need!*
Teacher G - *I keep thinking: To what extent can I revert this situation?*
Teacher AM - *Ah, I think now I can't. I can't stop buying… I can't get rid of what I already had* (3th program).

The relationship between the environmental problems widely broadcast and the model of society of which we are (generally) representatives did not seem to be clear to some teachers. They reacted as though they were surprised by this "discovery," according to what one of the states of one of the teachers:

(...) we are always reminding our students of the nature preservation question, but we never associate it with our well-being, our daily routine (teacher L, 1st program).

Seeking to clarify the teachers' own values and conceptions, after an activity with puppets, we simulated a scientific meeting in which the emerged vision of science and scientists was discussed. One primary-school teacher identified, and very clearly expressed, the difficulty she felt modifying her vision of a scientist – an unusual and special human being:

I liked making the scientist puppet, but I confess that I am still bound to the conception of a scientist as someone distant from the actual world (...) (teacher R, 1st program).

These problems have already been identified by other investigations. As Ratcliffe (2007) and Hildebrand (2007) have indicated on referring to science teachers, the emphasis on values in the classroom requires that teachers reflect on their own values, which is not a comfortable process. Hildebrand (2007) also adds that the change required is related to the level of value-conflict that educators "can tolerate in their own values schema" (Hildebrand, 2007, p.58).

Concerning this question, I find important to bring here the reflections of Oulton, Dillon & Grace (2004) dealing with controversial issues. These authors indicated that to deal with controversial issues, it is necessary to explicitly take their nature into account. They emphasize, among other aspects, that "controversial issues cannot always be resolved by resorting to reason, logic or experiment" (p.412), because in the case of the moral dilemmas involved, "they have an affective component," so, "suggesting that a person's stance may be changed by rational argument is simplistic" (p.417).

Also considering science classes, Aikenhead (2006) pointed out that teachers' values, beliefs and ideologies must be in harmony before a teacher teaches subjects related to these aspects. But how can we reach this condition? Is it possible?

Oulton, Dillon & Grace (2004) suggest that controversial issues may be resolved as more information becomes available. I would add that to deal with these delicate feelings and discomfort we must be attentive and try to create in the classes a confidential space of reception, which is fundamental to build an atmosphere of confidence and freedom. That would facilitate the exposure of questions, conflicts and discomfort on the part of each teacher; thus constituting a group process that may help one another to clarify and work on their conflicts and visions, mutually supporting one another.

This aspect was shown by two teachers when I requested the group to point out aspects of the course they found relevant right after the end of the first teacher education program.

Teacher L-… for me, it was the discussion that always took place among the group. The fact that we were always exchanging ideas on the theme...
Teacher R-... a common [space].
Teacher L-... talking about our questions and afflictions.
Teacher R- I guess it was like this, then the question about affection would arise; because it grew really strong. Because it was like this: one supporting the other..." (1st program)

At the same time, it is important to remember that such space is crucial in the process of construction of (new) values we want to see implemented in society, of which teachers are part. When considering that, according to a Piagetian constructivist-interactivist model, values are built up from the projection of positive feelings an individual makes on objects, people and/or relationships (Araújo, 2001), there must be a warming atmosphere for teachers to both reevaluate their conflicts and be able to build up such values.

This is an aspect to be properly addressed in teacher education programs concerning EE, making it possible to handle the anxieties arising from the aim of favoring the intended changing process.

Difficulties considering the opposing influences brought by students Alongside the constraint when identifying the need – and difficulty – for them to change, many teachers showed a similar sensation when they thought about working together with the students:

We can not predict; it is difficult to put it into practice – sustainable development (...) This job is much too difficult. I frankly don't know how we teachers can bring such an advance in our students' lives (Teacher P, 1st program).

While working with her pupils, one of the middle-school teachers explained her difficulties and efforts tackling the consumerism aspect of the waste problem: according to her account, the pupils had a vision impregnated with the idea of only recycling things, and did not easily consider the question of reducing our consumerist attitudes, perhaps a hidden positioning in our capitalist and consumerist society.
One year after the 3rd program was concluded, she was interviewed; and this is the response she gave to this question:

(...) When I worked in the Project, I felt they [the students] *were reluctant, they didn't want to talk about the subject, because it is something that hurts! Because you saw all this question* [about consumerism] *that was dealt with in the text, the song, the movie… it touched, right? It touched*

because that's what it does! (...) and then, when you reach the point of 'I,' what 'I do,' what 'I am like,' [if] *I don't do the same, ah... so what? 'Not me, teacher, no way, you know! Do you think I'll stop buying candy?' So, there is a lot of talking, but when it comes to attitude, very few people are into it! That's a huge problematic issue* (Teacher E, 3rd program).

Dilon & Reid (2007) also showed, in a statement of a teacher investigated, her sadness about the behavior of the children they receive in an EE Centre, "so out of sorts with themselves and their planet" (p.87).

It is necessary to be clear about the difficulties and limitations of any educational activity, mainly when, in the case of EE, we are willing to foster changes in light of the present life style.It is also convenient to bring about reflection on the procedural character of education in these dispiriting moments. Such reflections I presented to the teachers in the 3rd program and, from this stimulus, they started to talk about several experiences they had, remembering situations in which they clearly realized the positive influence they had on several students.

So, when working with values, I consider that it is very important to recognize that the possible changes are neither easy nor fast (we cannot try to achieve total control and absolute success of learning). Additionally, as Hildebrand (2007) says, "We cannot easily 'test', in the conventional manner, or even 'assess', in a more authentic manner, whether or not our students have learned the values we intended in our curriculum statements "(p.46).
This must constantly be explained in teacher education programs, thus helping teachers to forecast their work possibilities more clearly.
This message, mentioned again and again in the teacher education programs analyzed here, due to the repetitive dispiriting moments, reappeared in Teacher E's account, when she was interviewed:

(...) it won't work either; for instance, walk towards a student and tell him that he cannot consume anymore, you know! There's no way to do that (...) I guess [the consumerism question] *must be constantly discussed; it is not in a one-month project that you can* [solve] *that, you know. (...) You've got to keep trying. Who knows? One day, for instance, you have forty* [students in a classroom], *if one or two there have a different idea, or at least, little by little, pay more attention to this consumerism question, to what society requires from each one of us, I guess it's a beginning!*
However, so that it can be a work, to get good results, it would have to be a goal of the school, as well as of everyone in that school (Teacher E, 3rd program).

From personal to pedagogical difficulties in teaching
Accompanying the referred difficulties, I could once again note the uncomfortable feelings and statements of the teachers when facing the task of teaching their pupils about the EE proposals. Several teachers pointed out to the question of not living according to the values they bring to class, not seeing themselves as role models regarding the pretended values, which would make their action difficult:

(...) the student can see it when you're talking about something you believe in or when you're simply talking about it (...) if you talk about it, they question you; they can realize when you're telling the truth or if it's something like, "Let's say we cannot consume." And then I show off my last-generation cell phone; they're very critical of it (Teacher G, 3rd program).

This concern has a reason for being. It is widely accepted that one of the ways of values education is through the real example we give. Puig (1998) regards the role model as one of the ways from which value guidelines – principles that rule a social group's ways of life – are expressed. The models "show the possibility of values, suggest concrete ways of life that both express and initiate processes of encouragement, adoption and invention of ways of living and being." (p.202)

Thus, how can we deal with this impasse: teach about something we haven't (yet) experienced/learned? Assuming that the teacher also places him/herself in the position of learning in light of this situation, the clarity that working on values is typically a collective, long-term task may lead the teacher towards a less dispiriting posture, both in relation to him/herself and in front of the students.

Again, I realized that most of those teacher's questions were connected with a vision that changing is not a continuous process, being expected an immediate change, i.e. there are inadequate visions and practices, on the one hand; practices contemplated, on the other hand, and people should simply go from one side to another quickly and completely.

This reflection was introduced and discussed in the teacher education programs, and then reintroduced by teachers G and E when they were interviewed:

(...) *then, I guess we think it over and bring it into the classroom, and start to reflect, you know* (...) *and that happens here in the program; sometimes you pick up something you were going to throw into the garbage and say, 'how can I throw it away if I am telling my students not to, you know? I guess it was very productive* (Teacher G, 3rd program)

(...) *I haven't changed completely; no one does, right? But I started to see some things that I didn't before and I even... umm… started to police myself about certain things about consumerism that I didn't do before. It is difficult for you to change, though. There is a whole system involved. It's not because it's difficult to change that you won't change, you know!* (Teacher E, 3rd program)

Besides this question related to working with the students, I highlight another difficulty that has arisen in these analyzed experiences, in terms of the insecurity it caused to the teachers. Several of them clearly exposed their fears of having an authoritarian attitude towards the value content of the subjects they were teaching.

Three teachers participating in the 1st program expressed such concern when they were questioned, before the course started, about the ways in which they developed the values education task.

In the second program, this question also represented a difficult matter to the future teachers. After the first presentations about values education, practically all students pointed out in a written assignment that it is such a delicate theme and that it should not be imposed. After several classes, one of them put forward:

Values education is a difficult task, because sometimes we do what we cannot. The education that I received has imposed opinions and then it is not easy for me to do it differently (F.A.K, 2nd program).

This dilemma concerns the problem of universality *versus* relativity of values, one of the greatest discussions involving the values education theme, which ends up causing conflicting situations for teachers when it comes to the way they behave in their classes. The fear of indoctrinating and, consequently, trying to be neutral, already described in the literature, sometimes proved to refrain teachers from working with values. As Scott & Oulton (1998) have already explained, "presenting pupils with a balanced view seems to be taken as fundamental to the pedagogy, but there are some dilemmas here" (p.219).

We consider that values education is the way to avoid extremist standpoints; so, when it comes to judging and choosing values, not everything is equally valid, a fact which must be pointed out (Puig, 1998). From this perspective, we can and must determine some valuable principles that may be turned into guidelines for judgement and human behavior, principles which can and should be introduced into the education process. That is the case when we work with environmental values, already listed in this paper, to which the teacher should be committed.

According to this positioning, Scott & Oulton (1998) discuss about the necessity and benefits of teachers to explicitly declare the environmental principles. Oulton, Dillon, & Grace (2004) encourage teachers “as much as possible to share their views with pupils and make clear the way in which they reach their own attitude towards an issue” (p.420).

Of course it is necessary to recognize that it is not an easy task. As Scoot & Oulton (1998) have already pointed out that “this is difficult enough when focused on relatively straightforward issues as litter or recycling, but impossibly complex when it comes to more abstract, large-scale and remote issues such as acidification or global warming” (p.219). The opposite difficulty has been presented in other investigations, in terms of leaving open questions to which a correct or more correct answer cannot be determined. Ratcliffe (2007), investigating two teachers in a project that emphasized the explicit work with the values dimension of science, pointed out the difficulties they had developing class discussions about the conduct and nature of science. The teachers tended to try to confirm the ‘right‘ answer or to avoid the discussions because there may be many valid answers, though the situation is seen as too complex to consider. It happened “as if they see engaging students’ overtly in considering evidence and making value judgments as a mine field of relativism where anything goes” (p.123).

Therefore, the question of the teacher’s neutral or committed behavior towards values presented in class requires great sensitivity and a good training from the teacher in order to avoid the prejudices that radical positioning can promote on both sides of this dilemma. Being attentive is really necessary “so that neutrality does not mean abandonment and that commitment is not turned into heteronomy” (Puig, 1998, p.234).

FINAL CONSIDERATIONS

All these challenges here presented are important issues to be considered in teacher education programs directed to EE. Fears, insecurities and dispiriting reveal the affective dimension that spans not only values content but both concept and skill-related contents of learning. However, generally the last two constitute the emphasis and interest of educational institutions, showing to be more tangible and liable for intervention, while the feelings dimension remain hidden. But when dealing with values content, it strongly emerges and shows us that it can not be disregarded.

Actually, it is not easy to deal with values and the feelings dimension they hold. In this paper, I tried to reflect on some possibilities of conveying it, with no intent on exhausting the subject, nor disregarding the need for offering information and discussing the conflicts, which has already been indicated in the literature. I am only sure of the fact that this dimension cannot simply be ignored, mainly when dealing with building up values, a process in which affection plays an important role (Bonotto, 2008). I thus agree with Gayford & Dillon (1995), who have already pointed out that a simple concern about knowledge and conceptual understandings in teacher education programs denies the role of emotions, and the wider aspects of "knowing" that should involve considering it too.

To conclude, EE implies a challenge to change world's visions, values and practices, a learning process that involves all citizens of the society, including teachers. This must be considered and carefully exposed to them, helping the teachers to deal with their feelings and expectations. But, if we are to point out our incoherencies, which can bring us discouragement, it is necessary to point out the small achievements, step by step, which show us that it is neither *easy* nor *fast* to construct a new world, but it is *possible*.

ABSTRACT

For the children who are our future; by offering an environment to discover happiness and excitement of experimentation, to improve and develop their verbal, analytical and scientific thinking skills also science curiosity and interest; ensure to children future continuity and communication with science and technology are among the targets of science and community projects. Therefore at this study; "Entertaining Science Summer School Supported by TÜBİTAK" was coordinated for primary pupils who are considered will be most affected from the process, which consist of organized different methods and techniques and sports and arts activities that may be compatible with them. Primary school students who are studying at Kocaeli province constituted the universe of this study. The sample of this study was constituted by 50 students who want to attend school volunteers from among in the fifth grade science students was determined by simple coincidental sampling. In this study; to benefit students from science school and to evaluate interaction of students have been admitted to views of students and their parents. Science Summer School students expressed their opinion shape of they benefited from science school and it had a very positive impact on them and they wanted to spend more time there. Students' parents expressed their opinion shape of their children participated the activities enthusiastically and they like the activities.

Keywords: *Science Summer School, primary pupils, 5. Grade.*

INTRODUCTION

Children with the necessary facilities to deal with science from an early age, developed feelings of excitement and demand in science is seen (Crowther, Norman ve Lederman,2005). Children who actively exploring the environment use their senses to make observations, to order these observations, they are doing and make inferences from these observations. Thus, they develop feelings of curiosity, they talk to their friends and adults, create questions in their mind and they record by making them as pictures, modelling, writing or other activities (Akman, Üstün ve Güler, 2003). Children's natural desire to explore has an important role in the development of scientific awareness at them, and this feeling is the most important resource will benefit throughout their all education life. Ormerod and Duckworth's (1975) literature study stated that 8-13/14 years are critical child's ages to improve behaviours about science by emphasizes the importance of childhood years. Hodson and Freeman (1983), stated to create the behaviour of modern science and scientific image which are offered to children (under 12) and identify their elections have great importance.

Not only schools and teachers throughout all components of society must work for revealed or ensuring continuity sense of this interest and curiosity which starting in the early years in science. These days science education are among the topics no longer primarily interested in the world of science academies. Particularly after the 2000s academies of science in many countries, trying to add education programs as a voluntary activity at preschool and school children to develop their interest in science and science education. Informal environments, such as summer camps, create enabling learning environments may complete the knowledge and skills learned in the schools, research and experimentation. Individuals will be realized that they have to think comprehensive and interrogator for reach systematic information in as such environments (Noel-Storr, 2004). Leon Lederman is the the Nobel physicist who makes the issue widespread throughout the world first. Starting at low level of the economic environment around Chicago, a volunteering-based science education program was implemented successfully.

While science summer camps provide learning environment be more engaging and motivating students, create informal learning environments for students. Camp programs are generally short although intense. When consider the total hours of one-week camp program is equivalent to almost one-two months education at school. This type of science camp is a very good option for environmental learning (Kılıç ve Yardımcı, 2009).

Metin ve Kılıç (2009) ; practiced TÜBİTAK funded science summer school projects in 2008 called "Science, Nature and Children, Three in One Summer Science Camp" and while they searching during proocess, they noted science camp helps students understand the nature of science and explain how scientific knowledge changes.

Purpose and Importance:

Children’s natural desire to explore has an important role in the development of scientific awareness at them, and this feeling is the most important resource will benefit throughout their all education life. Learning science for children will help recognize the world and find solutions to various problems they faced. While science education given especially to younger children, should be guided them; must be provided to learn with having fun and exploring; should be minimized concerns and fears (Cho, 2003; Wilson, 2004). The training in this project includes science and technology activities and music and sports activities which can eliminate children’ fears and concerns that may have acquired in science and math courses, present fun face of science and designed different methods and techniques. Also within the scope of this project uncover and develop students' abilities and interest in science is targeted.

In this research, it is tried answer three questions for pupils’ to take the advantage of science schools and interaction of it.

1: What are the thoughts of pupils about the activities in Summer Science School?

2: What are their thoughts of pupils about the the going on impact of Summer Science School?

3: What are the thoughts of pupils' parents about the changes on students during the activities?

METHOD

A pilot study was implemented with the support of Kocaeli University Research Fund for identify disruptions or problems which may arise during the realization of this project in the summer of 2008. Pilot study made great impact in the province and has been a mediator to emerge a very intense demand. During the pilot study, sample was selected from 5th and 6th grade students. For each grade, 20 students selected through the 5th and 6th grade students whose applications were accepted. Amount of the sample was appropriate for carrying out the study and a program was prepared for two weeks, a week for each group. But, it was decided 5th grade students to be the target group, because of coming into demand especially from the 5th grade and according to observations which were made during the pilot study. This occasion, constituted an important step for the realization of the project.

In this study, the subject projects have been supported by TÜBİTAK. The universe of this study is constituted by primary school students who are studying at Kocaeli province. The sample of this study was constituted by 50 students who want to attend school voluntarily among the fifth grade students who were determined by simple randomly sampling method. The science summer school consist of activities which are organized with different methods and techniques for ensure students benefit the highest level from science school and sports and arts activities that may be compatible with them

In this study the ideas of pupils and their parents were gathered to evaluate the benefits and interactions of science schools. Three methods were used to get pupils ideas. First one was gained with the questionnaire which consists of open ended questions at the end of the activities to determine their ideas about Science Summer Schools.

Second was gained through their writings about their comments in flower class at the end of each day. Third one was gained through twenty students from their school after two months when the Project ended. Parents' ideas were determined from the interviews after all activities were done. The data of pupils and their parents were examined by descriptive analysis method.

FINDINGS

The activities in the concept of TUBITAK's Science Summer School in total 50 students attended and 25 of them from second group. However one of the students was quitted from the evaluation as he become ill. Therefore, there were 49 students in total. 18 of them were girls and 31 of them were boys.

Students present schools are learnt and it's determined that 25 pupils go on their education in 25 schools in the borders of Kocaeli. As their schools show differences and their environments are restricted, it is shown that research has reached the target mass coincidently. Attendees have expressed that 40 of them have never attended such as an activity while 9 of them have experienced before. They have attended science schools, Maths Olympics, various projects and science museum responds.

When we asked the reasons of attending or their expectations from the activities, 32 of the attendants have answered as learning, enjoying while 6 of them have responded they enjoy science and technology. 7 of them liked to spend their free time on experiments and 3 of them hope to find friends and learn something. Only one of them has come for preparation for The Exam of Identifying Students' Levels (SBS).

Pupils' General Ideas About Science Summer School

The data about pupils' responds to the questions if they like the activities or not, if they feel themselves lucky or not, the distinctions from the school are given in this part.

It was asked if they see themselves lucky and happy or not for attending the Science School. f=49 of them have expressed they feel lucky and happy; they have had a very good time here. None of them has given a negative respond to this question. This finding is a sign of reaching the project's target.

In Table 1, the responds of the question; "Are the activities in Science Summer School different from schools' activities? If it is, express what they are?" are given.

Table 1. Pupils' responds' frequencies for the question. "Is there any diffrence between the Science Summer School activities and school activities? If yes mention what they are?"

Pupils' ideas	**N**	**f**
Both lesson and enjoy	49	20
This is better	49	13
It's different. There are more experiments here.	49	10
School is more uneasy	49	1
We do similar things at school.	49	5

In science summer school for f=20 pupils the reason of the difference is both lesson and enjoy while for f=13 the activities are more enjoyable than schools' and for f=10 the reason of the difference is that there are more experiments here. For f=5 pupils similar activities are held in schools, and for f=1 they can behave more independently at summer school.

In Table 2, the frequency of the responds to the question "Do you suggest science summer school to your friends? Why? Why not?"

Table 2. Pupils' responds' frequencies for above question.

Pupils' Ideas	**N**	**f**
Enjoyable, beneficial and lovely place	49	25
I suggest it is beneficial	49	15
Yes. They will be happy	49	8
I don't suggest. We are sad as it has finished.	49	1

f=25 of the pupils suggest as it is enjoyable, beneficial and full of love, f=15 say that they will suggest as it is beneficial. f=8 pupils say that they will suggest their friends as they want their friends to be happy, too.

Responds of the attendants of the question “What have made you the happiest at school? Make a list of them” are given in Table 3.

Table 3. The frequencies of responds to the question “What have made you the happiest at summer science school? Make a list of them”

Pupils’ Ideas	**N**	**f**
All	49	23
Sports activities	49	15
Laboratory	49	6
Space and black hole	49	2
Trip and observation	49	2
Drama	49	1

f=23 of pupils have expressed that they had a good time during all activities, f=15 of them in sports activities (swimming and skiing), f=2 of them while watching space and black holes documentaries and f=1 of them had a good time during drama activities.

Responds of the attendants for the question “Which activities did you like or are you interested in most? Explain why?” are given in Table 4.

Table 4. The frequencies of responds to the question “Which activities did you like or are you interested in most? ”

Pupils’ Ideas	**N**	**f**
All of then are attractive	49	22
Space and black hole	49	8
Laboratory, shampoo and perfume	49	7
Examining the living things	49	2
Forest activities	49	2
Electric activities	49	1
Experiments	49	1
Finding trees’ ages	49	1
Water trombone	49	1

f=22 of the pupils expressed that they liked space and black hole documentary, f=7 liked shampoo and cream activity in laboratory, f=4 of them liked sports activities, f=3 of them liked forest and examining living creatures and water trombone.

When their responds to the question “what would you like to see in science summer school? State please” are examined. f=32 of them have found the activities satisfying while f=8 of them wanted more sports activities. F=7 of them wanted more experiment and survey, while f=3 of them wanted more trip and observation.

The Findings About Their Comments in Flower Room

The pupils’ flower room comments about the activities at the end of the each day are presented with descriptive analysis method.

Comments of the first day

When their first day comments are evaluated, 47 of them told that they had a better day then they thought it to be while only two of them told they had not accustomed yet and so they had not enjoyed yet. Some of them expressed that they have experience in a laboratory for the first time so they were excited. In Table 5 the range of the given and liked activities’ frequencies are given.

Table 5. At the end of the first day, the frequency of their most concerning activities.

The most concerning activities in pupils’ comments.	N	f
Activity 1: Let’s do our own perfumes! Creating perfume with Water vapour with Distillation	49	24
Activity 2: Your wonders about light: How does the light move? How to make a kaleidoscope.	49	43
Activity 3: How to introduce sound? Let’s to water trombone!	49	40
Activity 4: Let’s do rhythm instrument, Let’s create rhythm!	49	38
Alternative activity 3.”Let’s write invisible writing!”	24	12

Pupils have expressed that they liked making the kaleidoscope and water trombone most and they learnt much from it; but they did not like perfume activity as they did not like its smell.

Data on the second day’s comments

At the end of the second day when their writings are examined, it has seen that f=49 (all) of them had a very good time and enjoyed their time much and they found the activities interesting. Most liked activities’ frequencies are given in the Table 6.

Table 6. Their most liked activities' frequencies for second day.

Pupils' most concerning activities	**N**	**F**
Activity 5: "Let's make a journey to the world of living things."	49	48
Activity 6: "Shampoo and cream production factory"	49	43
Activity 7: "Sports time; Let's swim and enjoy the moment."	49	46

When the Table 6 investigated, it has seen that f=48 of them liked the 5th activity most. It is seen that living things and nature still is among the most interesting topics for pupils.

Data on the comments of the third day

When the third day comments are examined it is found that for the f=46 students had a good time and they were really happy while f=2 of them had a moderate day and it would be better and for the f=1 the day was a bit boring.

Their most liked activities' frequencies are given in the Table 7.

Table 7. Their most liked activities' frequency ranges of the third day

Pupils' most concerning activities	N	f
Activity 8: "How to make our city's most famous dessert 'Pişmaniye' Let's go to work shop of it"	49	44
Activity 9: "Let's paint our cell and nucleus take a photo of it"	49	31
Activity 10: "Tree dating laboratory"	49	31
Activity 11: Let's do sun buttery"	49	40
Activity 12: "Let's visit to the archaeology ,the ethnography and the underwater museum ship"	49	46

Pupils' general ideas about the activities are positive; however they mostly talk about the visits to the museums. f=46 of them told that they had a good time while some of them expressed that they had been at a museum for the first time. After the visit to the museum, f=40 of the pupils expressed that they liked the activity of "let's do sun buttery". At the end of the day they told that they liked "let's paint our cell and nucleus and take a photo of it." and "tree dating laboratory" activity most.

Data on the comments of the forth day

When the day's comments are examined, f=48 of them expressed that they had a good time and they learnt many new things and they were very happy, while f=1 of them expressed that their expectations were not satisfied.

Their most liked activities' frequencies are given in the Table 8.

Table 8. Their most liked activities' frequency ranges of the third day

Pupils' most concerning activities	**N**	**f**
Activity 13: The Richter magnitude of an earthquake and Let's determine the amplitude	49	42
Activity 14: "How do robots work?"	49	39
Activity 15: "The documentary of black holes"	49	42
Activity 16: "Let's do ceramics about the global heating"	49	40
Activity 17: "We are learning skiing"	49	46

When we examined the forth day comments it is determined that almost all of them liked the activities. When we examined Table 8, the most liked activity is "we are learning skiing on the ice." with f=46 while f=40 of them liked "Let's do ceramic about the global heating". After these activities "the Richter magnitude of an earthquake and let's determine the amplitude" and the "documentary of black hole" activities are liked mostly. The least liked activity is "how do robots work?".

Data on the fifth day's comment.

When we examined the last day of the summer school, it is determined that f=49 of the pupils were so unhappy as the science summer school was over and they wanted come again and they had a really good time. Their most liked activities' frequencies are given in the Table 9.

Table 9. Their most liked activities' frequency ranges of the fifth day.

Pupils most concerning activities	N	f
Activity 18:"The journey of electricity charge"	49	33
Activity 19: "Drama: to protect environment."	49	32
Activity 20:"Poster competition: our creativity is online."	49	37
Activity *21:* *"*Let's plant tree.	49	40

Most of the pupils wrote positive comments about activities on the fifth day, and they expressed that they enjoyed in all activities. However, especially for f=40 of the students, "let's plant tree" activity is liked most.

When we look at the comments about all of the days, it can be said that the least mentioned activities are even talked much about themselves. This is a sign of reaching the targets.

Findings From the Interviews With Students Two Months After the School Had Finished

To determine ongoing effect of “science summer School for Primary Students”, interviews have been done at their schools. The analysis of these interviews is given below.

- “Did you talk about the activities in Science Summer School with your friends at school or street? With whom? How?” questions were asked.

When the responds were examined, they have expressed that they liked the activities and they also wanted to have such an experience. Some of the responds are like this;

Selin: “*Of course, I have talked about it with my teachers and friends from school or street. I have told some of the information when it is suitable or required.”*

İlker: “*I did. I have told them to my classmates. I have told them the activities; I have told that almost all activities were about science. I would like to join there again with my friends. I have told them sun buttery. It was very good*.”

Kubilay: “*I have talked about it with my schoolmates. I told that it was very good and we had a really good time. I want all of my classmates to attend this class*.”

Fatih: “*I have shared my experiences with my classmates. It attracted their attention, too. They told me that I had been very lucky*.”

Sıla: “*I did. I shared my experiences with my classmates. They understood that I enjoyed very much and they envied me*.”

- Secondly, “Have you told about the activities in Science Summer School with your teachers? Which were their departments? How? What are their reactions?” is asked.

When the responses are examined, it is seen that most of them have shared their experiences with teacher and they mostly have talked with their teacher of science and technology. With their science and technology teacher, they had talked about the experiments. Differently, they had shared their experiences with class and visual arts teacher about the poster competition. Some of the responses are given below.

Halit: “*My science and technology teacher was more interested about my experiences at summer school. As a reaction he said “well done” and “I am pleased that you attend it.*” Moreover, I have changed my school, in past there were not any laboratories at my school, but now there is. (It is really enjoyable.).”

İlker: “*I told about the sun buttery and other activities. They were pleased for my attending. They made us to prepare five-minute presentation about the Science Summer School.*”

Orhan: “*Yes. I told about the Science Summer School whenever it was the subject and I still talk about it, I have seen positive reactions*.”

- Thirdly, “Have attending Science Summer School changed your ideas about science and technology classes? If yes, how? ” is asked.

When their responses are examined, all of them changed their attitudes about science classes positively. From now on, they are not afraid it no longer, they have liked it more and they are more interested in it. Some of the responses are given below.

Kubilay: “*Of course! I liked science more*.”

Sıla: “*I didn’t like science classes before. I like it more now. It is more enjoyable now*.”

Halit: "*Maths and Science lessons are always my favourites, yet I have learnt that they are more enjoyable*."

İlker: "*Thanks to Science Summer School, I am not scared of it any longer and it is more enjoyable now."*

- Fourthly, "Has attending a Science Summer Class contributed your lessons at school? If yes, how?" is asked.

Almost all of the students have expressed that they have liked science more and they are not afraid of it any longer. Some of the responses are given below.

Oğul: "*Yes, it has contributed much. I can understand science lessons better. The first unit was about cell. I have learnt much about cell at Science Summer School*."

Mert: "*I liked science classes more. Thanks to Summer Science School. I raise my finger more during the lesson. Moreover, I got 100 from both first and second exams.* "

Fatih: "*This course contributed much to my school. I feel respect and I am grateful to all my teachers. It is absolutely effective. I support my teacher with my knowledge from summer school while my teacher teaches*."

Parents' Ideas

In this section the findings are given from the interviews with parents and their direct speeches are given with the semi structured interviews.

When we asked "How did you learn about Science Summer School?", They have learnt from teachers. Differently, some of them learnt from web sites, headmaster, newspapers, and from their friends in universities. Examples from their statements:

Mrs. Fatma: "*We have been following this project for two years. I have learnt from newspaper. I applied as soon as I saw it and waited for the respond*."

Mrs. Zeynep: *"Our headmaster sent message to us so we learnt it."*

The frequencies of responses to the question "What were your expectations before attending this school?" are given in Table 10.

Table 10. Parents' responds' frequencies to question "What were your expectations before attending this school?

Expectations about the project	f
As we did not have any pre knowledge we did not have expectations	5
Required activities for experiments and researches	3
Learn something new	2
Learning something about other occupations	2
Applications of the written programmes completely and well	1
Activities which will make them recognize their talents	1
Swimming activities As they are interested in swimming	1

When table 10 is examined, it is found that most of the parents do not have any expectations as they are not having any information about the activities. The expectations of the rest of the parents are experimental and researching activities and new information for the pupils, learning about different occupations, applications of the written programmes completely and well, activities which will make them recognize their talents and swimming activities.

The respond of Mr. Murat: "*My son is self conscious. I want this project for him to meet new friends and so he will see that he can achieve something*."

Mrs. Serap: "*I have not learnt ideas of my daughter but she always told that "I can learn something from this school and I can tell them to my friends. And she had such ideas*."

Mrs Ayşe: "*My son was pretty excited. He wants to be a scientist or chemist and even an astronaut. He wanted to learn something about these occupations*."

When we asked "Have your expectations been satisfied?" nearly all of them responded positively. They agreed that their expectations were satisfied.

Mr. Haydar: "*I want stress that our children are impressed much by the experiments. We are all satisfied.*"

Mrs. Ayşe: "*When we examined the programme we wanted all activities to be applied and you did it*."

Mrs. Sevda: *"My daughter said that she wished all our education system was like this.* This is a really important change. It satisfied her more than she waited. She learnt such things that she never expected before. Because there is everything in it. She is interested in experiments but also she likes art, drama, social activities. They learn through joy. It is amazing."

To the question "Did your children mention about the activities at home?" they all said yes.

The respond of Mrs. Buse; "She *told me every day. "We did this and that…" It was amazing. She wrote what she did all day*."

Mrs Aslı: "*When she came back home she always told what she had done all day. "We did experiments, shampoo" she was so pleased with the activities. She showed us what she did in the activities."*

Mr. Murat: "*He told us everything. He told how they caught insects in the forest. Of course we shared with him, too. He never told something negative*."

When we asked "Were they eager to get up early in the morning?" they told that their children had never been so eager to get p early, they came there eagerly.

The Mrs. Irem: "*She is so eager. She counted minutes, seconds. She does not want to be late. She came as eager as the first day*."

Mr Haydar: "*He was eager. Fatih had friends at summer schools with him, they were all eager. They are ready at seven thirty. Why? They liked it. Their other friends and teachers all liked as they want to come. We did not have any problem about it."*

Mrs. Buse: "*Absolutely, she woke up eagerly, and even she was so quick so as not to be late. They say you pay much attention, personal attention and they come eagerly."*

The responds' frequency to the question "Are there any observable changes on your children?" is given in Table 11

Table 11. Parents' responds' frequencies to question "Are there any observable changes on your children?"

Observable changes about children	f
They are more sure of themselves	8
They are more sharer and turn to science	4
She/he is more curious	1
She/He is more eager to go to university	1
He/She is more happy.	1

When we examined the Table 11, the main change is that they are more social and they feel surer of themselves. The respond of Mrs. Eda is:

"Of course there are changes. For example, she was self conscious. She could not speak with others. Now, she tells everything to the neighbours. She could not eat anything when foreigners come. But it is over."

The respond of Mrs. Nesrin is:

"*There are huge changes about my son. He was very silent. He is more active and talkative now."* The respond of Mrs Serap is:

"He is aware that such a project contributed much to him. He can see he is different from other boys around him. He feels better himself. He learnt the significance of education. He learnt the significance of learning through doing it. He felt the self reliance of awareness. He has a different self reliance now."

CONCLUSIONS AND IMPLICATIONS

It was determined that pupils have positive comments like they benefited from the activities and affected positively, they wanted the summer science school to be more longer and arranged again next year. Also, most of the pupils stated that activities increased their self confidence and they could do science experiments easier.

It is one of the results among the Kanpur's Pupils' Science Education Camp is that pupils' are more confident while doing an experiment (Verma, 2007). At the end of Bağcı Kılıç and his asistant's (2009) project "Three in One: Nature, Science and Children" with the help of TUBITAK, it is emphasized that science summer schools provide informal learning, this learning environment is motivating and such kind of science camps is a good choice of environmental earning. In this research children expressed their good feelings, also which is proving. this.
It is determined that pupils have found the summer schools' activities more different, enjoyable, amazing, and beneficial. the researches on the space literature have proved that these kind of projects provides larger horizons for reaching to education opportunities and to join pupils from different cultures (Demirel, 2006). Moreover, pupils ,thanks to these activities, find the opportunity to share their creativity with their friends, teachers and the other parts of the society and these activities provide positive effects on the pupils (Tezcan & Gülperçin 2008).
Moreover, result of activities during project, the curiosity and interest of the children are tried to be determined to science and environment. It is found that this attention have lasted two months after the project. the different researches proved that the learning sources other than formal learning make learning more productive. it is seen that the variety of the activities which pupils spend time with and rising their frequencies have made their talents which they learnt at school before have expanded (Gerber, Cavallo & Marek, 2001; hannu, 1993) The parents of the pupils have expressed that pupils came to school eagerly, they have shared their experiences at home after school every day, they wanted to have a longer summer school and they thought it would be boring but they did not.
These suggestions can be put owing to the research results.

To improve pupils' curiosity and attention to science, to improve their reactions with their environment and to gain a positive view towards school, we can use science schools.

Pupils who attended the project can be selected for a science club by science and technology teachers and they can share the activities of the project.

Also it isn't the aim of this project that pupils reflect the knowledge they learned from project to their science and technology course. It was supposed them to develop positive attitudes towards science. And these positive variations will cause directly pupils to like and interested in this course more.

The projects' activities can be used by teachers;

To universalize these Science and Society Projects, academicians and teachers can lecture in-service education.

To universalize Science and Society Projects, a cooperation can be node between primary schools and universities.

Teachers can be supported for preparing projects like this in their schools. So much more pupils can benefit from summer science schools.

REACHING FOR THE STARS: IMPROVING EPISTEMOLOGICAL ACCESS THROUGH UNDERSTANDING STUDENT VALUES

ABSTRACT

Science as a way of knowing and doing is powerfully evident in modern life. The knowledge and expertise associated with it is consequently sought after to promote socio-economic development, even in situations where it may cause conflict with indigenous socio-cultural beliefs and the values associated with them. Drawing on research that investigated the impact of worldview on learning in basic astronomy, this paper considers the relationship between science education and human values in South Africa. It raises the issue of epistemological access in situations of cognitive conflict and suggests that cultural border crossing into science requires an open attitude on the part of science teachers, not just on the part of students. In South Africa the demographic composition indicates a predominantly religious and strongly multicultural population, with the fastest growing churches being African Independent Churches which follow a synthesis of African traditional religions and fundamentalist Christianity. In this context, the unmediated presentation of scientific theories which conflict with socio-cultural beliefs presents a complex set of moral problems which are linked to the effective teaching and learning of science.

Keywords: *Astronomy; cognitive conflict; epistemological access; student values; lecturer attitudes.*

INTRODUCTION

'Knowing' is closely linked to culture. It shapes how people live, it permeates their identity, and it determines how they will respond to new information. In South Africa, 'knowing' is associated with an individual's socio-cultural and economic environment, which may include language, tribal affiliation, schooling, levels of urbanization and economic class. South Africa is well known for its diversity, which is normally associated with race and culture. Yet onto this diversity, as far as science education is concerned, is imposed a one-size-fits all curriculum, which despite falling under the democracy-inspired principle that the existence and presence of 'other ways of knowing' should be acknowledged and valued, continues to follow the standard account of science.

Many of the teaching and learning difficulties associated with science are linked to problems such as lack of resources, poor pedagogic content knowledge on the part of teachers, and poor grounding on the part of students. However, some of these problems are associated with cognitive conflict, which is the result of conflicting accounts of 'truth'. The most commonly known context for this type of conflict is Darwinian evolution versus *ex-nihilo* creation, but similar conflicts are found in Earth Science, Paleontology and Physics. Big Bang theory, Solar Nebula theory and the concept of geological time, for example, are alien to students whose worldview has been shaped by African traditional beliefs and imported global religions.

While there has been considerable erosion of cultural beliefs and practices, accompanied by the adoption of 'western' lifestyles, African ontology is religious, with Africans described as being 'notoriously religious' (Mbiti, 1969, 1989).For the many South African people who view themselves as Christian (i.e. 80% of the population (Hendricks and Erasmus, 2005)), the unmediated presentation of the standard account of science can result in skepticism towards science, or even the wholesale rejection of science. Alternatively, it can lead to skepticism or rejection of their previously held ideas. The latter can have serious implications for students as far as their socio-cultural values are concerned, especially in relation to their home life and cultural community.

While the science education community is increasingly becoming aware that the teaching of science is not value free, science teachers generally, but especially those in the higher education sector, appear to be unaware of the need to engage students to create appropriate conditions for epistemological access. In the interests of improving learning without alienating students from their cultural or traditional values, it is critical in South Africa that science educators honour and respect such beliefs and values, even if they don't hold them to be true themselves.

SCIENCE EDUCATION IN SOUTH AFRICA

A history of inequality

2010 marks the 20th anniversary of Nelson Mandela's release from prison – a momentous year in South Africa's history as it heralded the beginning of a new political dispensation. In the two decades that have elapsed since then, education has undergone massive reform, primarily to address the inequities of apartheid. The single most important purpose of post-apartheid education in South Africa was the de-racialisation of the system. A news feature in *Nature* (Cherry, 2010, 727) highlights the fact that these reform measures were intended to "unleash a pool of talented students who had been denied opportunities under apartheid". However it is clear that most of these hopes have remained unrealized: over the past seven years, matric pass rates have declined by more than 10%, from 73.3% to 60.6% (Equal Education, 2010). In relation to educational inequities, an even more worrying trend exists: in 2008, for example, 99.3% of white learners passed their matric exams, with 68.7% attaining university level entrance passes. For black learners, the pass rate was 56.6% and 13.4% respectively. Indigenous black Africans make up 80% of the population, but in 2006, for example, only 12% of students registered in tertiary institutions were from this demographic group. The graduation rate for higher education is, at 15%, one of the lowest in the world, with the number of white graduates being more than double the number of black graduates (Letseka and Maile, 2008).The article in Nature points out that "since 1994, the government has in theory been committed to ensuring that 'blacks' (a generic term it uses to mean all people not classified as white under apartheid) have had improved access to higher education and research, but this has turned out to be difficult to achieve, particularly in science" (Cherry, 2010, 728). In this article, this is ascribed to the fact that "many black schools in the apartheid era did not offer mathematics and physical science as subjects, initially as a point of policy, and latterly on account of a teacher shortage" (Ibid.).

While these statements are true, they do not address the issue of epistemological access (Morrow, 2009), which lies at the heart of the argument presented here: science, as it is taught and examined at school and in higher education in South Africa, is a western product. Its power preserves it from needing to adjust to fit the context. In this case the context refers to South African students: they are expected to conform to the discipline and failures are ascribed to a lack of ability or aptitude on their part to adjust. The statistics given above speak of the scale of this lack of adjustment, and highlight the need for a different perspective to explain the lack of success in science, especially in relation to black African students.

The problem of epistemological access

Morrow (2009, 78) describes epistemological access as "learning how to become a successful participant in an academic practice". He distinguishes it from formal access, which describes the criteria that need to be filled in order to be accepted into an institution, for example attaining sufficiently good grades at school. Epistemological access, he says, is dependent on the student trying to learn, but in the same way that a coach and high quality equipment can help someone to become a successful athlete, 'it is the athlete who needs to do the running' (*Ibid*.).

In the context of science in higher education in South Africa, what does such epistemological access involve? To answer this question, we need to consider the epistemic values of the students in relation to the epistemic values of science. To do this, we will first consider the development of the new national curriculum and the values it has tried to introduce to honour and confirm all of South Africa's people. This will be followed by a consideration of the history of science in South Africa and the values associated with it, and how these may be impacting on the epistemological access of students. Evidence to support the need for awareness of epistemic values to facilitate epistemological access will then be given from a case study in basic astronomy.

The development of the new curriculum

The standard account of science is universalist: it opposes the existence, for example, of Aboriginal science or African science. However, research in science education, in the context of multicultural classrooms, has led to the well known concept of cultural border crossing (Aikenhead, 1996), which draws on the concept of worldview and argues that all knowledge is human construct and consequently there is no absolute 'Truth'. This relativist view advocates that science teachers should act as 'culture brokers' to help their students effect the border crossings required between their life world and the world of science. Research using this perspective as a framework has shown that the greater the dissonance between the student's life world and that of science, the greater will be their difficulty in learning science (Costa, 1995). As far as South Africa is concerned, it has been made clear that ontological and epistemological differences between African and western ways of knowing have serious implications for Africans in earning science (Jegede, 1997). Research studies in South Africa have confirmed that the lifeworlds and epistemologies of many black African students do not serve as an appropriate foundation for the construction of scientific concepts (Fakudze and Ogunniyi, 2003). Abimbola (1977) has even recorded that African children view science as a "pack of lies". Such views should not, incidentally, be conflated with notions of disadvantage or misconceptions. They are reflective of a knowledge system, i.e. a particular way of seeing and interpreting the world.

At the heart of the new National Curriculum, created and implemented in the years following 1994, is the constructivist notion of the importance of prior learning. South Africa's population, which currently comprises 80% black, 9% white, 9% mixed race and 2% Indian (SAIRR, 2010), is made up of a vast diversity of cultures, evidenced by the fact that South Africa has 11 official languages. Underlying this cultural diversity is a wealth of different 'ways of knowing', underpinned by cultural artefacts such as language, customs and belief systems. In conceptualizing the new curriculum, the need to recognize and ascribe value to these ways of knowing led to the inclusion 'of the need to acknowledge, recognise and value' these many different ways of knowing, as one of nine principles on which the new curriculum was developed (Department of Education, 2003). This principle is especially important and challenging in the science curriculum, which is made up of the standard western account of the physical world and reflects the dualism that characterizes western science at the level that it is presented at schools.

The new South African curriculum is special in that firstly, it recognizes the existence of Indigenous Knowledge Systems (IKS) and secondly, it requires, in the spirit of redress and equity, that these should be acknowledged and valued in the classroom. The transference from principle to application in the classroom is fraught with difficulty, however, especially for science teachers. One of the main problems arises from the fact that no conceptual guidance is given to teachers regarding how they should introduce or include indigenous knowledge in their teaching (Gundry and Cameron, 2008). The most unproblematic way to include IKS is to 'find' science in cultural practices. For example, the recognition of science (in this case cloud seeding) in the traditional practice of burning of tracts of natural land 'to create smoke to call the rain clouds' at the end of the dry season in the Lowveld areas of Mpumalanga (famous as the home of the Kruger National Park, and site of huge tracts of land being burned by local people to create grazing for their cattle) is exciting for those who seek relevance for African students in an otherwise western account of science. However, while the inclusion of such examples has been shown to stimulate interest in science (Manzini, 2000), they tend to be treated as curiosities or as subsidiary to the enterprise of 'real' science. In contrast to this, intractable problems arise when the knowledge associated with IKS is challenging from an epistemological point of view. Darwinian evolution, for example, which was formally included for the first time in the secondary school curriculum in 2008, is challenging for many teachers and learners. African traditional creation beliefs are varied but invariably involve a creator, and for those who have embraced Christianity, the notion of a created earth supports a fundamentally religious epistemology. The dualism of western science, where the physical is clearly separated from (and sometimes scorns) the metaphysical, does not fit comfortably with African philosophy: for the African, "to be is to be religious in a religious universe" (Mbiti, 1969, 256).

The development of science in South Africa

The development of science as an enterprise in South Africa provides a fruitful view of the philosophical exclusivity and universalist perspective that tends to be associated with science in higher education in this country. The fact that science was brought by European colonists and was predominantly a colonial pursuit may account for what Dubow (1995) has termed 'intellectual racism', or in the context of science, 'scientific racism'. Dubow, a historian who has studied the history of science and apartheid, suggests that scientific racism

> "initially arose out of the post-war anti-racist consensus which utilized the findings of modern population genetics to declare that 'race' was a biological 'myth' whose meaning was socially constructed rather than intrinsic. Increasingly framed as a social issue, the problem of racism came to be sloughed off from the concerns of traditional science and was absorbed instead into the domain of social science where it took shape as the study of 'race relations'" (Dubow,1995, 3).

Science was thus released from relativism, with science lecturers able to pursue their research and their teaching without having to consider issues such as the impact of worldview on teaching and learning in their discipline. Dubow highlights the sense of unawareness that accompanies much teaching in higher education by pointing out that "so much of popular racism exists as a matter of unstated assumptions and unthinking responses; it often has more to do with the *absence* than the *presence* of considered thought" (Ibid., 7). For scientist and science lecturers who are required to teach and perform research in their own field of study, work expectations and pressures and the relative value of teaching versus research in most South African universities precludes engagement with the messiness of educational research in science faculties. Science lecturers consequently attend to issues of curriculum and content rather than to theories of learning. Poor pass rates are more easily ascribed to a lack of suitable preparation at school, or inappropriate admission criteria, than to problems caused by differing worldviews and inappropriate prior knowledge.

However, science education research in multiculturalism points out the need to acknowledge the existence of other worldviews in multicultural classrooms and the benefits to recognizing the need for culture brokering. But cultural border crossing is not limited to the customs and social practices associated with IKS,. It has also been associated specifically with religious beliefs (as shown, for example, by Jackson, Doster, Meadows and Wood (1995), Roth and Alexander (1997), and Shipman, Brickhouse, Dagher and Letts (2002)). Liwane (2010) notes that “African people are collectively united by their religious experience. It is entrenched and pervasive in virtually all aspects of their lives on a daily basis”. In South Africa, religious belief systems are made additionally complex through the synthesis of African Traditional Religious beliefs being interwoven with the belief systems of imported religions, notably Christianity (Cameron, 2007). The strongest of African values derive from this deep religious base and the associated concept of ‘ubuntu’, the cardinal belief of which is “I am human because you are human”. From these issue all the fundamental values of an African worldview: group solidarity, conformity, compassion, respect, human dignity and collective unity (*Ibid*.). Cultural practices such as those that fall under the hold-all ‘IKS’ form one aspect that shapes an African worldview. But the values that are associated with an African worldview are tied to a religious epistemology.

The history of the development of western science is also a history of the split between science and religion, and this is embodied, in the context of higher education, in the separation into faculties which are distinct and separate, i.e. Humanities and Sciences. Science education straddles the two, but most lecturers in ‘pure science’ have not been exposed to the challenges of educational research and consequently are unaware of the potential clash between the students’ epistemic values and the values of science. While the curriculum battles that have been fought in the United States of America are well known, very little has been published in this area in South Africa. Periodically, research is reported in some of the prime international science education journals, yet few discipline specialists, i.e. the science lecturers in higher education, are interested in this literature.

In South Africa, where the majority of the population is Christian, and the fastest growing Churches are the African Independent Churches which practice a synthesis of mainly Old Testament theology and African Traditional Religion, the impact of worldview on learning in science cannot be underestimated.

A PhD research study on learning in basic astronomy in South Africa (Cameron, 2007) provides evidence of the necessity for lecturer awareness of students’ worldviews and their epistemic values in order to facilitate learning. Such awareness enables student participation in academic practice and facilitates the epistemological access which, it is suggested here, is vital to improving success in science teaching and learning.

A CASE STUDY: EPISTEMOLOGICAL ACCESS IN BASIC ASTRONOMY

Geography and Earth Science students at a large urban university in South Africa are required, as part of their first year curriculum, to take a course in basic astronomy to provide a foundation for later courses in Geology or Physical Geography. Since matric Geography is not a requirement for entry into degrees in Geology and Geography, ‘The Earth in Space’ course was devised to ensure that all students completing their first year had the appropriate background knowledge to progress further in their studies. Research over a period of four years into the poor pass rates experienced in this course, but notably in relation to black African students, revealed that students’ epistemic values created barriers to learning regarding particular aspects of the course.

Epistemic values grounded in culture and religion

The findings of this study indicated that students had a weak understanding of concepts such as rotation and revolution. This is not unusual as far as learning in basic astronomy is concerned: a recent review of astronomy education research (Lelliott and Rollnick, in press) shows it has been well established that all over the world, the counterintuitive and abstract nature of the mental models needed to explain these phenomena are difficult to construct. However, it was also shown that for many students some of the theories, notably the Solar Nebula theory which explains the structure and formation of the solar system, and the Big Bang theory, which explains the structure and formation of the universe, were challenging to their beliefs regarding the earth and their experience of it.

The most common traditional belief that emerged from the research held that stars were the 'eyes of the ancestors', who at night watched over their kin and protected them. Interviews with the students revealed that they generally accepted such beliefs to be myths, and were willing - in their context as university students - to replace them with scientific explanations, which were seen as credible and scientifically sound. However, for those students who also saw these theories as undermining of their religious beliefs, the cognitive reaction was frequently one of conflict and rejection. One of the most significant findings in this study was that half the students in the sample (49.6%) admitted to having difficulties in relation to the science/religion debate that was raised by the course. A typical comment was: 'I still don't believe the hypothesis that the solar system formed from matter that accreted together because I think God is the creator of the world and everything that is. Everything we learnt except the climate part was controversial and I don't believe it'. Interviews following a classroom questionnaire suggested that this figure was conservative: when given the opportunity to speak about their reactions during interviews, the students were far more emphatic about their distress.

The issue for these students was that the unmediated teaching of science not only left them feeling overwhelmed - as in "I used to believe the explanation given in the Bible, but now 'Earth in Space' has left me with a big task to do" . The problem was that the 'task' carried risk and consequences for their epistemic values. For students trying to make the learning their own, the task involved a difficult choice: to remain true to their previous ideas, as in: "Science cannot answer everything, so some of the things we can just conclude as: God made it this way and that's it", or reject them and supplant them with science: "I always thought that God created everything but now I find it hard to believe, because the Big Bang theory is understandable". Research in developed countries, notably the United States, has shown a similar spectrum of reaction by students to ideas that challenge their beliefs (for example Roth and Alexander, 1997). In the case of South Africa, however, the conflict is not just related to personal ideas: the rejection of previously held ideas is profoundly consequential in relation to deeply held values related to community and identity: as pointed out by Liwane (2010), group solidarity, conformity and collective unity are hallmarks of ubuntu. Students find themselves caught between two worlds, as indicated by a student describing his concerns about paleontology and the anticipated reaction of community and family: '…they have this belief in African tradition. When they look at the sky, they don't see a scientific thing – the stars are the ancestors looking down on them… (but) paleontology – that's the worst part! 'Cos paleontology is like digging up bones and stuff like that and for them it's like an insult to their ancestors! They believe… how can you dig up someone who is laid to rest, and who is watching all on you? So when you tell them about fossils and stuff like that… they really… they don't want to go there. They think no! no! no! the ancestors are going to be angry at us'.

On the one hand, then, students run the risk, in rejecting the ideas of family and community, of isolation and rejection, as in: 'When I am at home in the rural areas, I believe that all the traditional things work, because I do not want to be ostracized. Because, now, they say…'I believe I am white!'… its very difficult when I go home. I don't – I mustn't – speak English, and that's very difficult because I've been speaking English so much (at university).' On the other hand, rejection of what they were being taught meant that learning was compromised and carried the very real risk of failure. The legacy of pain of 'other ways of knowing' in Africa being considered inferior to western ideas, especially regarding science, and their fear of failure, was evident in the comment: “I know that we don’t fail because we are foolish, but because we get confused with the kind of information we have in our minds”. This is also clearly demonstrated in what was rather a laboured explanation: ‘…they try hard, they go to the library and pick up ‘heavy’ books for a simple explanation for how a star is born. You just have to get it, digest it and understand it. That’s it. There’s nothing hard about that. And then they think – no. Culture just closes them – but then again the person has a right to do whatever they want with their mind. And that’s how they fail to answer the questions properly, and then you bring their grades down. So it’s not entirely that they are lazy or stuff like that… they do try… it’s just that they don’t understand… they just can’t catch that idea.’

Border crossing and epistemological access

The findings indicated that the students who managed to find a way to deal with their conflicting beliefs were the most likely to succeed in the course, but they were few in number. Most experienced what is termed a ‘hazardous border crossing’ (Aikenhead, 1996), indicating that their chance of success was compromised. Comments that illustrate the cognitive conflict experienced included: “To me, a lot of the things in the course sounds very unreal. As a result I have had conflicts with previous and new ideas. Most of the time, I personally favour my previous ideas”, and “…like me, I don’t know about Big Bang till I do Geology at university this year. For people who are not doing Geology, when I try to tell them about the theory they think I am joking or it’s a fairytale”.

The response to the findings of this study was that in subsequent courses, ‘the elephant in the room’ was made explicit: the introductory lecture focused on the notion of ‘other ways of knowing’ and the fact that in the new South African curriculum, these were to be acknowledged and valued. Multiculturalism and diversity were to be celebrated, with due recognition being given to the existence of different epistemic values. Students were invited to share in the scientific explanations but recognize that traditional and religious explanations had their own intrinsic value. Discussion on the nature of science and the value of other ways of knowing was encouraged. The simple and respectful acknowledgement of difficulties related to epistemic values, particularly regarding understanding and engaging with evolutionary theories set the tone for a much deeper engagement with science. As one student put it: “If you are prepared to come and ‘play’ in my world, I am prepared to come and ‘play’ in yours”.

Aikenhead’s theories of cultural border crossing in science and the need for teachers to act as ‘culture brokers’ (1996) is well known. Jegede’s theory of collateral learning, which describes how students compartmentalize their knowledge (1995) is also well known, especially in the science education literature. The science / religion debate literature is vast, and there is a growing literature on IKS in South Africa. The problem is that all these areas represent disciplinary silos, which exist separately from the disciplines of ‘hard science’ which form the courses that students take at university. In courses in the biological, physical and earth sciences, culture brokering would be appropriate in aspects of physics, paleontology, archeology and astronomy, and of course in biological evolution. Such ‘culture brokering’ or ‘bridge building’ (George, 1999) does not need to undermine the academic status of such, which are esteemed for their role in providing access for graduates into the global ‘academic lingua franca’ of knowledge. Rather, it is to facilitate epistemological access, to provide a ‘way in’ to an engagement with science. This is particularly pertinent in South Africa, which enjoys the global heritage status of ‘The Cradle of Humankind’. For students who would otherwise struggle in silence or isolation because they are too afraid to challenge, or because their culture of respect requires that ‘you do not challenge your elders and teachers’, efforts by lecturers to build epistemological bridges could make a substantial difference.

VALUING VALUES AS A WAY TO FORWARD LEARNING

Morrow has pointed out that in South Africa "we all carry the burden of a manifestly unjust past" and that "given our history of political exclusion and the strong need to expunge that history, redress must be high on our agenda in the years ahead" (Morrow, 2009, 70). The point being made is that this redress must include recognition, in the context of multicultural classrooms, of the reality of different worldviews and the epistemic values associated with them. Awareness of the necessity for respectful recognition and acknowledgement by lecturers of such differences could help students to resolve cognitive conflicts rooted in their values rather than in their academic ability. Instead of reacting defensively or retreating, students may then be encouraged to explicitly grapple with problems related to their values. However, it must also be noted that an increasing number of black students have become 'secularised' from their traditional culture. While the need for epistemological access is consequently not necessarily applicable to all students, the opportunity to learn about different cultural values and perspectives is still relevant in the context of South Africa's diversity.

In the higher education environment, which is so tied to the 'institutionalization and professionalization of knowledge in South Africa…and to the relationship of this process to developments overseas' (Dubow,1995, 11), it may take accusations of 'scientific racism' to alert lecturers to their need to become aware of issues related to worldview and epistemological access. The typical academic culture of 'sink or swim' is counterproductive and it makes sense to follow Liwane's suggestion, that "conceptual frameworks of strategy and ideas must try and make reference to the African religious and cultural experiences if effective transfer and adaptation are to take place" (Liwane, 2010). This does not mean that lecturers would compromise the science they teach. Rather, it means that in awareness, they would be paving the way for more students to gain access to science. In South Africa, the balance of costs, i.e. a shift in perspective for lecturers, against potential engagement rates for students, is such that we cannot afford to miss any opportunity which can lead to an increase in the number of graduates. 'Epistemological access' is a concept that allows for the 'Africanisation' of science without compromising the final 'product', i.e. science graduates who are able to cope with ambiguity and contending theories.

CONCLUSION

This study has shown that in the context of South Africa, traditional and religious beliefs create a double layer of objection to science that is in conflict with students' beliefs and values. The focus of this paper was to draw attention to the role of the lecturer in providing epistemological access by explicitly acknowledging the existence of multiple worldviews in situations of potential cognitive conflict.

In their own journeys to becoming scientists and teachers of science, university faculty may never have been challenged themselves in needing to come to terms with different ways of knowing. However, in a country such as South Africa, which is characterised by cultural diversity, the unmediated presentation of science as universal truth comes at a cost to a country that aspires to increase education levels and participation.

The concept of epistemological access is one that may be fruitfully employed in a situation where the need to grow the number of black graduates is critically urgent. The requirement is that 'hard scientists' shift their gaze from their own pursuit of truth to considerations that affect learning. In the interests of producing successful 'athletes' (to borrow the analogy used by Morrow) the 'coaching' provided by lecturers should involve the development of a respectful curiosity about the worldviews and epistemic values of their students. While ultimately the students need to do the running, the critical role that lecturers can play in their students' success - through actively facilitating epistemological access - should not be underestimated.

ACKNOWLEDGMENT

My thanks to my colleague, Dr Moyra Keane, for reading this paper and for her astute suggestions which have served to strengthen it.

PISA 2006 MAIN FINDINGS IN SLOVENIA AND SIMPSON'S PARADOX

Gašper Cankar

Educational Research Institute

gasper.cankar@guest.arnes.si

ABSTRACT

Programme for international student assessment (PISA) is a well known OECD global assessment of 15-year-olds in key subject areas that runs in three year cycles and its results usually gain high coverage by experts and media alike with main findings published in newspapers and other media. Author presents main findings of PISA 2006 study for Slovenia, where data shows the classic example of reversed effects often referred in statistical literature also as Simpson's paradox. This happens when results from groups suggest opposite conclusions than those made from results on combined groups. Seemingly easy question of »who performed better: boys or girls?« can have a very ambiguous answer.

Causes of paradox in specific case are explored and implications for interpretation of findings are discussed. Since it is likely that conditions leading to Simpson's paradox in context of Slovenian PISA 2006 results will remain constant in near future this finding should be kept in mind when the results from PISA 2009 will be available for interpretation at the end of 2010.

Keywords: *PISA, Simpson's paradox, gender differences.*

PISA 2006

There is growing awareness about importance of following achievement of students all over the world. International studies such as TIMSS and PISA provide plenty of high quality information on achievement and context to encourage focused research and meaningful interpretation. PISA 2006 included more than 400.000 students in 57 countries (OECD, 2007a) and provided plenty of interesting results for Slovenia with fairly good overall impression (Štraus, et al., 2007). However, even simple questions can have difficult answers.

SIMPSON'S PARADOX

Statisticians have long known that data can give ambiguous answers when approached differently. Specifically, the phenomenon where the probability of some event (i.e. that boys perform better than girls) increases in given population but decreases in every subpopulation is known as reversed effects or as Simpson's paradox (Kocik, 2001). It was first encountered by Karl Pearson in 1899 (Pearl, 1999) and later thoroughly explained by several authors (Blythe, 1972; Pearl, 1999).

One practical example from educational setting would be the 2006 US School study (Braun et al., 2006) where they compared public and private schools on their student performances. They reported findings that while math and reading levels were higher in private schools than in public schools, comparisons on demographic subgroups showed much smaller differences in both directions. Other examples can be found in various fields (Wagner, 1982).

Whenever Simpson's paradox occurs, it presents a challenge to the interpretation of results. If interpretation on one level opposes the interpretation of same results broken down by groups there should be an exploration into causes of such a shift and an increased attention when interpreting data.

RESULTS FOR BOYS AND GIRLS IN SLOVENIA

In this paper we explore PISA 2006 results for boys and girls. Gender differences are high on the list of main findings of educational studies and they are often reported, cited and used in setting educational policies. Table 1 shows performance of Slovenian students on PISA 2006 science achievement broken down by gender and different educational tracks. (Results were calculated from all five plausible values using SPSS Replicates module provided by ACER.)

Scores are reported on a common scale with 500 points as an OECD average. The educational tracks in table 1 are coded as: GIMg – 4-year general gymnasia, GIMs – 4-year technical gymnasia, STSI – 4-year technical education, SPI – 3-year vocational education and NPI – 2-year vocational education.

Table 1: PISA 2006 science achievement for Slovenia by educational track

Educ. track	Total	*S.E._total*	Girls	*S.E. Girls*	Boys	*S.E. Boys*	Diff.	*S.E. Diff.*
GIMg	599	1,9	590	2,2	614	3,9	**-25**	*4,7*
GIMs	544	2,4	528	4,0	560	3,5	**-32**	*5,7*
STSI	495	1,6	483	2,7	504	2,2	**-21**	*3,7*
SPI	421	1,9	406	3,0	429	2,5	**-23**	*3,9*
NPI	363	4,8	354	10,7	365	4,9	**-11**	*11,0*
TOTAL	523	*1,0*	526	*1,7*	519	*1,8*	**7**	*2,9*

*Note: One category was eliminated from original data, since it's not comparable (it depicts students still in primary education, while others are tracks of secondary education) and accounts for 3.7% of the population.

While boys outperform girls in every educational track, the girls outperform boys when results are combined, which is a clear case of Simpson's paradox. Explanation for the change can be tracked to different proportions of boys and girls in educational tracks as shown in Figure 1. When different tracks are combined the result for girls increases since most girls are in better performing tracks and result for boys decreases since boys prevail in lower performing tracks.

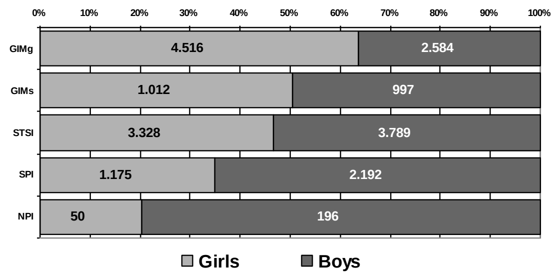

Figure 1: Proportions of boys and girls in different educational tracks as reported in PISA 2006 results for Slovenia. Numbers in bars represent size of the subpopulation.

To picture this relationship more clearly Simpson's paradox can be readily observed from Figures 2 and 3 where distributions of scores are plotted by gender for each educational track (Figure 2) and combined (Figure 3). Dots in each graph represent averages for subgroups of boys and girls.

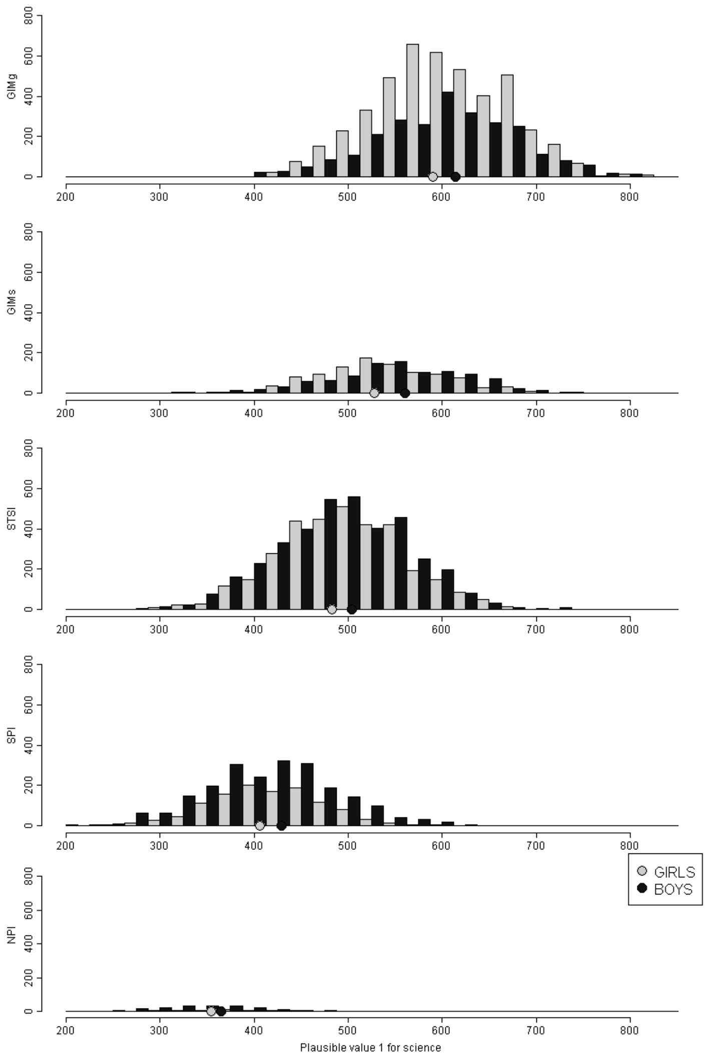

Figure 2: Distributions of PISA 2006 science scores in Slovenia by gender for each educational track.

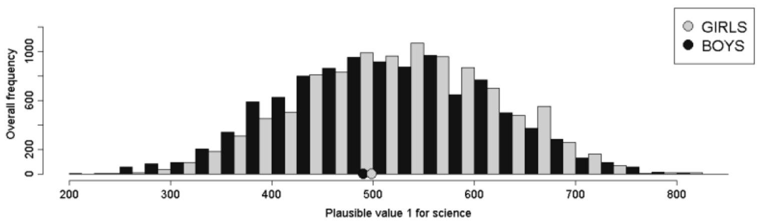

Figure 3: Distributions of PISA 2006 science scores in Slovenia by gender (overall results).

While boys outperform girls in every educational track overall results clearly show that this is more an effect of different gender proportions in different tracks than a real difference between gender subgroups. This can be verified by crosschecking the results from science achievement with those in the areas of reading and mathematics. Tables 2 and 3 show Slovenian PISA 2006 results for reading and mathematics respectively. In reading (Table 2) all the differences are in favour of girls and in mathematics all in favour of boys (Table 3). Nevertheless we can clearly observe the trend where aggregated results are always more favourable to girls than results by educational tracks are. Since the trends are similar regardless of the competency measured we can assume that causes behind such an effect are not specific to competency in science and can be indeed explained well with proportions of each group in specific educational track as shown in Figure 1.

Table 2: PISA 2006 reading achievement for Slovenia by educational track

Educ. track	Total	*S.E._total*	Girls	*S.E. Girls*	Boys	*S.E. Boys*	Diff.	*S.E. Diff.*
GIMg	566	1,6	574	1,9	553	3,1	**21**	3,7
GIMs	520	1,8	526	2,7	514	3,0	**12**	4,5
STSI	476	1,5	493	2,2	460	1,9	**33**	2,9
SPI	399	1,5	420	2,5	388	2,1	**31**	3,6
NPI	302	4,6	320	9,0	298	5,1	**23**	9,9
TOTAL	497	0,8	523	1,3	471	1,6	**52**	2,4

Table 3: PISA 2006 mathematics achievement for Slovenia by educational track

Educ. track	Total	*S.E._total*	Girls	*S.E. Girls*	Boys	*S.E. Boys*	Diff.	*S.E. Diff.*
GIMg	578	2,0	566	2,2	599	3,4	**-33**	3,9
GIMs	527	2,5	504	3,5	550	3,7	**-46**	5,3
STSI	480	1,5	461	2,5	497	2,3	**-36**	3,7
SPI	414	1,7	396	2,7	425	2,0	**-29**	3,2
NPI	392	4,2	363	10,5	399	4,5	**-36**	11,4
TOTAL	508	1,0	504	1,7	511	1,6	**-7**	2,7

RESULTS FROM OTHER COUNTRIES

Although findings have interesting implications for Slovenian results, we can further explore generalizability of findings by including results from other countries. We include PISA 2006 science results for five other central European countries that participated in PISA 2006 – Croatia, Czech Republic, Hungary, Slovak Republic and Austria. All results were again calculated from all five plausible values for science using SPSS Replicates. Since educational tracks in different countries are not directly comparable only mainstream tracks were used in analysis to account for at least 95% of the population covered in PISA 2006.

CROATIA

Mainstream educational tracks are in case of Croatia coded as follows: GYMN – 4-year gymnasium, VOC – 4-year vocational education, IND – 4-year industrial education, PROF – 3-year vocational and profession schools. Three additional subgroups were excluded from analysis because they were either not eligible or they covered very small proportion of the population. (Source: National PISA 2006 report obtained 10. 2. 2010 on http://www.pisa.hr/)

As Table 4 shows, results for Croatia also feature a case of Simpson’s paradox in gender differences although standard errors also allow different interpretation. Differences in specific educational tracks are nevertheless not followed on aggregate level and this can be described by proportions of girls and boys by educational tracks as shown in Figure 4.

Table 4: PISA 2006 science results for Croatia by educational track

Educ. track	Total	*S.E.*	Girls	*S.E. Girls*	Boys	*S.E. Boys*	Diff.	*S.E. Diff.*
GYMN	565	3,7	554	3,9	584	4,0	**-30**	*3,4*
VOC	493	3,4	479	4,0	507	4,0	**-28**	*4,7*
IND	421	6,6	410	6,8	429	9,6	**-19**	*11,7*
PROF	420	2,9	408	4,5	425	3,5	**-18**	*5,7*
Total	494	2,3	495	2,9	493	3,3	**2**	*4,1*

Note: Category of primary schools was excluded, since it is not a secondary education track. Categories of 4-year art education and lower vocational education were excluded since their large standard errors on total score lead to unstable differences. All excluded categories account for only 2.8% of the population.

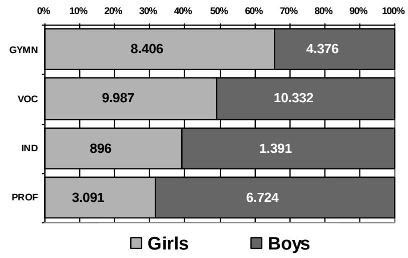

Figure 4: Proportions of boys and girls in different educational tracks as reported in PISA 2006 results for **Croatia**. Numbers in bars represent size of the subpopulation.

CZECH REPUBLIC

In Czech Republic educational tracks in Table 5 are coded as: GRAM – lower and upper secondary grammar schools, GYMN4 – 4-year gymnasiums, SOŠm – upper secondary technical or vocational schools that end with matura, SOŠ – other upper secondary vocational schools, ZAKL – compulsory schools that offer primary and lower secondary education.

Results in Table 5 are close to changing signs on aggregate level. The difference on aggregate level is again much more in favour of girls than on any specific educational track and Figure 5 shows familiar overrepresentation of girls in more demanding tracks as opposed to boys.

Table 5: PISA 2006 science results for Czech Republic by educational track

Educ. track	Total	*S.E.*	Girls	*S.E. Girls*	Boys	*S.E. Boys*	Diff.	*S.E. Diff.*
GRAM	628	6,4	617	6,6	642	7,0	**-25**	*4,4*
GYMN4	613	10,1	609	12,0	625	8,7	**-16**	*10,3*
SOŠm	542	5,7	525	6,8	556	7,9	**-31**	*10,6*
ZAKL	489	3,2	481	3,9	494	3,6	**-13**	*3,7*
SOŠ	443	*9,0*	413	*17,4*	453	*7,0*	**-40**	*16,0*
Total	518	*3,5*	516	*4,7*	520	*4,3*	**-3**	*5,6*

Note: Since in Czech Republic large proportion of 15-year old students is still in compulsory education, this category (ZAKL) remains in the analysis. Two categories were excluded since their large standard errors on total score lead to unstable differences. They account for 3.8% of the population.

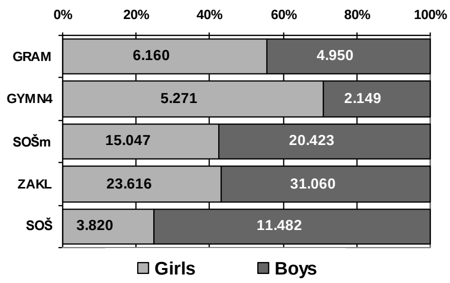

Figure 5: Proportions of boys and girls in different educational tracks as reported in PISA 2006 results for **Czech Republic**. Numbers in bars represent size of the subpopulation.

HUNGARY

In Hungary, Study Programme variable in PISA 2006 was coded to represent four different types of school: GYMN – 4-year grammar or gymnasium schools, VOC4 – 4- year vocational secondary schools, VOC3 – 3- year vocational schools and lower secondary schools. Last group was excluded from analysis, since it represents students, who are still in lower secondary education and didn't choose their educational track yet.

(information was obtained through personal communication with Ildikó Balázsi, NPM for PISA 2006 in Hungary.)

Results for Hungary in Table 6 are not a case of Simpson's paradox but it is clear that differences in each educational track are much greater than with results combined. Proportions of girls and boys in each educational track in Figure 6 again readily explain this effect with larger proportions of girls in more demanding tracks.

Table 6: PISA 2006 science results for Hungary by educational track

Educ. track	Total	*S.E.*	Girls	*S.E. Girls*	Boys	*S.E. Boys*	Diff.	*S.E. Diff.*
GYMN	561	4,6	550	4,1	576	7,1	-27	6,1
VOC4	507	3,5	492	4,7	522	3,8	-30	4,8
VOC3	431	4,0	419	4,7	437	4,4	-19	5,0
Total	513	2,6	507	3,4	519	3,4	-12	4,3

Note: Excluded group represents 7.7% of the total population.

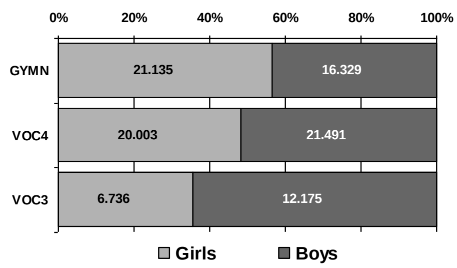

Figure 6: Proportions of boys and girls in different educational tracks as reported in PISA 2006 results for **Hungary**. Numbers in bars represent size of the subpopulation.

SLOVAK REPUBLIC

Codes, corresponding to educational tracks in Slovak Republic, are: GRAM – lower and upper secondary grammar schools, GYMN4 – 4-year gymnasiums, SOUm – upper secondary vocational schools that end with matura, SOU – upper secondary vocational schools, SOŠ – upper secondary vocational schools, ZAKL – compulsory schools that offer primary and lower secondary education.

Table 7: PISA 2006 science results for Slovak Republic by educational track

Educ. track	Total	*S.E.*	Girls	*S.E. Girls*	Boys	*S.E. Boys*	Diff.	*S.E. Diff.*
GRAM	592	7,9	584	9,8	601	8,0	**-17**	*9,6*
GYMN4	564	5,2	554	6,5	580	5,2	**-26**	*5,6*
SOŠ	502	*4,5*	488	*3,8*	521	*7,8*	**-33**	*7,5*
SOUm	473	12,0	449	9,8	483	12,7	**-34**	*11,1*
ZAKL	464	5,1	457	6,0	469	5,6	**-13**	*5,5*
SOU	416	*8,5*	407	*10,5*	420	*9,3*	**-13**	*9,7*
Total	490	*2,8*	487	*3,2*	494	*4,1*	**-7**	*4,6*

Note: Since in Slovak Republic large proportion of 15-year old students is still in compulsory education, this category (ZAKL) remains in the analysis. Two categories were excluded and they represent 1.7% of the total PISA population.

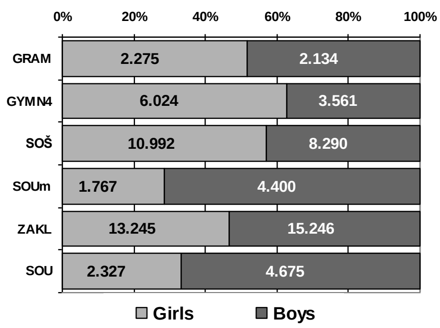

Figure 7: Proportions of boys and girls in different educational tracks as reported in PISA 2006 results for **Slovak Republic**. Numbers in bars represent size of the subpopulation.

AUSTRIA

Eleven different codes were used for Study Programme variable in Austria's PISA 2006 data. After inspection, only six indicated mainstream educational tracks as follows:

GYMN-Gymnasium Lower Secondary, HVOC-Higher vocational school, MVOC-Middle vocational school, APPR-Apprenticeship, POLY-Vocational Programme, HAUPT-Lower Secondary school (information was obtained through personal communication with Claudia Schreiner, NPM for PISA 2006 in Austria and Ursula Schwantner)

Austrian data in Table 8 shows only general dynamic of diminishing differences in aggregated data. Similary also the Figure 8 shows less explicit trend of increased proportion of girls in more academic tracks of education.

Table 8: PISA 2006 science results for Austria by educational track

Educ. track	Total	*S.E.*	Girls	*S.E. Girls*	Boys	*S.E. Boys*	Diff.	*S.E. Diff.*
GYMN	578	4,8	574	6,2	584	4,2	**-9**	5,7
HVOC	558	4,2	544	4,6	573	4,6	**-30**	5,0
MVOC	469	16,4	442	17,2	500	16,9	**-58**	20,5
APPR	460	5,2	435	6,7	472	5,2	**-37**	8,8
POLY	437	8,6	418	10,5	447	8,3	**-30**	6,5
HAUPT	404	13,4	386	19,7	414	12,7	**-28**	16,5
Total	512	4,1	508	5,5	516	4,2	**-9**	5,5

Note: Five codes were excluded for their small proportion of the population and large standard errors. They account for 4.3% of the population.

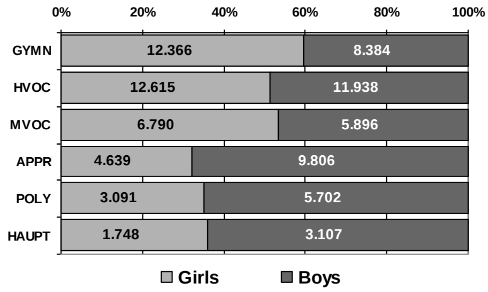

Figure 8: Proportions of boys and girls in different educational tracks as reported in PISA 2006 results for **Austria**. Numbers in bars represent size of the subpopulation.

CONCLUSION

Apart from purely academic interest in issue of Simpson’s paradox this research has also profound implications for practical use of PISA 2006 results by generalization of findings to other PISA cycles and international educational studies.

First reminder should always be that conclusions based upon results from subgroups don’t apply to the overall picture even when they all point in the same direction. Simpson’s paradox is not an obscure statistical peculiarity with low probability of occurrence. As demonstrated above reversed effects can be readily observed from real data and they do present a challenge to the adequate interpretation of results. In above results, unequal proportions of boys and girls that can lead to reversed effects were more or less present in all selected countries and should be strongly considered especially when interpreting results of such international studies by educational tracks.

Even more important is the other aspect of this research. There seems to be a systematic effect, observable in Slovenia and other countries included in the comparison, where boys and girls apply to different educational tracks in such a way as to maximize the differences in favour of boys in different tracks. Except in some usually small stratums of population in most cases it was clear that overall difference between boys and girls was more favourable to girls than results by educational tracks were. PISA 2006 results for Slovenia demonstrate this effect in science, reading and mathematics, although the change of signs that leads to Simpson’s paradox only surfaced in the science achievement. In other countries similar trends can be observed.

The trend stems from the fact that more girls than boys selected more demanding educational tracks. Since subgroup of boys in demanding tracks is smaller it is also more homogenous in it's relatively high achievement in those groups relative to the larger group of girls. In less demanding educational tracks the trend is reversed. Subgroup of girls is relatively smaller and relatively more homogenous in their (lower) achievement than their male peers in same track. This accentuates differences in each educational track in favour of boys compared to the overall differences and is a driving force behind observed Simpson's paradox.

This research lacks other perspectives like sociological, psychological or school policy evaluation that could give insight into dynamics creating observed differences between results on the level of whole country and results, broken down by educational tracks. Since this is a complex dynamic probably involving myriad of individual, sociological, societal, economic and other factors it remains a challenge for further research. However, this dynamic is being currently neglected in evaluation of gender differences in PISA, as done by OECD (2009) and could prove valuable if thoroughly researched. Databases of international educational studies seem more than appropriate starting point for such a task.

THE TIME IS RIGHT: EMBEDDING EDUCATION FOR SUSTAINABLE DEVELOPMENT INTO PRE-SERVICE SCIENCE AND TECHNOLOGY TEACHER EDUCATION

ABSTRACT

Against the background of the now urgent need for transitions to a sustainable future, this paper discusses pre-service education for sustainability (EfS/ ESD) within science education. Effective teacher education is a key enabler for EfS/ ESD and pre-service teachers require substantially more education in the area than they currently receive in most tertiary institutions. EfS/ESD is a complex, transformative and transdisciplinary field associated with particular pedagogies, content and processes and most effectively delivered through a whole-of-system approach. The Australian Sustainable Schools Initiative (AuSSI) provides a useful platform for considering pre-service EfS/ESD, tying in with EfS/ESD practice in an increasing number of Australian schools. This paper argues for pre-service teacher education for sustainability within science education and reports on a formal evaluation of embedding five AuSSI modules into the semester long second-year unit EDST 204 Science & Technology for Primary Teachers 2 within the Bachelor of Education degree for primary (elementary) pre-service teachers at the Australian Catholic University in Melbourne. The findings of this evaluation speak to the implementation of EfS/ESD more broadly within pre-service teacher education.

Keywords: *Pre-service teacher education, education for sustainability, the Australian Sustainable Schools Initiative (AuSSI)*

INTRODUCTION

Recent years have seen an increasing acceptance of the ecologically fragile state of our world with its vast human load beginning to exceed carrying capacity. The issues of environmental sustainability have been identified in significant international reports and meetings including the 1992 United Nations Conference on Environment and Development that produced the blueprint for the global implementation of sustainable development - *Agenda 21,* and the 2000 United Nations General Assembly's *Millennium Declaration.* More recently, we have seen the highly influential Intergovernmental Panel on Climate Change **(**IPCC**)** *Climate Change 2007*, the *Stern Review on the Economics of Climate Change* (2007), while not forgetting Al Gore's *The Inconvenient Truth* and the disappointing if iconic 2009 United Nations Climate Conference in Copenhagen. Already published this year is the Worldwatch Institute's *State of the World* report (Assadourian & Yunus, 2010). Together these documents and meetings argue that hyper-consumption levels fuelled by carbon-based energy have fundamentally altered the planetary conditions for life. They also argue that profound changes to humanity's collective cultural values are required if we are to reshape our relationships with the natural systems of which we are part and upon which we depend.

It is now also widely accepted that education is one of the most effective means we have of bringing about such cultural change needed for the transition to sustainability. Indeed, the highly significant *Agenda 21* emphasized the role of education in the move towards an environmentally sustainable future:

> Education is critical for promoting sustainable development and improving the capacity of the people to address environment and development issues (Chapter 36, Para 36.3).

Adopting a similar perspective, the United Nations General Assembly declared the years 2005 to 2014 to be the Decade of Education for Sustainable Development (UN DESD), inviting participation from governments worldwide. Within in our context, Australia was well placed to respond with the release of the first *National Action Plan for Education for Sustainable Development* (NAP) in 2000, and the subsequent establishment of the *National Environmental Education Council (NEEC)* that commissioned a review of nationwide curriculum documents and identified national priorities. Pilot sustainable schools programs in New South Wales and Victoria were implemented as a result. *Educating for a Sustainable Future – A National Environmental Education Statement for Australian Schools (NEES)* followed in 2005, and provided a nationally agreed vision and implementation framework of the nature and purpose of environmental education for sustainability through all years of schooling. Positive evaluation of pilot sustainable schools programs lead to the development of the Australian Sustainable Schools Initiative (AuSSI) gradually spreading throughout the all states by 2008. *Caring for Our Future -The Australian Government Strategy for the UNDESD* bought together a number of these schemes and foreshadowed the development of the second NAP, *Living Sustainably: the Australian Government's National Action Plan for Education for Sustainability* released in 2009.These and other policy initiatives by the Australian Government have recently been cited as amongst world’s best practice in the report *Climate Change and Sustainable development: The Response from Education* released in 2009 (Læssøe, Schnack, Breting & Rolls, 2009).

Given that what is at stake in environmental degradation are climate change, desertification and destruction of agricultural land, the depletion of forests, loss of biodiversity and species habitat, and the pollution of the atmosphere, waterways and oceans, science education seems a natural space for education about and for environmental sustainability (EfS). In an excellent overview, Gough (2008) describes the lengthy relationship between science education and environmental education, arguing in essence, that their relationship has strengthened with the growing recognition of the necessity of environmental sustainability. Gough (2008) quotes Jenkins and Pell (2006) to conclude that since many environmental problems (and their solutions) are science related, then there is clearly a role for school science education, and goes onto argue that:

> (b)y bringing science education and environmental education together in the school curriculum, science content is appropriate to a wider range of students and more culturally and socially relevant. The convergence is also important for environmental education, because it needs science education to underpin the achievement of its objectives and to provide it with a legitimate space in the curriculum to meet its goals (p.41).

Moreover, she believes that EfS should be part of any approach to science education that attempts to address the decline of students’ interest in school science apparent from many studies by those like Dekkers and de Laeter (2001), and perhaps most significantly, the extensive Relevance of Science Education (ROSE) Project (Schreiner & Sjøberg, 2004). Indeed, the recent addition of a strand of interest - Strand 14 Environmental Education- within the world’s largest science education research organisation, the United States based National Association for Research in Science Teaching (NARST) would seem to support a belief in the mutualism (Gough’s 2000 term) between science and environmental education.

As many science teachers, and particularly primary (elementary) science teachers, do not possess a viable knowledge and background in environmental education, it is not surprising that EfS or education for sustainable development (ESD) is currently absent from much school science curricula. Effective future pre-service teacher education will be a key enabler for the development and implementation of appropriate EfS/ESD. Hence, this paper argues for pre-service teacher education for sustainability within primary science education as a natural place for EfS/ESD, and outlines the Australian Sustainable Schools Initiative (AuSSI) as a new generation program that can provide a useful framework for pre-service teacher EfS/ESD. In addition, it reports on a formal evaluation of embedding five AuSSI modules into the semester long second-year unit *EDST 204 Science & Technology for Primary Teachers 2* within the Bachelor of Education degree for primary (elementary) pre-service teachers at the Australian Catholic University in Melbourne. The findings of this evaluation speak to the implementation of EfS/ESD more broadly within pre-service teacher education. We begin this discussion then, with a brief review of the shift in perspective from environmental education to EfS/ESD.

THE MOVE FROM ENVIRONMENTAL EDUCATION FOR SUSTAINABILITY AND EDUCATION TO EDUCATION FOR SUSTAINABLE DEVELOPMENT (EFS/ESD)

Environmental education as a separate field had its origins in the ecological degradation identified by Rachel Carson in her 1962 book *Silent Spring* (Gough, 2008). Throughout the 1970's, culminating in the 1977 landmark Tblisi declaration that called for formalized environmental education for the first time, early environmental educators emphasized a scientific knowledge base focussed on natural subsystems (Tilbury, 1995). Nature-society interactions were usually reduced to a series of inputs or outcomes (Reid & Scott, 2006). Over time, and as the inadequacy of this somewhat one-dimensional approach became apparent, there was a substantial shift towards the promotion of sustainability and sustainable development (Gallopin, 2002). Initially endorsed by the World Conservation Strategy in 1980 and later by the 1987 Brundtland Report, education for sustainability called for the development of a conservation mindset within environmentally sound values as well as understanding the sustainable use of natural resources. Bonnet (2002) tell us that it was based on the three requirements of the maintenance of life-support systems, the preservation of genetic diversity (extending to species and habitat diversity), and the sustainable use of natural resources. At the same time as calling for people's increased participation in the conservation and management of their own environments, education for sustainability proactively aimed to prevent problems arising rather than cleaning up the mess afterwards.

Firmly embraced by the 1992 United Nations Conference on Environment and Development - *Agenda 21*, this newer approach placed humans into the system, recognising the roles played by historical, socio-cultural and economic-political assemblages on underlying worldviews and power structures. EfS/ESD problematises and exposes these interrelationships that shape global, national and local responses to issues around sustainability, including multicultural and indigenous perspectives. Indeed, the Australian Government's 2009 NAP- *Living Sustainably* argues that

> "the focus has shifted from knowledge of the natural ecosystems and threats posed to them by overuse and deletion of resources to equipping all people with the knowledge skills and understanding necessary to make decisions based upon full environmental, social and economic implications" (p.10).

There is much agreement that EfS/ESD is a promising development but its sheer complexity encompassing as it does the integration of so many areas of human endeavour, perhaps not surprisingly, invites significant conflict. For example, it raises issues about whether EfS/ESD' central purpose is primarily educational or more broadly social, reflecting the greater tension between environmental protection and development and social justice arguments. Moreover, sustainability itself is a term with multiple meanings and descriptions, anywhere from ecocentric attempts to move away from economic growth, to those which argue that it disguises what is to be sustained, namely a Western affluent lifestyle (Smyth, 2005). Indeed as Gough (2008) points out, while the broader sustainability agenda around the social and economic includes health, poverty and redistributive justice agendas, in the developed world, EfS/ESD tends to remain focussed on the natural environment despite attempts by those like Reid, Bjarne Bruun, Nikel and Simovska, (2008) and Smith (2009) to incorporate these broader agendas.

While the 2009 report *Climate Change and Sustainable development: The Response from Education* devotes a full chapter to the divergent interpretations and meanings of EfS/ESD, it is suffice here to make a number of general observations about characteristics of EfS/ESD within our context. These include that EfS/ESD:

- is concerned with how people interact with their total environment and with addressing environmental problems holistically through the curriculum. Hence, holism is its philosophical basis.
- employs 'synthesis' as a methodological approach which assumes that studying interdependence and interactions leads to the emergence of new properties.
- investigates the environment at different environmental scales. This means investigations of different local, regional, national and global environmental problems and an exploration of the their links.
- recognises that engagement in environmental improvement extends beyond the cognitive to a individual sense of responsibility generated by a personal environmental ethic. Thus, central to the success of EfS/ESD is the promotion of an environmental ethic which has sustainable living at its core. This includes developing an understanding of place and a deepening connection to nature.
- tends to involve issue-based learning through relevant concepts, values and morality: (i) identifying issues; (ii) investigating issues; (iii) seeking solutions to issues; (iv) carrying out actions to address issues; and (v) evaluating the impact of the environmental actions taken to resolve these issues. It is not merely about discussing solutions to enhance awareness; rather it is purposeful and active exploration of issues, and the identification and enaction of potential solutions.

Clearly, if schools are to be proactive in implementing EfS/ESD of this type either within their science programmes or elsewhere, then EfS/ESD needs to become a core element in both in-service and pre-service teacher education. Indeed, the 2004 evaluation mentioned above of the Victorian pilot sustainability schools project developed by the Centre for Education and Research in Environmental Strategies (CERES) and the Gould League, made 16 recommendations for forwarding the EfS/ESD agenda in that Australian state. Recommendation 10 identified the importance of ‘ongoing professional development and pre-service training in environmental education for teachers in Victoria’ (Larri, 2004 p.12).

PRE-SERVICE TEACHER EDUCATION

In addition to the other policy and programme initiatives already described, in 2003 the Australian Government established the Australian Research Institute in Education for Sustainability (ARIES) at Macquarie University. ARIES conducted a general review of environmental education/EfS/ESD in Australia across all sectors including pockets of good practice in pre-service teacher education, in an attempt to identify opportunities, incentives and constraints that could impinge upon the mainstreaming of EfS/ESD (Ferreira, Ryan & Tilbury, 2006). The ARIES report evaluated models of pre-service EfS practice including (1) the collaborative resource development and adaptation model, a largely one-off program approach; (2) the action research model, and (3) the whole-of-system model. Ferreira et al. (2006) found that core features of the action research model, when combined with the whole-of-system model, provided the best combination for successful mainstreaming of EfS/ESD. The whole-of-system model is a complex layering and networking of all elements within the pre-service teacher education context so that the organisational culture, programs and courses, personnel, and procedures and processes work in tandem to bring about change. The authors went on to argue that when combined with action research methodology, the whole-of-system model provides a powerful means for developing practitioners' sense of ownership, autonomy, and ability to bring about change within their own particular setting.

While the ARIES report considers the whole-of-system to be ideal, it is clearly complex and difficult to achieve. Issues of co-ordination, having sufficient committed staff and the need for high level support and resources, means it is not always possible to implement or mainstream on a large scale. Indeed, there is an argument for small scale change as part of a larger strategy of capacity building and longer term, more sustaining, attitudinal and behavioural change. Critical factors for success within pre-service teacher education include the development of a curriculum focus and pedagogical strategies reflective of EfS/ESD principles like those described above such as a holism, environmental ethics, issues-based learning, critical and reflective processes, a transdisciplinary approach, and transformational pedagogies. As well, broadly-based partnerships and networks between teacher preparation institutions and a variety of sectors such as Non Government Organisations (NGOs), inter-governmental bodies, resource centres, and industry bodies, enable a deeper engagement by participants in a diversity of settings, which more likely embeds a long-term commitment to EfS/ESD.

The resultant sustainability-literate teacher graduate would be expected to understand the importance of sustainability, be competent in relevant pedagogies and curricula, have a commitment to social justice and equity, and seek to adopt socially transformative agenda. They would be ecoliterate, which includes an understanding of the dimensions and systems nature of sustainability, an understanding of ecology and planetary biosystems and their limits, empathy and connection with nature (biophilia) (Kellert & Wilson, 1993), knowledge of the role of economics and politics, and empowerment to play a leading role in their creation sustainable societies; a tall order indeed!

THE AUSTRALIAN SUSTAINABLE SCHOOLS INITIATIVE

The above approach to pre-service teacher education fits within the umbrella strategy for implementing EfS/ESD with Australian schools – the Australian Sustainable Schools Initiative (AuSSI). Developed initially in 2004, in general terms AuSSI is one of the new generation of environmental programs that takes schools beyond mere awareness raising to strategy planning, and on to action and, in many cases, environmental leadership. It provides a framework for widespread cultural and organisational change and is introduced as a flexible professional development program for teachers, pre-service teachers, administration staff, parents and other interested groups. The process builds on existing achievements and encourages the involvement of the whole school's local community in shifting towards more sustainable practices and processes. It seeks to develop relationships with other areas that impact on the organisation and management of a school such as NGOs, and resource centres, and assists schools to achieve real-world and measurable social, environmental, educational and financial outcomes.

Each Australian state has its own version of the AuSSI reflecting the diverse historical lines of state-based EfS/ESD. In Victoria for example, AuSSI (Vic) provides a customised program of five modules. They comprise a core module focussing on general issues of the sustainable school, culminating in the development of a customised, holistic school environment management plan that establishes baselines and set targets. The other four are energy (energy conservation, renewable energy, air quality and reduction in greenhouse gas emissions); water (water use, water conservation and storm water management); waste

(waste/litter minimisation and recycling) and biodiversity, (monitoring and developing indigenous and food gardens).

EVALUATING AuSSI (Vic) WITHIN PRE-SERVICE TEACHER EDUCATION

In this section, the evaluation findings of embedding the five AuSSI (Vic) modules into the semester long second-year unit *EDST 204 Science & Technology for Primary Teachers 2* within the Bachelor of Education degree for primary pre-service teachers at the Australian Catholic University in Melbourne are summarised. The evaluation aimed to establish the efficacy with which elements of AuSSI (Vic) as an example of pre-service teacher EfS/ESD has contributed to students' learning. The unit covered 12 weeks' teaching delivered in a weekly one-hour lecture and two-hour tutorial during 2008 (July-October). The lectures introduced and delivered the rationale and key knowledge-base concepts underpinning the five AuSSI (Vic) modules: core module, water, waste, energy, biodiversity. The tutorials provided a small group setting for students to reflect on and discuss the issues from the lectures and to research and present their learning. As the total number of teaching time was 36 hours, not all characteristics of EfS/ESD described in the section above were able to be incorporated into the unit and are hence, not reported on here. Moreover, the unit was not designed to provide substantial curriculum and pedagogical knowledge.

The evaluation consisted of an interpretation of a random sample of students' responses to a baseline survey conducted on-line before undertaking EDST 204, and a post- unit survey at the end. Approximately one-third of the students were included in the sample (N= 33), and the same students were surveyed both times. The post-survey questions included those asked in the pre-survey as well as additional questions specific to the unit. The questions sought information about the students' knowledge base, attitudes and behaviours pertinent to sustainability in general and the AuSSI (Vic) modules in particular. Student responses to questions evaluating their knowledge base are reported below under headings corresponding with the AuSSI (Vic) modules.

KNOWLEDGE BASE

Energy

When asked to give four ways to reduce energy consumption in the home or school, the students showed a strong consistency between their pre- and post-tests, indicating an already significant level of prior learning in this area. This learning could have come variously from their previous school knowledge and the types of solutions heavily promoted by the media. One difference was that in the pre-test, the students did not always discriminate between energy conservation and other types of conservation, citing using grey water, installing a water tank and composting as examples of energy conservation. This understanding improved in the post-test. More significantly though, when asked to explain the connection between energy generation and use and climate change, the pre-test responses were vague, and while the post-test responses were generally better, this appears to be an area that needs further work. A general confusion about the links between climate change, greenhouse gases and the ozone hole was identified. Typical students' comments were:

Pre-test: *S2-The more we use energy the more fuels and gases are released into our environment this leads to climate change.*

Post-test: *S2-The majority of countries burn fossil fuels to generate energy as electricity. The CO_2 emissions from humans using such energy have increased into the atmosphere. Through the greenhouse effect, the atmosphere becomes choked with gases and the sun's heat cannot escape this haze thus increasing temperatures on earth. This ultimately means, reducing rainfall, increasing hostile storm fronts, melting snowcaps. Deforestation has contributed greatly to the climate change.*

Without the trees to photosynthesise, our air is not as clean and there are fewer trees to do more work to keep us alive

Water

In this section the students were asked about their understanding of the water cycle, water consumption in the home and ways to reduce it. In terms of water use and conservation again there was a strong consistency in the pre- and post-test responses, reflecting a good prior knowledge. While clearly all students had previously formally learnt about the water cycle, their post-test responses indicated a deeper understanding with more recourse to technical language.

Pre-test: *S3 - The movement of water through the following stages:1. evaporation 2. transpiration 3. condensation 4. precipitation 5. Storage*

Post-test: *S3- Clouds are formed over the oceans through condensation. Water particles become heavier, move across land and produces precipitation. Rain falls on land, trees, lakes, mountains (as snow, ice). Water is absorbed by the land, some is used by the trees. Transpiration occurs through the trees photosynthesizing. Evaporation from bodies of water, condensation into clouds again*.

Waste

Here, students were asked about their knowledge of landfill and the importance of composting. The students' knowledge clearly improved as a consequence of the unit, as the pre-test indicated that the level of prior knowledge was relatively low. For example, they had a much greater understanding of the composition and importance of the role of compost in soil health as indicated by the following quotes.

Pre-test: *S4- It is good for the soil. Puts nutrients into the soil. Recycles food scraps.*

Post-test: *S4 - Composting provides an almost constant source of free fertilizer and soil conditioner. The organic materials in the compost help your plants grow by loosening the soil and allowing better root entry. The texture of compost improves the solid ability to hold water and can reduce your water bills. Compost has all the nutrients that plants require, unlike chemical fertilizers. Through regular use of compost you can greatly reduce or even get rid of the need for chemical fertilizers, pesticides and herbicides, which saves money and reduces contamination of our waterways and drinking water.*

Further, the students' knowledge of what went into landfill and why this is problematic increased after studying the unit. This increase in learning can almost certainly be attributed to the unit since it reflects knowledge and understanding not generally promoted in the media and elsewhere. Hence, science and related concepts around waste need to be specifically taught.

Biodiversity

This was a concept that the pre-test data showed as having the lowest level of understanding, and students' understanding of biodiversity improved significantly as a consequence of studying this unit. Not only were they able to identify biodiversity as a major environmental issue in the post-test compared with the pre-test, but they were able to explain and expand on its meaning to include genetic and ecosystem diversity.

Pre-test: *S5- This includes many different things which contribute to our world and maintain its natural flow or existence.*

Post-test: -*S5: Biodiversity is the variety of all living things; the different plants, animals and micro organisms, the genetic information they contain and the ecosystems they form. As a developed nation, Australia has a special responsibility for biodiversity conservation and management.*

The students were also asked to explain what they understood by the terms *food web, habitat* and *ecosystem.* As these concepts are studied at secondary school, it was expected that their prior learning would be evident in the pre-test. While this was the case, the unit contributed to more sophisticated understanding particularly in the students' accurate use of technical terms.

ATTITUDES TO SUSTAINABILITY AND EFS/ESD

Even though 100% of students reported a very positive attitude towards issues of sustainability at the beginning of the unit, and believed they needed to take personal responsibility for their attitudes and actions, they found the unit contributed to raising their consciousness and empowering them towards action. The post questionnaire showed that more students were able to identify and articulate reasons for their attitude, indicating an increased knowledge base and understanding of their own position I terms of values and feelings. This probably reflects the presentations and discussions that took place in depth in the tutorials.

Pre-test: *S6 - Of course, we are all a part of the environment around us, and if we do not care for it ourselves who will?*
Post-test: *S6: Yes, before undertaking this unit I cared about the environment but didn't really know what actions I could take to make a difference I now understand that there is a lot which can be done on a person level.*

A new element at the end of the unit was the significant number (25%) who indicated that the unit had helped them realise the importance of EfS/ESD and had given them a strong basis for educating children. They realise that they will need to be role models for their own students.

Post–test: *S1- My attitude has changed. This unit has made me more conscious of my actions and the impact they have on the environment. Also, I have recognised the importance of this issue and how we, as teachers, can teach students how to live sustainably.*

S2: I do feel a sense of responsibility, especially since I am going to become a teacher, where students I will be seen as a role model. I also believe that while the environment provides for us, we should provide for the environment. Therefore, our effect on the environment, will effect the lifestyle of future generations, so we need to act responsibly in order to ensure an adequate lifestyle for the future."

S3: I was aware of the importance of sustainability before completing this unit. but I have been able to gain further knowledge and build my understandings further which will help me become a successful teacher of sustainability.

The students appeared to have obtained their attitudes from the media, their parents and previous education. A few noted experiential or spiritual reasons. It is highly likely that for many students learning about sustainability is largely cognitive/rational rather than a deeply held experiential or even spiritual connection (ie it doesn't necessarily 'touch' everyone). This probably accords with Gardner's multiple intelligences, where only around 10% of students are considered to have a high naturalistic/experiential intelligence. This has implications for a multi-dimensional approach to EfS/ESD.

Post–test: *S5: We all contribute to and have a huge impact on the world. Only recently has it concerned me, as we are beginning to see exactly what it is doing and will continue to do. I first learnt in more depth about this last year and have continued to follow it through the news and documentaries.*

BEHAVIOURS

The post-test shows a shift towards a clearer articulation of actual concrete behaviours around reduction of consumption and towards a conserver lifestyle. By the end of the unit the students had access to a wider range of options for working towards sustainability. There was also a clear articulation of being conscious and aware of personal impact of the importance of taking personal responsibility, and again there was an increase in the emphasis on education.

Post–test: *S1: We all need to become more conscious and aware of the consequences of our actions/think before acting think about things in our lives that impact the size of our ecological footprint*
S2: Inform and educate others on what they can do.

S3: We need to initiate effective strategies to live by, in order to maintain a sustainable environment. Change the way we live.

To gauge behaviour, students were asked the extent to which they participated in particular pro-sustainability behaviours relating to the 5 AuSSI (Vic) modules. For each item students were required to answer either *mostly, sometimes* or *never.* T-testing was applied to gauge any difference in responses between the beginning and end of the unit.

Responses are graphed below, showing students' engagement in particular behaviours before and after the unit. Overall there was a slight but not statistically significant difference in the behaviours.

SUMMARY OF THE FINDINGS

Overall, it was apparent from the post-test data that the unit contributed to students' knowledge about AuSSI (Vic) as well as positive attitudes towards, and appropriate behaviours around, sustainability on all the assessed aspects. However, the pre-test data indicated that students' prior learning in some aspects of sustainability was already significant. Specifically, a greater depth in answering the questions, the correct use of scientific and technical language and more nuanced and clearly articulated comments reflected a better level of understanding of sustainability concepts after completion of *EDST 204.* All students reported that they had gained much from and enjoyed the unit.

Post–test: S2 - What a great unit. What can we all learn from this unit. Firstly it addressed a real need, a need to do something, a need to educate future generations. It was fun and personally challenging. Most people seem to have no interest in anything to do with sustainability. The answer is to educate them and design projects that make them aware It is up to us as educators of the future to spread the danger and urgency of our need to save the planet. Our personal consumer choices have ecological, social, and spiritual consequences. It is time to re-examine some of our deeply held notions that underline our lives; my attitude towards sustainability has become stronger and I am more prepared to speak out and encourage others to do their but for our planet.

There was also a significant increase in the number of students who felt they could influence children as a teacher which is evidence of the emergence of students' identities as teachers of EfS/ESD.

Post–test: *S5: I thought this unit was very helpful in the teaching career as it is important to teach children about the very issues that are around us*

CONCLUSION

The preliminary evaluation of the unit *EDST204* has convinced us of the importance of a dedicated unit for EfS/ESD, an enabled us to 'fine tune' the curricula and pedagogical strategies. For example, we now know to that as there is considerable level of student prior learning in sustainability, the unit should be taught at a more rigorous level. This means a greater emphasis on content with an increased level of conceptual understanding and technical knowledge, particularly in the most poorly understood concepts of energy, climate change and the ozone hole. Moreover, we could cater better for preferred learning styles and include more issues-based options within the tasks.

It is early days for pre-service teacher education in EfS/ESD. Most Australian teacher preparation courses at primary level include some EfS/ESD but usually as an optional elective taken by students to complete the credit points requirement. Thus there are very few pre-service teachers being skilled in the background necessary to become effective and committed teachers of EfS/ESD. The Australian Catholic University is an exception as EfS/ESD is now a core unit meaning that all primary teaching graduates have the opportunity to engage with the field. That said though, and in tandem with the 2009 report *Climate Change and Sustainable development: The Response from Education,* much more research is required into EfS/ESD pre-service teacher education

ASSESSMENT FOR LEARNING IN INQUIRY BASED SCIENCE EDUCATION: from an individualistic to A Socio-cultural view

Cristina Carulla

Aalborg University

ccarulla@learning.aau.dk

ABSTRACT

Inquiry Based Science Education praxis is growing in different cultures, social environments and continents. Assessment for learning, whose purpose is to help students through their learning process, has been used as part of inquiry teaching strategies. Assessment judgments are based on the learning evidences of each student and interpreted from a constructivist model where conceptual change and mental representations are explored. During the inquiry lessons, the students learn in groups by developing inquiry thinking when they explore phenomena. The teacher helps students supporting their own inquiry process assessing their answers and activities. The interpretations of learning process from a constructivist learning view do not take into account the impact of the socio-cultural context on learning processes. The current focus of assessment is on the outcomes, achievements and learning processes in the individual mind, and less attention is given to the learning processes during the interactions between the students and the teacher. Thus, adopting socio-cultural learning theories can contribute with a new perspective in IBSE for this assessment process, in which the learning evidence is focused on students' interactions and activities rather than on individual outcomes. In this way, the effect of the socio-cultural context on the learning process can be taken into consideration.

Keywords: *Inquiry Based Science Education, assessment for learning, constructivism, conceptual change, socio-cultural theories, interactions, learning evidences.*

INTRODUCTION

My research takes place in the field of assessment for learning in Inquiry-Based Science Education (IBSE). Inquiry Based Science Education can be seen as "particular way" to teach scientific knowledge and to learn scientific reasoning and contents. This "particular way" is characterized by the fact that "the learners are making sense of new experiences for (not by) themselves, being active in constructing knowledge through their mental and physical activity (not passive receivers), linking new experiences to past ones, testing ideas and reconstructing their own ideas and using ideas from others" (Harlen, 2007). In addition, teachers set activities that encourage that kind of learning experiences, by bringing the learners in contact with physical phenomena, materials, texts, and allowing them to communicate their own ideas and participate in discussions (Harlen, 2007). At the same time, IBSE can be seen as a growing network in different cultures, social environments and continents (e.g. http://www.pollen-europa.net, http://lamap.inrp.fr, http://www.indagala.org/), supported on learning sequences that have been constructed by different experts and practitioners in different countries, bearing in mind that "particular way" of seeing learning and teaching.

On these grounds, a specific view of assessment has emerged, and it has been presented and used by different IBSE researchers, teacher educators, and teachers in different cultural environments. This movement is based on the concept of *assessment for learning*, whose purpose is to help students to learn (Black & Wiliam, 1998). Assessment for learning has become particularly meaningful for IBSE (e.g. www.exploratorium.edu/ifi/workshops, http://www.pollen-europa.net). Assessment for learning in IBSE has been promoted as part of the teaching strategy in order to support students' inquiry experiences in all the typical phases of a learning process. In that sense, the teacher needs to inquire, for instance, if a student knows how to ask questions that are researchable, how to draw evidence-based conclusions, or how to plan and investigate in order to collect evidence and make explanations. Assessment is a tool that the teacher uses to find out how students are doing in each phase, and to help them make progress in their own reconstruction of ideas (Black & Wiliam, 1998). To help the students to learn, the teacher needs to gather information on the way students think, make interpretations about the thinking process, determine how far their knowledge is from the expected learning goals, and adjust teaching activities to secure progress in students' thinking (Harlen, 2006a; Ruiz-Primo & Furtak, 2006).

THE TENSIONS

One of the strong foundations of the IBSE praxis is that during the activities in the classroom, students make their research, discuss and communicate their own ideas and arguments in small groups. The learners work together in order to agree on questions and problems that they want to answer, and use materials, books, Internet or other resources to draw conclusions and explanations related to particular phenomena (Saltiel, 2006). After that, they communicate their ideas to others -–including the teacher– and they discuss them and come to an agreement on what is acceptable for everyone.

According to the main statements of assessment for learning in IBSE, teachers must have information about every learner's process during the different phases and different activities (by themselves, in groups, in classroom discussions) (Ruiz-Primo, Li, Tsai, & Schneider, 2007; Shavelson, et al., 2008). The kind of information needed for the assessment process is that which, in some way, can open a door that gives the teacher access to the learning process taking place inside the learner: "To know how students are doing, teachers need a way to 'get into students' heads' and understand how they're thinking […] assessment will be used to see how students understand science concepts, and how effectively they are using the science process skills" (Harlen, 2006b, 10). The purpose of this kind of assessment is to help the learning process that is happening in every student's head.

However, it is not clear that the communication and interactions around particular problems when the students work together necessarily help every student to learn what teachers expect. At the same time, it is difficult to know about the quality of the processes happening when the students are interacting in groups. The quality of the process depends on the previous knowledge and the language they can use to describe and analyze the facts they are observing in relation to their ideas. Many different factors have been reported as having impact on that quality. For example, (Mercer, Dawes, & Wegerif, 2004) in their research about group work, argue that a "possible explanation for the doubtful quality of much collaborative talk is that children do not bring to this task a clear conception of what they are expected to do, or what would constitute a good, effective discussion". Their interpretation of this statement is that "many children may rarely encounter examples of such discussion in their lives out of school –and teachers rarely encounter their own expectations or criteria for effective discussion explicit to children" (p.361).

Taking into account those facts, I will explore how assessment for learning can be conceptualized from a theoretical perspective that includes the learning process occurring during the group work and in the collective discussions. Certainly when students are working in groups, without the teacher being present, a learning process is going on during their interactions. The teacher has no access to that process and neither to the learning process happening in the students' "heads". The problem of having or not direct access to the individual learning process has been part of the development of assessment research, and there have been many assumptions about the way to access or open that door to the learning process of individuals. Furthermore, different theoretical tools have been developed in order to interpret the learning process happening inside the learners' heads, based on the "learning evidence". Nevertheless, I have not found theoretical assessment tools that take into account the collective learning and thinking processes that take place in different interactional moments.

Therefore, I propose to move from a view of assessment for learning focused on the individual learning development, to one that considers the role of the others in the learning process. For that, I will explore learning theories that support the assumptions and interpretations of learning evidence, and at the same time, conduct the different assessment activities that have been claimed as relevant to help every student to learn in the IBSE assessment research. I will argue that although the relevance of the others for the individual learning process is recognized, the assessment activities have not focused on the role of the others in the individual learning process. I will try to recover the role of others in the assessment activities by focusing the view on the learning process happening during different kinds of interactions. Based on a short IBSE classroom story, I will show the way in which IBSE assessment for learning can work when constructivism-learning theory is adopted, and the particular way to see the contribution of the others to the learning process. After that, I will present another possibility that can be adopted in the IBSE assessment for learning perspective. I will introduce some elements of socio-cultural learning theories that will take part on the assessment, focusing on the collective thinking and learning moments in IBSE classrooms.

DIVERSITY OF MOMENTS IN IBSE CLASSROOMS

In order to substantiate my claims presented above, I will compile fragments of IBSE classroom sessions from experiences shared by teachers, presented in research reports, shown in IBSE videos, and my own teaching. I will organize the fragments in a story that will illustrate certain typical moments in IBSE classrooms. The story will guide my reflections and illustrate the contrast of theoretical perspectives in assessment for learning. I will give each moment the name of a particular space in which different talking, activities, objects, resources and people's expressions interact at the same time, so that each one will give meaning to the whole situation.

In a particular state school in Bogota, before going to the classroom, Blanca, a 4th grade science teacher told me that during the activity that I was about to visit, she would assess the learners' ideas in order to plan the teaching sequences for teaching the students about buoyancy. She told me that at the beginning of the learning sequence, many learners think that the mass of the objects influences the buoyancy (see examples of diversity of stages on understanding about buoyancy of the objects in Furtack & Ruiz-Primo (2007)). She told me that she would collect their ideas at this moment and try to evaluate their capacity to make predictions and hypothesis.

I call **Teacher Own Space –TOS–** the moments in which the teachers prepares the teaching by themselves, as well as those in which they think and act during the class without interacting with others: they talk to themselves and make decisions about materials, activities and uses of time by their own. In the story, for example, Blanca brings to the classroom 11 aquaria, 11 sealed containers with something inside (Object A), 11 sealed smaller and thinner containers than the first ones (Object B), filled with the same material as the former containers. She organizes the materials on the front table. Then, she sticks a big poster on the wall. The poster has a table with three columns. There are drawings of the objects in the first column. There is a label that says "*what will happen"* in the second one. And there is a third column headed with the question "*why does the group think it will be floating or sinking?"* At the same time, she puts 41 copies with questions on the table.

By **Collective Space –CS–** I mean the moments when the teacher and the children are sharing ideas all together: talking about something they are looking at, writing on the board, or answering and asking questions in a way that the thinking is available to everyone in the room. Back to the story, in front of ten groups of 4 learners each, all sitting at their own tables, Blanca invites each learner to imagine what will happen if they introduce a *sealed container with something inside* and a *smaller and thinner sealed container*– she shows the objects A and B– in the aquarium that is full of water. First, she discusses with the kids all the possible outcomes. One child goes to the board and makes a drawing that illustrates the discussion: it is a representation of the aquarium and the 3 possible outcomes that they agree may occur. If the object stay on top of the water, they say it floats. If it is in the middle of the aquarium, they say it sinks. If it goes to the bottom, they say it sinks completely. Later, Blanca asks them to raise their hand if they think the first object will float. She counts the number of hands raised and writes the number followed by the symbol "F" in the second column of the poster. Then, she repeats the questions for the other possibilities and writes the number of questions for each possibility followed by "S" or "SC", depending on the case.

The **Learner Own Space –LOS**– are the moments in the classroom when the learners themselves are drawing, writing on their notebook, touching or looking objects, and reading books or browsing the Internet. They are talking to themselves and making decisions and thinking on their own. Continuing the story, each learner is writing, on the paper that Blanca gave them, their ideas about what will happen to each one of the objects in the water and explaining why they think this will happen in such way. Juan writes on his notebook that the *Object A* will sink because it is heavy. Maria writes that it will sink because it is heavier than the *object B*… Pablo looks around and seems not to be sure about what his answer will be.

I call **Shared Own Learner Space –ShOLS–** those moments when the learner and the teacher are sharing their ideas, asking questions and answering them, doing activities together. The teacher shows something to one learner, and asks questions. The student answers or asks questions, and shows things to the teacher. In the story, for instance, Blanca sees Pablo hesitating, so she goes to him and asks: "what are you thinking?" He answers: "I am not sure if it floats or if it just stays in the middle –showing the object A with his finger. I am sure that it will not go to the bottom". Blanca takes the object A and gives it to him. Pablo takes it in his hands and makes movements. Then, he says: "Now I know, it will stay in the middle." Blanca asks him: "Why do you think that the object A will stay in the middle of the water?"

By **Collective Group Space –CGS–** I mean the moments when the teacher addresses to all the groups of students by asking questions, sharing activities and promoting discussions. The teacher asks the group to share ideas about their common activities, and asks questions to them. In our story, Blanca says that each group must discuss their answers, agree on the one that seems the best for all the groups, and decide how the group will support their explanations. Then, she gives each group an aquarium full of water and the objects A and B. She asks each group to see what happens and to write one explanation for what they are observing. When all the groups have finished, she asks every group to stick their papers on the wall, and explain and communicate their thoughts to the other groups.

The **Group Own Space –GOS–** are the moments when two or more children are sharing ideas, talking, making activities together, or sharing a common task. Continuing the story, for example, Maria, Juan, Pablo and Ana, as a group following Blanca's instructions, are seeing that the Object A is in the surface of the water and the object B is in the bottom. Ana says happily to the others: “Yes! It is as I thought.” Maria and Juan seem surprised, and Pablo experiments pushing the object A to the bottom. The object returned to the surface after he stopped pushing it down the water. After they discussed and wrote their ideas on a poster, Ana went to the wall, stuck it to the wall and explained to the other groups what they had found.

Finally, I call **Shared Own Group Space –ShOGS–** those moments when the teacher talks and shares one activity carried out in one small group of learners. The teacher asks questions, looks whether there is agreement on the ideas or not, or points to a particular object and shows something that is happening. Back to the story, Blanca goes back to Maria, Juan, Pablo and Ana ‘s table and shows with the finger the object that is on the right side of the aquarium, asking: “why do you think this object is at the bottom?” Maria answers: “Because it is heavy”. Juan interjects: “No, it is because it is heavier than the other.” Blanca asks how can they know who is right between Maria and Juan. Pablo proposes to find out the weight of each object to see which one is the heaviest. They found out that the object A was heavier than the object B. Juan said: “I do not understand.” Maria asks Blanca: “Why?”

In what follows, I will interpret these different types of spaces happening in IBSE classrooms, with a focus on assessment, from two different theoretical perspectives. My intention is to evidence the shortcomings of theories of assessment focusing on the individuals’ cognitive change. I will show what a view of assessment building on socio-cultural theories can offer to interpret students’ learning.

THE INDIVIDUALISTIC POINT OF VIEW IN ASSESSMENT

One argument that supports the relevance of the IBSE educational approach is that the current way to teach science does not help students to change their understanding about the physical world. IBSE promotes a pedagogical structure that allows students to express their theories and explanations, building on previous experiences outside and inside the classroom, in order to develop argumentations that are more appropriate. This is, arguments should be expressed in a more scientific language (e.g. Furtack et al. (2007)). The purpose of assessment for learning, as part of this pedagogical structure, is to help each student to review and modify their conceptions by confronting their own explanations with evidences that either support or not their own view. For instance, a possible interpretation about Juan and Maria’s surprise when they saw the Object A floating, is that the theory they had built during their previous experiences does not work for this particular case. At the same time, it is possible to interpret that Blanca wanted to elicit their theories in order to give feedback to them, or provide them with new experiences that will help them to modify their own theories. Thus, she asked them to write, before they actually observed the objects in the water, their justifications for their prediction. What they wrote on the paper would open the door to the thinking happening in their head.

Figure 1 shows the constructivist model that is presented in some IBSE documents to support this view. Taking this model, one could interpret that when Pablo, Maria and Juan were writing their guessing about what would happen, they were using their existing ideas to predict. After that, when they worked in the group, they tested their existing ideas. In the case of Juan and Maria, the experimental evidence did not support their existing idea; however, for Ana, the fact that object A floated was the evidence that supported her existing idea, so it became stronger.

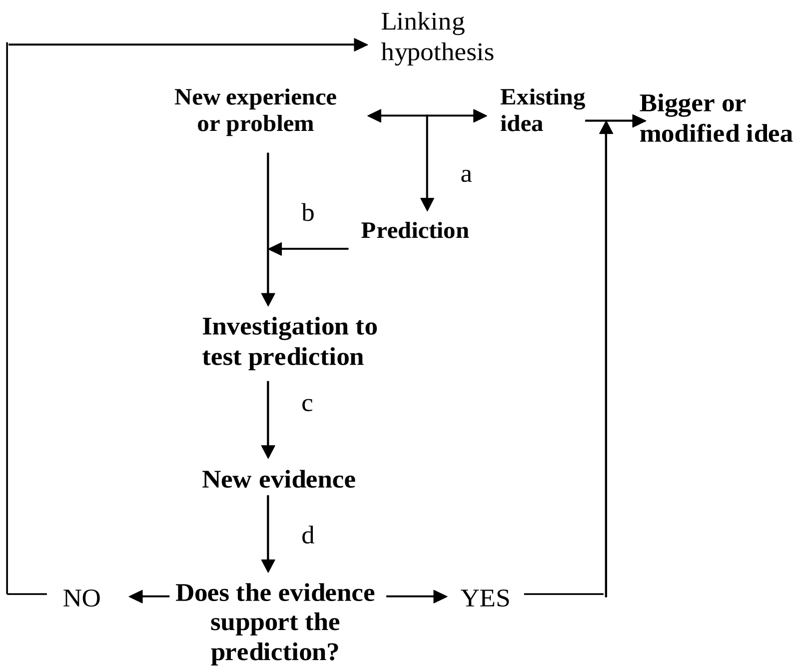

Figure 1. *The constructivist learning model used in some IBSE documents* (Harlen, 2007; Saltiel, 2006)

Besides the purely individual focus, social interactions have been important in the teaching model of IBSE. Children do not only learn by making sense of new experiences on their own, but also in collaboration with others. Social interactions actively develop children's own understanding with the spur of communication with others (e.g. Insight: An Elementary Hands-On Inquiry Science Curriculum, EDC Center for Science Education). For instance, one can imagine that during the test Maria and Juan will have a new hypothesis when talking to Ana and Pablo, due to the experimental evidence. In addition, one can interpret that when Blanca approached Pablo and gave him the object A, she was trying to show him that the properties of the object A could be relevant in order to predict. Or maybe, she wanted to encourage him to use his theory, which she expected to be that the mass of the objects influences the buoyancy.

For some IBSE researchers, assessment for learning is an important tool available to teachers to support students' conceptual change and modification of mental structures. The assumption is that when the students learn in constructivist environments, they experiment the "conceptual change" that will modify their mental structures. For instance, Shavelson et al. (2008) write: "We went beyond the usual definitions of science achievement as largely acquisition of declarative and procedural knowledge and evaluated the claim that formative assessment promotes conceptual change (p.299)… Their justifications and explanations reveal their schematic knowledge (knowing and reasoning why) and become the focus of classroom discussion with the goal of closing the gap in "mental models" for explaining what they saw, based on empirical data" (p.304).

In this approach the justifications and explanations produced by children reveal the thinking process expected; they provide evidence of "conceptual change". Relating back to the story, one could expect Blanca to collect information about the students' mental structure, to later try and stimulate discussions, activities, problems, etc., with the purpose of helping students constructing the idea that "what matters in the buoyancy phenomenon is the density of both the water and the object". The focus of the assessment process is on the explanations that students give during the class and how those explanations become part of the "classroom discussions". Somehow, those justifications and explanations externalize the mental models inside the individual mind. The interactions with external actions or agents will provide some feedback in order to change the structure into a more "adequate" structure. In the assessment for learning model, the role of the teacher is fundamental in eliciting, recognizing and giving feedback (Ruiz-Primo & Furtak, 2006), in order to direct the change process of mental models. The interaction with other learners is also an important mechanism of feedback.

In IBSE assessment models, it is relevant to inquire about the learning process of students in order to judge how far their understanding is from the learning goals. The final objective of the assessment is to take action in order to "close the gap" between stated learning goals and students' externalized justifications and explanations. The learning goals are expressed in terms of science contents, process skills, and attitudes. These elements constitute the knowledge that students are expected to acquire after several activities. The model assumes that, during the informal and formal moments of assessment, the children and the teacher need to share the learning goals so as to know where they are standing in relation to those goals; and in case they are not reaching the goals, to know how to get there.

This view of assessment for learning is what I call the individualistic point of view in assessment for learning (for uses of the term individual point of view in Mathematics and Science Education see Leach & Scoth (2003) and Radford (2008)). Although the teacher and the other students are important in the assessment process, the focus is the learning process happening in the head of the individual student. The conceptual change of each individual student is what matters at the end. The focus points on the individual learning process: skills, contents and attitudes. The significance of "the other" in the learning process is not taking into account.

It is interesting to notice that even though the IBSE teaching model emphasizes the importance of social interaction, assessment is mainly individual. Thus, there appears to be a disjunction between the espoused importance of "others" in the individual learning process in IBSE teaching models and the highly individualistic formulations of assessment. The interpretations that can be made of interactions and conversations in the different spaces promoted in IBSE classrooms seem to be limited in possibilities for acknowledging what may count as "evidence" of learning. In the following section, I will try different interpretations with the support of socio-cultural theories of learning in order to formulate some ideas of socio-cultural views of assessment for learning in IBSE settings.

THE SOCIO-CULTURAL POINT OF VIEW IN IBSE – ASSESSMENT FOR LEARNING

I will start by moving away from the basic assumption that the learning process happens in the head of the individuals. Rather, I assume that learning happens in the social spaces where subjects participate in social activities where cultural products are available for them in complex social and historical setting. According to socio-cultural theories, learning occurs while the subject, a fundamentally social being, participates in socially structured practices (James, 2006; Leach & Scoth, 2003; Radford, 2008). Therefore, I will acknowledge that "learning is by definition a social and collaborative activity in which people develop their thinking together" (James, 2006, p. 57). The core aspects that I will consider in my reflections about assessment for learning in IBSE are how students make sense of a situation in the daily classroom context, and what is the mechanism by which the participants in that situation can share meanings and interpretations of this situation.

For socio-cultural learning theories, "thinking is conducted through actions that alter the situation and the situation changes the thinking; the two constantly interact. Especially important is the notion that learning is a mediated activity in which the cultural artefacts have a crucial role" (James, 2006, p. 57). In that sense, symbols, concepts, cultural ways of talking, historical experiences of the subject and of the society, the historicity and framing of a situation, and the artefacts available in a particular moment guide our perception and the meaning that we are able to make of the different elements involved in a situation. Taking this into consideration, the development of scientific knowledge is not only constrained by empirical data emerging from experiments, but it is also socially validated by the language, the symbols, and the tools that are available in the scientific community in a particular historical moment. In that sense, scientific knowledge cannot be learnt from sensory experience alone (Leach & Scoth, 2003). A classroom community develops with time a shared history that provides the setting in which particular forms of thinking can emerge. Considering the learning of an individual outside of that context and setting is simply not possible.

For instance, the events in the story could be interpreted in another way. One could imagine possible thoughts of Ana, one of Blanca's students, when Blanca asked what would happen to the objects when put into the water. Ana probably recalled when her mother puts potatoes in a pot, and the water in it goes out while she observed the water pouring out of the aquarium when the objects were introduced into it. She may not have thought about the capacity of objects to float or sink. However, when the collective discussion took place and the different possible positions of the objects in the water were represented, she changed her thinking and became aware that she was thinking about another aspect of objects and water. Then, she remembered when her mother told her that when lentils are soaked in water, those that are in the surface have to be removed because they are bad. She may have thought that the same object can be in the bottom or in the surface, depending on how good or bad it is, as in the case of the lentils. So it was very complicated for her to decide where the object would be.

What Ana thought, was mediated by her history of interactions with water and objects in a particular social setting, with particular artefacts and languages available: in the kitchen, in a cooking session, with her mother's language and knowledge. She learned from her mother that there is good and bad lentils and that this may be recognized by the fact that ones float and others sink. At the same time, in another social setting, the classroom, she was learning a new social approximation to the relation between water and objects, helped by the others' experiences in their family, with friends or in that particular social setting. Those different experiences allow her to be aware of different ways of arguing, reasoning and thinking.

In order to move from the individualistic view in assessment to one that takes into account the socio-cultural nature of learning processes, I propose to focus on the learning happening in the diversity of social situations in IBSE classrooms. I will use the different IBSE classroom moments described previously, where learners are engaging with each other in social and physical settings: talking, thinking and doing with others, experimenting with different kinds of objects, using the languages they bring to the situation from out-of school experiences and the new ones that are available, and making sense of the activities they are doing together. I will assume that learning is rooted in the engagement among subjects and is happening in the shared activities, in a particular, socially structured setting. Knowledge is in the spaces of engagement among subjects. Knowledge and learning are not in the head of individuals.

I call *Spaces* of *Learning-in-Otherness* to those spaces that are generated while students and teacher are engaging with each other, in the physical and social setting of each moment of the IBSE classroom. The *Figure 2* shows the diversity of spaces that I recognized. Each space is constituted by *artefacts*, such as notebooks, board, posters, etc.; *semiotic symbols*, such as concepts, diversity of representations, etc. *activities* such as problems, challenges, etc.; *communication* such as body language, verbal language, written language, etc.; *emotions* as happiness, sadness, etc.; *social relationships* such as friendship, power relations, etc. Those spaces are interconnected, and teacher and students move between them during the class time.

			
Learning-in-otherness Own Space	**Shared Learning-in-otherness Own Space**	**Learning-in-otherness Own Group Space**	**Shared Learning-in-otherness Own Group Space**

		Teacher Learning-in-otherness Own Space	**Learning-in-otherness Collective Space**	**Learning-in-otherness Collective Group Space**

Figure 2. *Representation of Spaces* of *Learning-in-Otherness*

By formulating these spaces, I am trying to focus the attention on the thinking and learning taking place in the moments of engagement among subjects and not in each individual's head. At the same time, I make visible the situatedness of the knowledge that emerges from the activity: while the learners are engaged in writing, reading or looking at the objects in the water, their thinking moves and new possibilities for sense-making emerge.

For example, when Pablo is hesitating about the answer to Blanca's question, his thinking is emerging from the contact with the question, the presence of the objects A and B, and his own experiences in the past. All his thoughts are possible because of all these elements. Somehow, the thoughts are possible in that *Learning-in-otherness Own Space* between his thinking, the answer his writing and the question. At the same time, when Blanca went next to him asking: "what are you thinking?" and he explained that he was not sure about the answer, and then Blanca gave him the object A, another space of thinking (Shared *Learning-in-otherness* Own Space) is there between Pablo's thinking, Blanca's thinking, the object, the question and the notebook. In that way, Pablo had new information that came from the physical setting and the social interaction. For the *Spaces of Learning-in-Otherness*, you can imagine the same complex situation. Somehow, the spaces are interconnected; first, Blanca's question was addressed to all the children. Then, Pablo was thinking alone and writing and following that. After that, Blanca talked to him and gave him the object A. Pablo's thinking and learning evolved in that continuum.

If assessment is what is done in order to help students to learn, and the learning goals are not focused on the learning happening in the children's head, a new perspective for assessment can be thought when the focus is on the *Spaces of Learning-in-Otherness*. Thus, the assessment needs to consider that the students come to the class with a history of interactions with others in their particular cultural world, far from scientific culture. Those experiences mediate the way they see and analyze the activities and situations in the classroom. At the same time, the role of the activities in the collective learning and thinking process will be relevant for the assessment decisions, as well as the characteristics of the thinking and knowledge they are sharing.

Hence, my proposal is to focus the assessment on the *Spaces of Learning-in-Otherness*. In that sense, the assessment will assure that all the participants are making sense and interpreting each situation in a such way that they can be engage in the current activity. The teacher, as the one that knows why the situation is relevant for learning, needs to develop the ability to hear the inquiry thinking that is in those spaces, and make sure that the participants are interpreting the situation in a scientific way. The thinking will be in the notebook of a child, in the poster presented by the group, in the verbal interactions, in the final discussion in the classroom or on the board. Each *Space* of *Learning-in-Otherness* needs to be considered as an opportunity to make the participants aware of what is going on. The way in which the activities, homework, or tests are introduced and used will make the collective process of thinking happen in a different way. Those different opportunities need to be recognized in order to make them closer to the scientific thinking. Since inquiry thinking is not the natural way of thinking in the social settings where the kids normally interact, it is necessary to build bridges between their normal thinking and the new one. Assessment can be thought of as those bridges that the teachers are building day by day.

FINAL REMARKS

I showed that there are different possibilities to approach the assessment for learning in IBSE teaching, depending on the learning theory that is assumed. On one hand, I interpreted one assessment-teaching-learning situation using a constructivist and individualist model of IBSE: learning occurs when learners change their mental structures; modify their own ideas by interacting with the phenomena and during the interaction with other individuals. I argued that in this case, the assessment focus is on the learning process happening in the learners' heads. This will guide the assessment activities. I called that view the *individualistic point of view in IBSE assessment for learning*. In contrast, I interpreted the same assessment-teaching-learning situation from a point of view of socio-cultural learning theories: Learning happens while subjects participate in a social situation where the cultural artefacts and historical social experience of the learners and the teacher allow the participants to make new sense and new meaning to a particular situation. I defined the *Spaces of Learning-in-Otherness* in order to focus the attention of the assessment for learning process on the social spaces of engagement rather than on the students' head. This approach implies a new way of making assessments in the classroom, considering each space as a moment to be aware of the collective thinking that is taking place.

Further reflection has to be made in order to consider a different ways of interpreting assessment activities that have been considered as relevant for learning processes in Inquiry learning contexts. New possibilities for the development of activities in the classroom can be thought. At the same time, the assessment for learning and learning theories exposed are used in a theoretical perspective and not from the perspective of teachers that work in the diversity of cultural contexts where IBSE is growing.

AKNOWLEDGE
I want to thanks Paola Valero who made the paper possible with her contributions, comments, support and dialogues.

ABSTRACT

Smoking is a serious society problem that affects persons physically, psychologically and socially. The textbook is strongly rooted in school education and works like a "screen" that links the space between the pupil and the external reality. It provides pupils with handy information, well structured and systematized contents, in order to facilitate them to build their own learning. In this context, a comparative analysis of the information conveyed by textbooks from the 16 countries was carried out. They differ for their geographical distribution and their historical, political and socio-cultural development: 12 European countries (Germany, Cyprus, Estonia, Finland, France, Hungary, Italy, Lithuania, Malta, Poland, Portugal and Romania), 3 from Africa (Morocco, Mozambique and Senegal) and 1 from the Middle East (Lebanon). Results showed that Morocco is the only country which textbooks do not address the smoking issue. Only 11 countries present the three dimensions of tobacco consumption (physical, psychological and social effects), some omit the psychological dimension, others the social one and others both. The Finnish textbook is the one presenting the smoking issue in a rather balanced way. The results show differences in political, cultural and curriculum with regard to the way textbooks of different countries explore the tobacco problematic.

Keywords: *Health education, smoking prevention, textbooks, cultural diversity.*

INTRODUCTION

Epidemiological studies have confirmed the association between smoke consumption and several diseases such as those of the digestive, urinary, cardiac and respiratory tract as well as oncologic and psychosocial diseases. It is in such a high proportion that today tobacco consumption is the leading cause of illness and avoidable deaths, reducing life expectancy (WHO, 2009). Several international institutions like World Health Organization (WHO), UNICEF, UNESCO, Centers for Disease Control and Prevention in the United States (CDC), International Union for Health Promotion and Health Education (IUHPE) consider political and educational action to be the most powerful instrument for the prevention of smoking abuse prevention (IUHPE, 2008).

Being an essential link between the scientific knowledge selected for teaching (external didactic transposition) and the knowledge effectively taught in the classroom (internal didactic transposition) (Clément, 2006), the textbook works as a teaching instrument transferring cultural references to the school as it reflects the educational policies and the social interests. It is a cultural object that talks about the society in which it is included (Lebrun, 2007).

Although new ways of thinking and modern pedagogy criticize the intellectual bookish/encyclopedic pupils, the fact is that the textbook is considered by teachers, pupils, parents and governmental institutions as a fundamental and structuring instrument of the educational process and so, the most used pedagogical resource at school. Therefore the textbook is still strongly rooted in school education and plays the role of a "screen" that links the space between the pupil and the external reality, therefore becoming the centre of formal knowledge (Giordan, 1999). This gives the teacher an important role as he/she must assign an appropriate position contextualized with the teaching-learning process where the book should provide pupils with handy information, and well structured and systematized contents, in order to facilitate them to build their own learning (Perrenaud, 2005)

Accordingly, and particularly in the problem of tobacco addiction, the textbook can assume the role of a memorandum coordinator of facts and ideas built interactively over a lifetime and during classes, in order to complement the acquired knowledge as well as to provide useful reading and suggestive images. In this way, the textbook can contribute for the prevention of tobacco consumption, as smoking is a serious physical, psychological and social problem of modern society, particularly for children and young people who are more vulnerable (Precioso, 1999; Negreiros, 2000; WHO, 2009).

In this context, a comparative analysis of the information conveyed by textbooks from the 16 countries involved in the European project BIOHEAD-CITIZEN (Carvalho, 2004; Carvalho & Clément, 2007) was carried out, assuming that, overall, they convey the concepts and ideas of the national Health Education programmes (Gonçalves, 2008). The 16 countries involved in this project differ not only for its geographical distribution, but also and mainly by their historical, political and socio-cultural development: 12 European countries (Germany, Cyprus, Estonia, Finland, France, Hungary, Italy, Lithuania, Malta, Poland, Portugal and Romania), 3 African countries (Morocco, Mozambique and Senegal) and 1 of the Middle East (Lebanon).

To establish whether there are different approaches to the problem of smoking addiction and determine whether physical, psychological and social dimensions have identical treatment in textbooks of different countries, the following research question was formulated: Are there significant differences among the textbooks of the 16 countries regarding the way they address the tobacco problem?

METHODOLOGY

For the analysis of textbooks we used the specific part for tobacco of the Health Education grid (Table 1), developed in the FP6 STREP European project BIOHEAD CITIZEN (Carvalho, 2004). The following indicators were analysed: (*i*) physical effects, (*ii*) psychological effects, and (*iii*) social effects, (*iv*) anti-smoking campaigns and (*iv*) environment (Table 1).

These indicators were applied to a total of 76 textbooks where this topic was referred, in primary and secondary school, in the 16 countries involved in the project, distributed as follows: 3 from Cyprus (CY); 5 from Germany (DE); 2 from Estonia (EE) ; 1 from Finland (FI); 6 from France (FR); 5 from Hungary (HU); 11 from Italy (IT); 14 from Lebanon (LB); 2 from Lithuania (LT); 2 from Malta (MT); 7 from Morocco (MO); 2 from Mozambique (MZ); 1 from Poland (PO); 12 from Portugal (PT); 1 from Romania (RO) and 2 from Senegal (SN).

The number of occurrences in relation to the Biomedical model (BM) or the Biopsychosocial model (BPSM) of health were calculated by the occurrences of specific indicators for the BM (pathological, curative and preventive references) and for the BPSM (healthy life, empowerment, environment issues). Similarly, the number of occurrences of physical, psychological and social effects associated to the consumption of tobacco was calculated. Two separated analysis were conducted, one on the textual occurrences and the second on the images.

For each country, the data are the means of the occurrences of each group found (physical, psychological or social effects) in the totality of the analysed textbooks of the country, for either text references or images.

Table 1 - Grid with indicators for the data collection on Tobacco

Conceptions	INDICATORS	IMAGES No. occurrences	TEXT No. occurrences	ANNEX HE-3.2.n
3.1. SMOKING ABUSE	Unhealthy components of tobacco			
	Physical effects in the body: - Respiratory tract - Circulatory system - Nervous system - Fetus disorders (of smoking mother) - Lung cancer - Other diseases			
	Psychological and behavioral effects: - Anxiety - Addiction (dependence) - Others (specify)			
	Family disturbance: - Overspending, - Children's illness - Passive smoking - Mortality rates - Others (specify)			
	Anti-smoking campaign : - Information - Educational action - Legal rules - Promotion of healthy habits - Fear contents - Possible assistance (phone , number, website ...			
	Environmental (and social) approach: - Tobacco factories - Identifying images - Notion of pleasure during consumption			

RESULTS

Health Education in textbooks of 16 countries: Biomedical model (BM) and Biopsychosocial model (BPSM)

Finland is the only country where Health Education is a separate curricular subject. Therefore all pages (100%) of the analysed Finish textbooks were devoted to this issue.

About 55% of the Cypriot textbooks were devoted to Health Education whereas in the textbooks of the remaining 14 countries, this topic was below 30% (Figure 1).

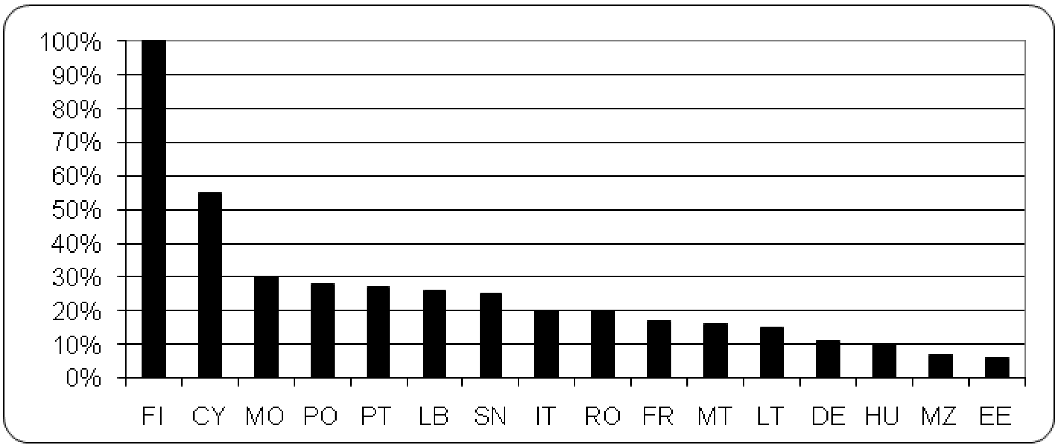

Figure 1- Proportion of the number of pages devoted to health in school textbooks of the 16 countries.

In what concerns tobacco addiction, the biomedical model (BM) of health (characterised by pathological, curative and preventive dimensions) prevails over the Biopsychosocial model (BPSM) of health (characterized by healthy life, empowerment, environment issues) in both textual and iconic elements of textbooks in 14 of the 16 participating countries (Figure 2). In fact, only textbooks books from Finland and Germany are the ones having more occurrences of HP than BM: 67% HP and 33% BM in Finish books and 63% HP and 37% BM in German ones (Figure 2).

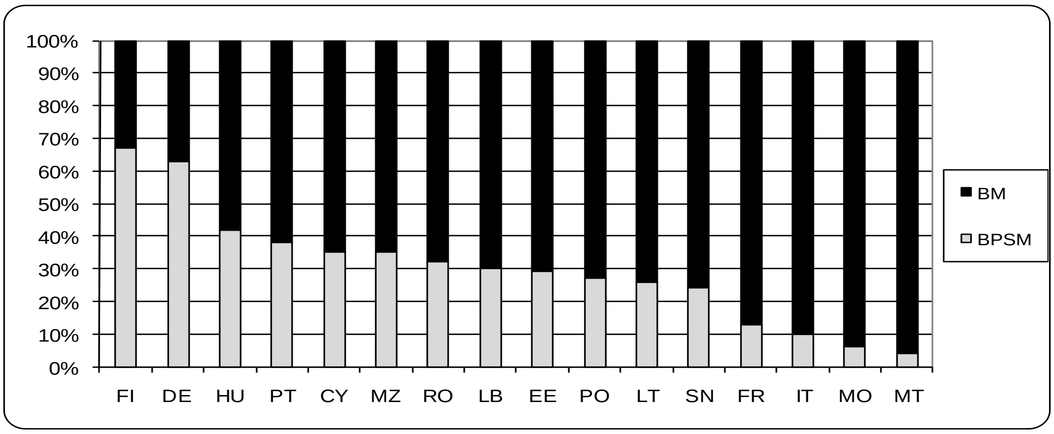

Figure 2- Biomedical Model (BM) and the Biopsychosocial model (BPSM) of health distinguished in textbooks of the 16 countries.

Physical, psychological and social effects of tobacco in textbooks of 16 countries

Text analysis

Finland stands out as the country whose textbooks present more text mentioning physical, psychological and social effects of tobacco (Figure 3). The physical effects of tobacco are the most frequently discussed in the text of all countries textbooks, followed by psychological and social ones (Figures 3 and 4).

Only 11 countries explore the three dimensions of the tobacco problem. The following 6 countries textbooks leave out one, two or the three dimensions of tobacco effects: French textbooks omit the psychological dimension and Lithuanian books the social dimension; Poland and Mozambique do not mention psychological and social dimensions while Moroccan textbooks do not mention any of the three dimensions (Figure 3 and 4).

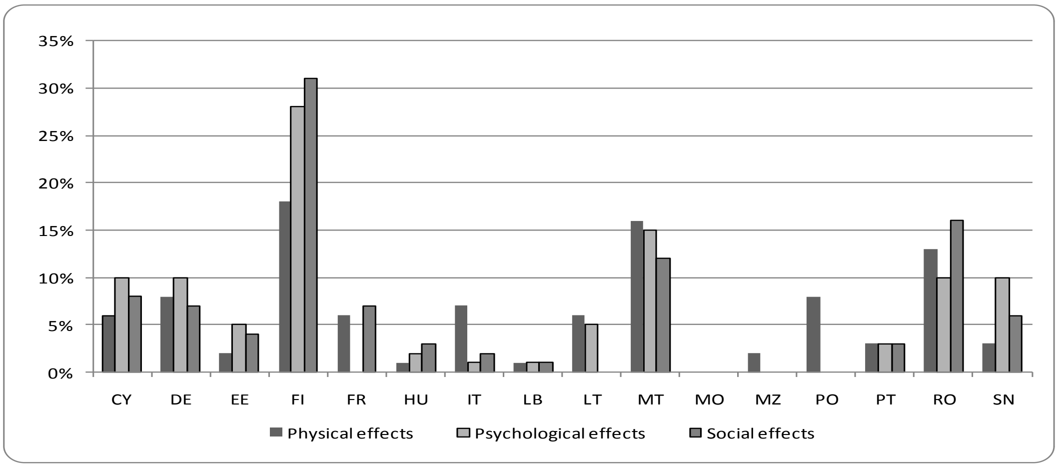

Figure 3- Contribution of each country for the total number of text occurrences of physical, psychological or social effects of tobacco.

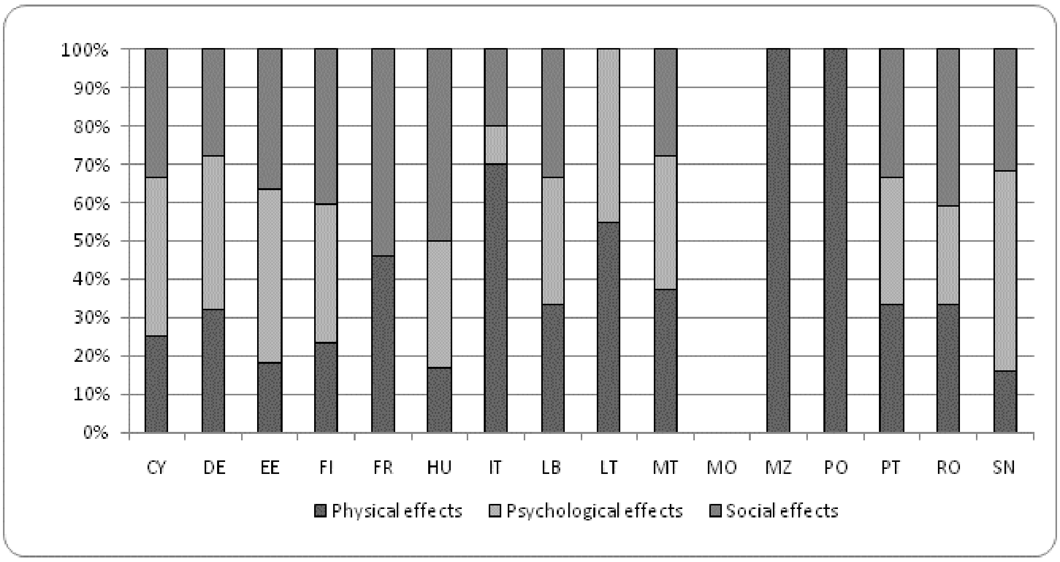

Figure 4- Proportion of text references of physical, psychological and social effects of tobacco in textbooks of each country.

Images analysis

Five of the 16 countries participating in this study (Estonia, Lithuania, Morocco, Mozambique and Poland) do not present images related to physical, psychological or social effects of tobacco and only 6 (Finland, Portugal, Germany, Hungary, Italy and Lebanon) explore the three dimensions of tobacco problem by images (Figure 5). Once again, the Finnish textbook is the one presenting more images related to physical, psychological and social consequences of tobacco consumption (Figure 5).

Despite the large discrepancy in values obtained for the images of physical, psychological or social impact, school textbooks in Germany, Finland and Portugal stand out as those with a better balance between the three dimensions (Figure 5 and 6).

In the case of the Estonian, French, Romanian and Senegalese textbooks, only the physical dimension of tobacco is shown in images (Figures 5 and 6).

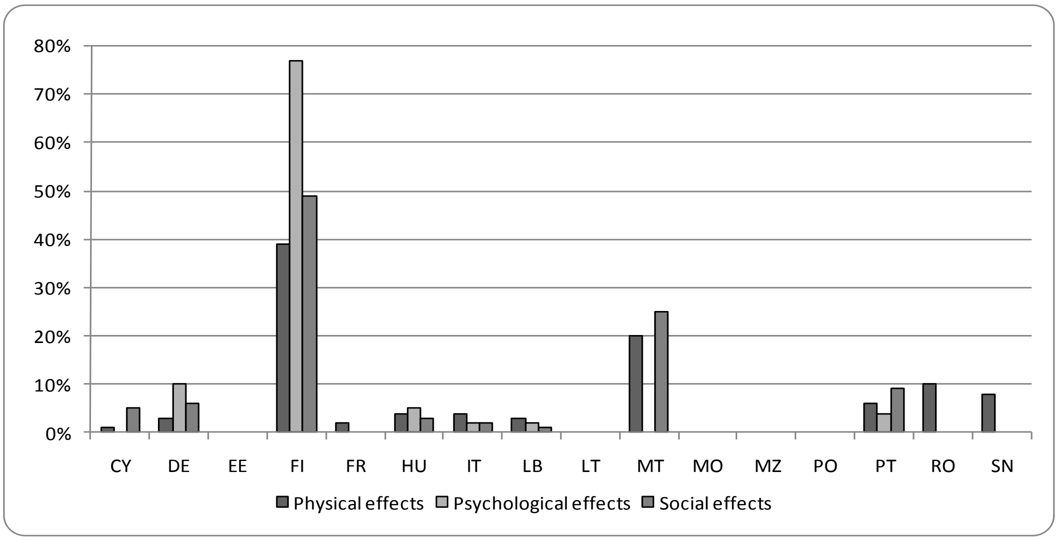

Figure 5- Contribution of each country for the total number of images of physical, psychological or social effects of tobacco.

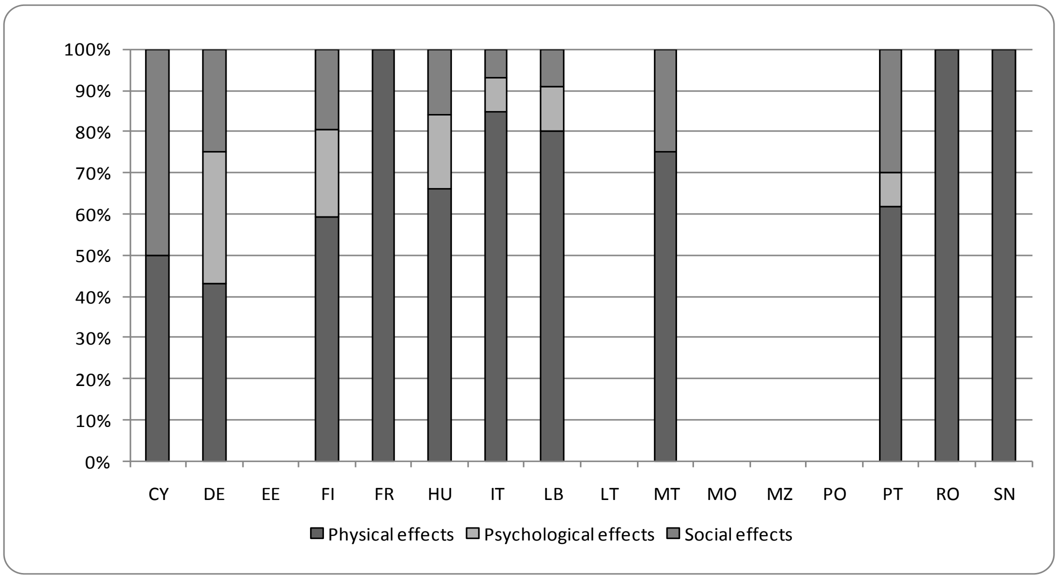

Figure 6- Proportion of images of physical, psychological and social effects of tobacco in textbooks of each country.

Anti-smoking campaigns and environment contexts in textbooks of 16 countries

Only six countries (Germany, Estonia, Finland, Hungary, Lebanon and Portugal) mention in their textbooks anti-smoking campaigns and refer some smoking environment contexts (Figure 7), such as smoking pleasure, smoking groups, tobacco production, tobacco factories, trade legislation, consumption legislation or associations for smoking dependents. Once again the Finnish textbook is the one that presents about 40% of total references to prevention campaigns and 37% of total environment contexts. As for the environments, the texts with more references are the ones from Germany (22%), Estonia (18%), Hungary (15%) and Portugal (5%).

In contrast, the analysed textbooks from France, Lithuania, Morocco, Mozambique and Poland do not incorporate textual references about prevention campaigns nor about the environment related to smoking. Romania, Malta, Cyprus, Senegal and Italy address only the topic of prevention campaigns (Figure 7).

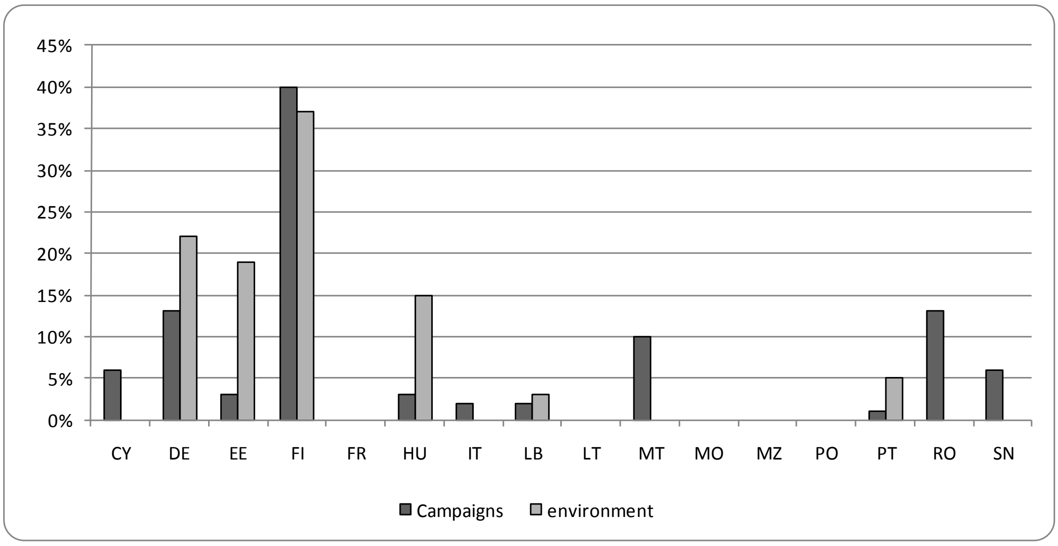

Figure 7- Contribution of each country to the total number of text occurrences of anti-smoking campaigns and environment contexts.

Textbooks from Germany, Finland, France and Portugal present images about anti-smoking campaigns and smoking environment contexts (Figure 8). The Finnish textbook is once more the one with more images from both campaigns (73%) and environments (60%) followed by the Germany textbook for the first issue (11%), France (6%) and Portugal (4%), and for environments the ones from France (20%), Hungary (11%), Germany (6%) and Portugal (3%).

In contrast nine other countries (Cyprus, Estonia, Lithuania, Malta, Morocco, Mozambique, Poland, Romania and Senegal) do not show images concerning both issues (Figure 8). Italian (3%) and Lebanese (2%) textbooks refer only to anti-smoking campaigns while the Hungarian textbooks include only images of smoking environments (12%).

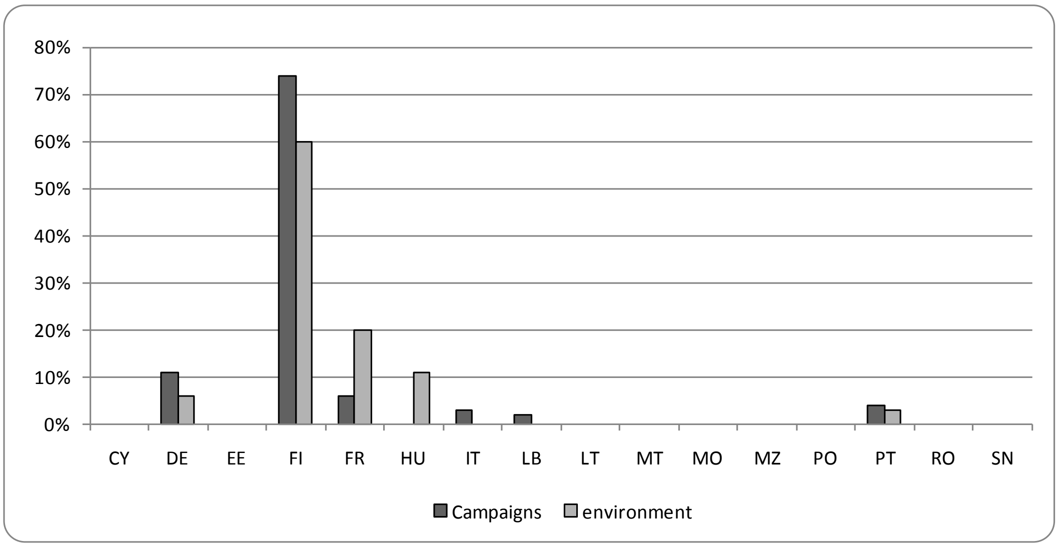

Figure 8 - Contribution of each country for the total number of images of anti-smoking campaigns and environment contexts.

CONCLUSIONS AND DISCUSSION

Of all countries involved in this study, Finland is the only one having a separate curricular subject of Health Education and so the textbook devotes 100% of its content to this subject. The majority of the Finish book as well as the German book (66% and 63%, respectively) express explicitly or implicitly the contemporary Health Promotion view whereas the other countries textbooks are mainly within the classical Biomedical Model. In addition the Finnish textbook is the only one exploring the smoking issue in a rather balanced approach with regard not only to the three health dimensions (physical, psychological and social dimensions) but also to the emphasis given to anti-smoking campaigns and smoking environment contexts.

Morocco is the only country in which textbooks do not address the smoking issue. This may be due to the fact that smoking is a rather common and well accepted male habit in the country.

Of the 15 countries referring to this issue, only 11 countries present the three dimensions of tobacco consumption (physical, psychological and social consequences), some omit the psychological one while others the social one and others both.

In all countries the physical, psychological and social effects of smoking are treated in more detail than the anti-smoking campaigns and smoking environment contexts, in both space (text and image occurrences) and depth of analysis.

In the universe of analysed textbooks only few mention the existence of institutions to help smokers stop smoking. This seems to be a serious gap, since for many pupils the textbook may be the most important source of information they have access to.

The data among the 16 countries indicate that there are different cultural and educational policies in the approach to smoking addiction either in the field of prevention of starting smoking and in the combat for stopping smoking.

On the whole, the present study indicates that the Finnish textbook is the one which presents the smoking issue in a rather balanced way. This study is mainly a quantitative approach therefore a qualitative analysis should be carried out in more detail in order to evaluate whether this Finnish textbook could be taken as an example of good practices regarding the approach to the smoking issue. Therefore it might be considered a model to other countries textbooks, with some adaptations to their specific socio-cultural background.

ACKNOWLEDGEMENTS

This work had the financial support of the European project FP6 Biohead-Citizen CIT2-CT-2004-506015 and the Portuguese FCT project (“Analysis of school textbooks” PTDC/CED/65224/200).

The authors particularly thank the colleagues who gathered data or coordinated this process concerning the topic "Health Education" in the textbooks of their respective countries: Nicos Valanides (Cyprus), Kai Pata and Tago Saraparuu (Estonia), Anna-Liisa Kosonen (Finland), Dominique Berger and Pierre Clément (France-Lyon), Claude Caussidier and Daniel Favre (France-Montpellier), Christine Geier and Franz Bogner (Germany), Dániel Horváth and Attila Varga (Hungary), Adriana Valente, Luzi Daniela and Silvia Caravita (Italy), EL-Hage Fadi and Odile Saab (Lebanon), Grita Skujiene and Jurga Turcinaviciene (Lithuania), Desireè Scicluna Bugeja and Paul Pace (Malta), Sabah Selmaoui (Morocco), Elwira Samonek-Miciuk (Poland), Adrienne Kozan (Romania), Mame Seyni Thiaw and Valdiodio Ndiaye (Senegal).

DISTRIBUTED COGNITION: SCIENTIFIC INVESTIGATIONS OF PRIMARY SCHOOL STUDENTS IN DUO CONTEXT

Andreas Chiras

ABSTRACT
Sixty dyads consisting of two sixth-grade students were instructed to interact with a device and investigate its functioning. The students were explicitly instructed to think aloud prior and after any experiment with the device, to keep a record of their observations and to jointly decide how to proceed with their investigations. At the end of the investigation, each dyad was required to report its final conclusions concerning the functioning of the device. This procedure was based on Klahr and Dunbar's (1988) study, who conceptualized scientific investigation as a dual search, a search in a space of hypotheses and a search in a space of experiments. The results of the study clearly demonstrated primary school students' limitations in terms of cognitive abilities, or in terms of reporting their experimental data and using their records as an external memory system. The results also indicated several factors that contribute or inhibit the functionality of a joint cognitive system in terms of both their social (persons) and material dimensions (the device), and clarified issues relating to distributed cognition.

Keywords: *Distributed cognition, joint cognitive system, scientific investigation*

INTRODUCTION
Traditionally, science education has systematically put emphasis on the mechanistic acquisition and accumulation of content (Valanides, 2003). Science is usually presented as a rigid body of facts, theories, and rules to be memorized and practised, rather than a way of knowing about natural phenomena (Van Driel, Beijaard & Verloop, 2001). Science learning experiences are mostly isolated from everyday life (Reif & Larkin, 1991) and, hence, do not enable students to apply in their personal lives outside the school what they learn in school (AAAS, 1990). Recent reform science documents emphasize the need to bring scientific inquiry experiences into science classrooms (National Research Council, 1996, 2000). Participation in inquiry can help learners acquire scientific reasoning skills, such as, experimentation, formulating questions, making observations, collecting and analyzing data, using logical and critical thinking to formulate conclusions, evaluating alternative explanations, recording and interpreting data, and many others (Zimmerman, 2000, 2005, 2007). These reasoning skills are crucial for the preparation of scientifically-literate citizens who can effectively participate in public discourse and decision-making regarding science-related social issues (American Association for the Advancement of Science, 1990, 1993; Hogan, 2002).

Klahr and Dunbar (1988; Dunbar & Klahr, 1989; Klahr, 2000) considered scientific reasoning as problem solving involving search in two coordinated spaces, the hypothesis space and the experimental space. The hypothesis space represents all possible hypotheses, and the experimental space represents all experiments that can be conducted. Prior knowledge and experimental results guide the search in the hypothesis space, while a current hypothesis guides the search in the experiment space and can lead to the generation of new hypotheses. This model has three basic components: search in the hypothesis space, search in the experimental space, and evaluation evidence. Each component entails different processes with different results. Searching the hypothesis space entails looking for a plausible hypothesis, and results in a particular hypothesis to be tested. Testing this hypothesis entails searching the experiment space for an appropriate experiment, and results in confirmatory or disconfirmatory evidence for that specific hypothesis that provides the grounds for a decision process concerning the acceptance, rejection or modification the hypothesis.

The fundamental assumption of traditional cognitive theory is that cognitive processes are internal processes and the unit of analysis has been always the individual cognitive system. Cognitive psychologists tried to explain how information is represented inside the human cognitive system, and decode the way in which these representations are transformed, combined and processed inside the system (Simon, 1969). Under this framework, the social and cultural context is left out of the analysis.

In contrast, the theory of distributed cognition considers the “joint cognitive system” as the unit of analysis (Hutchins, 1995a, 2005b; Norman, 1993; Pea, 1993; Salomon, 1993). Flor and Hutchins (1991) argued that distributed cognition is devoted to the study of how knowledge is represented both inside the heads of individuals and in the world (environment, culture, social interactions), the transmissions of knowledge between different individuals and artefacts, and the transformations that external structures undergo when acted upon by individuals and artefacts. Studies of group cognition in natural settings indicated that cognitive processes may be distributed among the members of a social group. They may also involve coordination between internal and external (material or environmental) structures. Cognitive processes can also be distributed through time so that the products of earlier events can transform later events (Hollan, Hutchins, & Kirsch, 2000).

In a joint cognitive system, the artefacts and the individuals are considered only as parts of an extended cognitive system that interact to produce cognitive work (Hollnagel & Woods 1983; Woods, Johannesen, Cook, & Sater, 1994; Woods & Roth 1988; Rasmussen, Pejtersen, & Goodstein, 1994). This joint cognitive system is cognitive in the sense that it processes information to execute cognitive tasks. Information processing, however, is not the sum of the operations of two or more independent components. On the contrary, information processing is distributed between the artefacts and the individuals who work together to produce behaviour. Dowell and Long (1998) argued that this cognitive work is simultaneously accomplished by all components of the joint cognitive system and in such away that a change in one of the components of the joint cognitive system has always implications on the distribution of cognitive functions.

Pea (1993) distinguished between two dimensions of distribution of cognition: a social dimension and a material one. The material dimension of the distribution refers to the incorporation of all kinds of mental and physical artifacts in which cognition is encapsulated, while the social dimension of the distribution refers to the involvement of social others who assist by functioning as cognitive resources.

The present study was guided by the Klahr and Dunbar model (1988) and took into account the notions of distributed cognition and joint cognitive system, and attempted to evaluate and compare the performance of the components (social and material) of a distributed cognitive system. The study also focused on the underlying cognitive processes operating when primary school students conduct investigations and on identifying factors that may hinder or support the optimal functioning of a joint cognitive system taking into consideration both its social (students) and material (a device) dimensions.

METHODOLOGY

A sample of 520 sixth-grade students were initially administered the Raven's Progressive Matrices (RPM) and, based on their performance, a smaller sample of 120 students was selected. These students were assigned in 60 dyads, where 20 dyads consisted of students who had high performance on RPM H-H, 20 other dyads consisted of students who had low performance on RPM L-L, and the remaining 20 dyads consisted of one student having high and another student having low performance on RPM H-L. These dyads were instructed to interact with a device and investigate its functioning. The device consisted of a wooden box with eight light bulbs in a line and five switches in another line underneath. The bulbs and the switches were connected in a hidden circuit inside the box, while a red button beneath the switches was to test which lamp(s) was (were) lit on. In the circuit, one of the switches was connected as a general switch, while another switch was a dummy one. The students were explicitly instructed to think aloud prior and after any experiment with the device, and to keep a record of their experiments and the consequent results. The students had to jointly decide how to proceed with their investigations. At the end of the investigation, the students were required to report about their final conclusions concerning the functioning of the device.

Data were collected with observations and think-aloud protocols, as the students were jointly investigating the functioning of the device. Qualitative methods were employed to analyze the interactions among students and between the students and the device. The software ENVIVO was initially used for an in-depth qualitative analysis of the audio-taped think-aloud protocols that were consequently transcribed. The software INSPIRATION was also used for visually representing the kind of interactions and the different thinking elements that the members of each dyad exhibited, as they were attempting to investigate the functioning of the device. These representations in conjunction with the transcribed think-aloud protocols were also used to compare the role and the contribution of the students, as well as the role of the device as a source of data and how it continuously guided students' attempts to understand its functioning.

RESULTS

Each investigation was divided into interaction sequences representing units of dialogue that began when a student formulated a hypothesis, made an observation, proposed an experiment, formulated a prediction etc, and at least one statement from the other student followed the initiating statement. An interaction sequence ended when a student stepped back from the flow of the interaction by posing a new idea that diverted the discussion to a different idea. Every time a new or an alternative hypothesis was formulated or a new experiment was proposed etc, a new interaction sequence began, because these statements always indicated a pulling back from the flow of the dialogue. Based on the interaction sequences, two types of interaction sequences were distinguished: "collaborative" or “competitive.” An interaction sequence was coded as “competitive” when a student initiated something and the other student responded to him by (a) simply agreeing with the statement, (b) passively or neutrally acknowledging the statement, (c) repeating the preceding statement verbatim, (d) expressing a disagreement without justification, and (e) proposing something irrelevant. Within collaborative interaction sequences, both students contributed substantially to the discussion in such away that both students were equally or almost equally responsible for the outcome of the sequence. A coding scheme was thus developed and progressively refined. Then, two independent coders coded 20% of the investigations. The inter-coder reliability (Guba, 1981) between the two coders was 0.84. Disagreements were then resolved through discussion, and one of them completed the coding of the remaining investigations.

The “Degree of Collaboration” for each dyad was then calculated. Operationally, the “Degree of Collaboration” was defined as the number of collaborative interaction sequences, divided by the total number of the interaction sequences in an investigation. The results of the study indicated that the mean of the “Degree of Collaboration” for each dyad was 0.149 (SD= 0.143), which implies that the students spent most of the time during the investigation working competitively. Particularly, the mean of the Degree of Collaboration for H-H dyads was 0.263 (SD= 0.154), for H-L dyads was 0.113 (SD= 0.113), and for L-L dyads was 0.069 (SD= 0.068), respectively. A one-way ANOVA analysis was used to compare the mean of the Degree of Collaboration among the three types of dyads. The results indicated that there was a significant difference in the Degree of Collaboration among the three types of dyads [$F(2, 57)= 15.072$, $p = 0.000$]. Post hoc comparisons using Scheffe test showed that the mean of the Degree of Collaboration for H-H dyads was significantly higher than the mean of the Degree of Collaboration for the other two types of dyads ($p<0.05$). However, there was no significant difference between the mean of the Degree of Collaboration of H-L and L-L dyads. The findings indicated that students in H-H dyads were collaborated in higher degree than those who were paired in L-H and L-L dyads.

Based on the Degree of Collaboration, each investigation was divided in four different stages. In Stage 1 (Initial Investigation), the students worked competitively. During the Initial Investigation three different ways of work were detected: (a) in 35 dyads, the students followed the same way of thought, but without taking into consideration each other’s opinion, (b) in 9 dyads, the students followed a different way of thought, without any effort to investigate how the other was thinking, and (c) the students in 12 dyads used a combination of the two previous ways. Initially, the students followed the same way of thought, but later each one followed his own way of thought, while, at the end, followed the same way of thought.

In Stage 2 (Intermediate Investigation), the students began efforts to collaborate, and to take into consideration each other’s opinion, but, in some cases, they continue to work competitively. Thus, Stage 2 was characterized by an alternation of episodes in which the students collaborated and episodes in which the students worked competitively.

In Stage 3 (Collaborative Investigation), the students managed to collaborate continuously. Thus, they not only took into consideration each other’s opinion, but also took advantage of their "external memory system," and the information that was provided by the device. At the end of investigation, and after the students reported their final conclusions concerning the functioning of the device, the researcher prompted the students to re-examine their data and draw any additional conclusions. This part of the investigation was considered as a fourth and separate stage (Collective Review).

The majority of the investigations (n= 38) included only the stage of Initial Investigation. Ten investigations included two stages (Initial and Intermediate Investigation) and only 12 other investigations included three stages (Initial, Intermediate and Collaborative Investigation). Finally, in 9 out of 60 investigations, the students managed to take advantage of the stage of Collective Review. The majority of H-H dyads (n= 11) included three stages (Initial, Intermediate and Collaborative Investigation), indicating that these students managed to collaborate during the investigation. Besides, three from these dyads took advantage of Collective Review. On the contrary, the vast majority of the H-L (n= 15) and H-H (n= 16) dyads, respectively, included only the stage of Initial Investigation, indicating that these students were working competitively throughout the whole investigation.

Thirty dyads identified the general switch (GS). Especially, 17 H-H dyads, 12 L-H dyads and only one L-L dyad succeeded to identify the general switch. The vast majority of these dyads (n = 25) identified the GS during the Stages 1 and 2. Furthermore, 14 dyads managed to identify the GS by coordinating their hypothesis and collected evidence, while the rest 16 dyads examined the collected evidence to identify the general switch. Only 8 H-H dyads gave the GS the right name and explained how it worked. The remaining dyads supported that the particular switch "is a magic switch which when it is placed on the down position, a bulb is light up," "it is a source of electrical energy, which provides each bulb with an amount of energy to light up" or "it distributes electric energy to all bulbs."

Only 20 dyads identified the "dummy" switch (DS). The majority of these dyads (n= 14) was H-H type. On the contrary, only 6 L-H dyads and none L-L dyad managed to solve the problem of the DS. Only three dyads identified the DS by coordinating their hypothesis with the collected evidence, while 17 dyads identified the DS after examining the collected evidence. Two of these dyads considered that the particular switch played a vital role in the circuit, because "it could make the bulbs light up twice," while 18 dyads comprehended that the particular switch was not connected to the electric circuit and supported that "it doesn't work," "it is usefulness," or "it is dummy one."

The students of 52 dyads preferred to perform experiments that would generate a result or would make a lamp to light on, based on their hypotheses. This tendency is known as confirmation bias (Wason, 1960) or as positive-test strategy (Klayman & Ha, 1987). The remaining 8 dyads employed a negative-test strategy, that is, they performed experiments that could disconfirm their hypotheses. An example of the negative-test strategy was employed by the dyad $H\text{-}H_{11}$:

H_{21}: I think that a bulb always light up, when the switches 1 and 3 are placed on the down position.

H_{22}: I suggest to place the switch 3 on down position and the switch 1 on up position (all the other three switches were placed on up position) to find out if you are right.

H_{21}: I agree.

H_{22}: Let's do it. (After the experiment) Bulb 2 light up. Unfortunately, you were wrong. I conclude that a bulb light up when only the switch 3 (general switch) is placed on down position.

H_{21}: I agree.

In the previous dialogue, student H_{21} formulated the hypothesis that "a bulb always light up, when the switches 1 and 3 are placed on the down position." If the students proceed to test this hypothesis by executing experiments using the positive-test strategy (i.e., DUDUU, DDDUU, DUDDD), (the five letters represent the five switches of the device and U refers to the up position and D refers to the down position), this hypothesis would be confirmed, even though it was wrong, because a bulb would light on since the general switch (switch number 3) was on the down position. The students (H_{21} and H_{22}) executed an experiment that they expected to disconfirm their proposed hypothesis. Thus, they not only rejected this hypothesis, but they also progressed in identifying the GS.

The careful analysis of the investigations showed that students did not take full advantage of the available information. Instead, they chose to take into consideration only the information that was provided by their positive experiments, that is, experiments where a bulb lit up and considered that the negative experiments did not provide any useful and relative information. The students in 17 dyads formed at least a hypothesis with the possibility of a negative experiment. These students were characterized, according to Schauble, Klopfer, and Raghavan (1991), as engineers, because they manipulated variables in order to generate a specific outcome instead of trying to understand how the device functioned.

The deep analysis of the investigations revealed that the students did not take full advantage of their external memory system. Almost all students belonging in H-H dyads (n = 18) and a large proportion of students belonging in H-L dyads (n = 12) took advantage of the experimental results: (a) to identify one or both special switches (general and "dummy" switch), (b) to identify experiments that they had not executed before and, (c) to avoid the execution of repeated experiments. On the contrary, the students in L-L dyads often trusted their memory to obtain the needed information for testing their hypotheses.

In this task, the experimental space consisted of 32 (2^5) possible experiments, which represented all the different combinations that could be generated using the five switches and their two possible positions (up and down). The number of possible experiments could be reduced to 16 experiments if someone knew from the beginning which switch was the general or the "dummy" switch, or the experimental space could be reduced to 8 experiments if someone knew from the beginning both the general and the "dummy" switch. Each dyad conducted a number of experiments during the investigation. The mean number of performed experiments for each dyad was 25.42 (SD= 7.45) experiments. Particularly, the mean number of performed experiments for H-H dyads was 21.10 (SD= 5.29), for H-L dyads was 24.05 (SD= 6.41) and for L-L dyads was 31.10 (SD= 6.89), respectively. A one-way ANOVA, with the number of performed experiments as dependent variable and the type of dyad as independent variable, was performed. The results indicated that there was a significant difference in the number of performed experiments among the three types of dyads [$F(2, 57)= 13.591$, $p= 0.000$]. Scheffe post hoc analysis showed that H-H and L-H dyads performed fewer experiments than L-L dyads ($p<0.05$). However, there was no significant difference between the means of performed experiments of H-L and L-L dyads ($p>0.05$). This finding is justified by the fact that nearly all H-H dyads (n= 19) and a large proportion of (L-H) dyads (n= 12) managed to identify either one or both switches (general and "dummy" switch) which helped them to restrict their experimental space. These dyads also took full advantage of their collected data and avoided to perform identical experiments. On the contrary, L-L dyads performed more experiments, some of them were identical, and the majority of these dyads (n= 19) did not manage to identify the GS and the DS.

In spite the fact that the students recorded their experimental results, almost all dyads performed some identical experiments. Only 8 out of 60 dyads did not perform any identical (repeated) experiment. The average number of identical experiments was 5.07 (SD =4.73). Particularly, the mean number of repeated experiments for H-H dyads was 2.05 (SD= 2.37), for H-L dyads was 3.90 (SD= 3.55) and for L-L dyads was 9.25 (SD= 4.67), respectively. A one-way ANOVA, with the number of repeated experiments as dependent variable and the type of dyad as independent variable, indicated that there was a significant difference in the number of repeated experiments among the three types of dyads [$F(2, 57)= 20.957$, $p= 0.000$]. Scheffe post hoc analysis also indicated that H-H and L-H dyads performed fewer identical experiments than L-L dyads ($p<0.05$), but there was no significant difference between the mean number of identical experiments between H-L and L-L dyads ($p>0.05$).

Dyad's ability to control variables was also examined. A dyad was considered that employed the control of variables strategy when in two successive experiments moved only one switch. For each dyad the percentage of their experimental trials in which the students employed the control of variables strategy was calculated. The results indicated that the dyads used the control of variables on average of 24,6% (SD= 14,0%) of their experimental trials which indicated that students used the control of variables strategy in a small proportion of their experimental trials. Particularly, the mean number of experimental trials in which the students employed the control of variables strategy for H-H dyads was 27,7% (SD= 9,0%), for H-L dyads was 29,6% (SD= 17,96%) and for L-L dyads was 16,4% (SD= 10,4%), respectively. A one-way ANOVA with the control of variables as dependent variable and the type of dyad as independent variable, was performed. The results indicated that there was a significant difference in the control of variables among the three types of dyads [$F(2, 57)= 20.957$, $p= 0.000$]. Post hoc comparisons, using Scheffe criterion, were subsequently performed and revealed that H-H and L-H dyads employed the control of variables strategy in higher proportion of their experimental trials than L-L dyads ($p<0.05$). There was no significant difference between L-L and H-L dyads concerning this variable ($p>0.05$).

Students' ability to move the switches up and down systematically was considered as a measure of their combinatorial reasoning. The students in 16 dyads exhibited limited combinatorial reasoning, because during the experimentation with the device, the students moved the switches up and down randomly. For example, the students of H-H_3 dyad performed the following sequence of experiments: UUUUU, DDDDD, UDUDU, UUDDU, DDDUU, UUDUU, DUDUU, UDDUD, UDDDD, DUDDD. It is obvious that these students did not move the switches up and down in a systematic pattern. The students in 35 dyads exhibited in some degree their combinatorial reasoning and only the students in 9 dyads were able to employ a more developed combinatorial reasoning. For example, the students of H-H_6 dyad, initially, performed a sequence of five experiments in which only one switch was placed on the down position. Then, they performed a sequence of nine experiments that only two switches were in down position (DUDUU, DDUUU, DUUDU, DUUUD, UDUDU, UDDUU, UDUUD, UUDDU, UUDUD), followed by a sequence of five experiments that only three switches were in down position, and finally they performed a sequence of three experiments where only four switches were in the down position.

CONCLUSIONS

The findings of the study clearly indicate that students assigned to H-H and H-L dyads had significantly better performance, in terms of several variables (number of performed experiments, number of repeated experiments and combinatorial reasoning), than students assigned to L-L Besides, there were no significant differences in terms of these variables between students assigned to H-H and H-L dyads. Besides, students assigned to H-H dyads outperformed students assigned to H-L and L-L in terms of identifying the GS and the DS.

Another important conclusion was that the students spent most of the time during the investigation working competitively. Only the students assigned to H-H dyads managed to collaborate, but the collaboration was developed at the end of investigation (stage of Collaborative Investigation). Based on the Degree of Collaboration, each investigation could be divided in four different stages. In Stage 1, the students worked competitively, in Stage 2, the students began efforts to collaborate and to take into consideration each other's opinion, and, in Stage 3, the students managed to have a better and continuous collaboration. At the end of investigation, and after the students reported their final conclusions concerning the functioning of the device, the researcher prompted the students to re-examine their data and draw any additional conclusions. This part of the investigation was considered as a fourth and separate stage. The results indicate that the dyads were not functioning effectively, since, for the most part, only one of the two students in each dyad was actively engaged in the learning activity, whereas the other student seemed to be a passive observer.

The results of the study also demonstrate that primary school students have limitations in terms of several cognitive abilities. The students in a number of dyads managed to solve the problem, but they faced a lot of difficulties during their investigation. Many dyads exhibited an overall difficulty with dropping an initial hypothesis and stating an alternative hypothesis. Some dyads insisted till the end of their investigation that they could light up simultaneously either all the bulbs or multiple bulbs. Furthermore, they were not able to state or adapt hypotheses on the basis of data gathered or to verify their hypotheses based on contradictory evidence. Many dyads were prone to confirmation bias, that is, they tended to search exclusively for confirmatory evidence, while ignoring discrepant evidence, and failed to revise their hypothesis even in the presence of strong non-confirming evidence. Besides, the vast majority of dyads considered that the information provided by the negative experiments was not useful for their investigation. A lot of dyads did not take full advantage of their external memory system and performed some repeated experiments or redundant experiments. Almost all dyads used the control of variables strategy in a small proportion of their experimental trials and tended to vary too many variables (switches) over experiments, making the interpretation of outcomes virtually impossible. Also, their combinatorial reasoning was not fully developed, since they did not move the switches systematically.

The declared objectives of elementary science education curriculum in Cyprus is the acquisition of science process skills and the dominant teaching practice is the collaborative learning (Cyprus Ministry of Education and Culture, 1994). The total results of the present study suggest that the existing science curricula failed to achieve the ***declared objectives of science teaching. Zimmerman (2005) stressed the need to*** incorporate more authentic features and numerous composite skills in science teaching. Chinn and Malhotra (2001) argued that if schools do not focus on these features, then the cognitive processes developed will be very different from those used in real inquiry and antithetical to that of authentic science.

Additional research efforts will be needed to determine in what order such skills can be mastered, and which early acquisitions are most effective at supporting the development of subsequent acquisitions. Valanides and Angeli (2008) proposed that more research evidence is also needed to produce a more accurate picture of collaborative inquiry using more or less authentic scenarios, so that the role of communication and the inquiry processes at the level of a cognitive system are clearly highlighted.

ABSTRACT

This study was conducted to investigate the effects of problem-based learning approach in elementary science education on students' higher order thinking skills. The study was conducted on 6th grade students from an elementary school in Konya, Turkey in the second semester of 2005-2006 educational year. According to Science achievement test that was done before the application two equal classes were selected. While problem-based learning was implemented in one class, traditional methods were implemented in the other. The study was designed according to the pretest-posttest with control group model. An achievement test prepared in accordance with target behaviors of the chapter entitled "Static Electricity" in the unit "Electricity Guiding Our Life" in Science and Technology course was used as testing tool. The test was administered to the experimental and control groups as pretest and posttest. Data obtained after an application that lasted 6 weeks were analyzed by using t-test. Results showed that, problem based learning was more effective than traditional instruction in student achievement in comprehension level. Furthermore, problem based learning was found to be more successful than traditional instruction in improving problem solving and science process skills.

Keywords: *Elementary Science Education, Problem-based Learning, Higher-order thinking skills*.

INTRODUCTION

Problem Based Learning (PBL) aims specifically at improving problem solving and comprehension skills. This approach introduces people with various problems which they are likely to encounter in real life and the principles of solving those problems. PBL enables people to develop a high level of understanding on the subject by solving the problems related to the subjects (Copland, 2000: 535). Problem based learning has been shown to improve the analysis, synthesis and lifelong learning skills (Harland, 2002).

Finkle and Torp define problem based learning as a process that make people face with ill defined problems which reflect real-life problems. PBL engages problem solvers actively by giving them responsibility of their own learning and consequently it develops problem solving skills as well as basic skills (Stepien et al., 1993: 340). Problem based learning motivates students to define the problem, search for the concepts and cooperative learning. It improves communication skills, and supports a powerful classroom learning process which uses real-life problems (Duch et al., 2001).PBL requires people work with a group or a team, cope with different situations, improves self learning and self evaluation skills and motivates people to practice these skills (Woods 1996).

Lehtinen (2002) identifies the steps which are required for implementing the PBL as following: a) Clarifying concepts b)defining the problem and listing the concepts which need to be learned c) Brainstorming d) systematic classification d) formulating the learning objectives e) Lectures and self study f) clearing up g) Reporting

Studies showed that PBL is more effective in increasing students' academic achievement, as well as allowing them to work in groups and construct their knowledge through social negotiation compared to traditional teaching methods (Polanco et al., 2004; Sungur et al.,2006; Goodnough, 2003). Problem based learning is highly appropriate for realizing the aims of science education. Problem based learning might be an effective way of promoting science learning, which is highly related to real life and requires students to possess high level of critical thinking skills. In fact, many science educators investigated the effects of PBL in science education (Treagust & Peterson, 1998; Greenwald, 2000; Şenocak, 2005; Wilson, 2005; Kılıç, 2006). The purpose of the present study is to investigate the effectiveness of PBL in 6th grade students' higher order thinking skills such as comprehension, problem solving, and science process skills.

METHOD

The study was designed according to the pretest-posttest with control group model, which is one of the true experimental models. The study was conducted with 6th grade elementary school students. According to Science achievement test that was done before the application, two equal classes were selected. While problem-based learning was implemented in one class by the researcher, the traditional methods were implemented in the other by the teacher.

An achievement test prepared in accordance with objectives of the topic entitled "Static Electricity" in the instructional unit "Electricity Guiding Our Life" in the science and technology course was used as testing tools. These testing tools were administered to the experimental and control groups as pretest and posttest. The data obtained after an application that lasted 6 weeks were analyzed. For analyzing the data, t-test has been used.

Sample

The sample of this study consisted of two separate 6th grade classroom students from an elementary school in city of Konya which is located in Turkey. The two classes had similar socioeconomic backgrounds, similar curriculum implemented and same topics covered in both classes. Experimental group consisted of 31 students and control group consisted of 30 students.

Variables:

Independent variables: Independent variable is the instructional methods. Experimental group utilized problem based learning and control group utilized traditional instruction.

Dependent Variable: Higher order thinking skills

Instruments:

Science Achievement test

In order to collect data for he dependent variable which was investigated in the study, an achievement test was developed, pilot tested and administered. The objectives of the lessons related to the topics in "Static Electricity" which was covered in the" Electricity Guiding Our Life" unit were determined. The objectives or each lesson in the topic "Static

Electricity” were identified at a table to ensure content validity of the achievement test items. In accord with this table, 37 questions were prepared to test the higher order thinking skills of the students. The questions were investigated by science teachers and experts in the area of assessment and evaluation and some revisions were made based on their suggestions.

37-item pilot test was administered to one hundred and twenty 7th grade students. Based on the data, reliability constant (KR-20) of the test and discrimination indices of the each item were computed. The items which have item discrimination index under 0.30 were eliminated form the test. Based on the analyses, final test was consisted of 30 items and the reliability constant was found to be 0.74. The test was consisted of items which were accessing *comprehension* (10), *problem solving* (10) and *science process skills* (10).

Analysis of Data

The statistical techniques used to analyze the data were means, Standard deviations and t-test. The Data were analyzed by using statistical software SPSS.

RESULTS

Pre-test Results

Table 1. Comparison of experimental and control group for difference in comprehension level of learning on pre-test

GROUPS	N	$\bar{X}$	Ss	t	p
Control Group	30	2,97	1,75	1,872	0,066
Experimental Group	31	2,26	1,15		

Table 1 shows that pre-test scores on comprehension part of the test is 2.97, while it is 2.26 for problem based learning group. The t- test result indicates that there is not a significant difference in terms of comprehension at 0.05 significance level.

Table 2. Comparison of experimental and control group for difference in problem solving skills on pre-test

GROUPS	N	$\bar{X}$	Ss	t	p
Control Group	30	2,90	2,02	1,232	0,223
Experimental Group	31	2,32	1,62		

Table 2 shows that the mean score for control group students is 2.90 and 2.32 for experimental group students in the problem solving skills part of the test. t-test result indicates that the difference is not significant at 0.05 level. The result suggests that there is no difference in problem solving abilities of the two group students.

Table 3. Comparison of experimental and control group for difference in science process skills on pre-test

GROUPS	N	$\bar{X}$	Ss	t	p
Control Group	30	2,5	1,46	3,939	0,000
Experimental Group	31	1,13	1,26		

Table 3 shows pre-test scores of students on science process skills. Science process skill scores for traditional instruction group is 2.5 and for problem based instruction group it is 1,13. t-test result shows a significant difference at 0.05 level. Control group students' science process skills were found to be more improved compared to experimental group students.

Post-test Results

Table 4. Comparison of experimental and control group for difference in comprehension level of learning on post-test

GROUPS	N	$\bar{X}$	Ss	t	p
Control Group	30	4,7	2,17	-6,903	0,000
Experimental Group	31	7,87	1,34		

Table 4 shows the comprehension level mean scores of the students in control and experimental groups. Mean scores on the comprehension test is 4.7 and 7.87 for control and experimental group respectively. T-test result indicates that the difference is significant at 0.05 level. It can be said that the problem based learning is more effective on students' comprehension level.

Table 5. Comparison of experimental and control group for difference in problem solving skills on post-test

GROUPS	N	$\bar{X}$	Ss	t	p
Control Group	30	5,87	2,06	-4,567	0,000
Experimental Groups	31	7,81	1,14		

Table 5 shows that problem solving ability mean score of the control group students is 5.87 and for the experimental group it is 7.81. t-test result indicates that the difference is significant at 0.5 level. This result suggest that problem based learning is more effective than traditional instruction in improving problem solving ability.

Table 6: Comparison of experimental and control group for difference in science process skills on post-test

Groups	N	$\bar{X}$	Ss	t	p
Control group	30	4,43	1,28	-13,092	0,000
Experimental group	31	8,19	0,95		

Table 6 shows that the mean score on the science process skills is 4.43 for control group and 8.19 for experimental groups. T-test result indicates that the difference is significant at 0.05 level. The result suggest that problem based learning is more effective than the traditional instruction in improving science process skills.

DISCUSSION AND CONCLUSIONS

The results of this study is summarized and discussed in the following section. Based on the analyses of the data the following findings were obtained.

1) There was not a statistically significant difference in the scores related to comprehension level of the learning skills between the students taught by traditional and problem based learning in the pre-test. Control and experimental groups were equivalent. However, the mean score of the control group was higher than that of experimental group.

2) There were no statistical differences in problem solving skills and the science process skills of the two groups based on the pre-test results. However, the mean score on the science process skills of the control group was higher than the experimental group.

3) There were significant differences in comprehension, problem solving and science process skills of the control and experimental group. The students utilizing problem based learning method had higher scores on comprehension, problem solving and science process skills scores than the control group students. According to the results of the study problem based learning seems to be more effective than the traditional instruction to increase students' cognitive outcomes.

4) A statistically significant difference is found between the mean scores on the problem solving ability and science process skills test of the control and experimental group. The study results revealed that problem based learning might be more effective than the traditional instruction in improving these skills.

Problem-based learning applications resulted in improvements in all level of learning outcomes namely comprehension, problem solving skills and science process skills. In control group, classifications, definitions and rules directly given to the students and their getting used to traditional instruction could be the reason of the increase in their scores. However, the increase in experimental group's score is higher than the control group's score. Experimental group students learn the lesson by scenarios, made connections with the real life problems, used inquiry and investigative activities, and tried to acquire the objectives of the lesson by using higher order thinking skills. As a result these activities their skills in comprehension, science process skills and problem solving skills have increased more than the traditional group students. During the experimental application, problem based learning group students stated the problems with their own words which made them aware of the lesson objectives and resulted in success in all cognitive objectives.

Some researchers stated that traditional instruction is not effective in improving students' performance since it does not cover the higher order thinking skills (Greening, 1998;

Stattenfield & Evans, 1996; Chang, 2001, Yaman, 2003). Students in experimental group had higher scores in problem solving ability part of the post-test could be related to the fact that they learned their lessons by solving problems. In the intervention period they learned the concepts by searching the problem subject, gained the skills during their lessons and their cognitive skills were developed when they were solving the problems. In problem based learning students should analyze nature of the problem and the problem situation truly to be able to solve the problem. Experimental group students tried to solve the problem by brainstorming, and discussing the why and what questions with their group mates. In static electric subject, problem based learning approach enabled students to think broadly and deeply, improved their inquiry skills and consequently improved their problem solving ability.

oblem solving process requires following steps such as identifying the problem, formulizing the problem, generating alternative solutions, and evaluating the results. In problem based learning students identify the problem, identify what they already know, what they need to know, what materials they need, and what they need to do with their team mates cooperatively. Such activities show similarities with the steps of problem solving ability. Fort his reason students become more effective and acquire expertise in problem solving. Other studies (e.g., Banta et al, 2000; Kaasbøll, 1998; Kwan ve Ko, 1999; McDermott et al., 2000; McDonald, 2002; Orrill, 2002; Perrenet, 2000) also reported improved problem solving skills of the students who utilize problem based learning approach. These studies associated the improvement with students' struggle to cope with the difficulties.

On the other hand, science education includes many other complex skills within the science process skills which include observation, identifying the problem, formulating the hypothesis, identifying the research problem, designing the experiment to test the hypothesis, doing the experiment, collecting data and analyzing data, generalize the results. The reason why experimental group students showed more improvement in their science process skill levels might be related to their applying these steps. Problem based learning, by making students active, acquiring them responsibility of their own learning, using inquiry practices, and enable them to find out the relationships between concepts, improved the science process skills level of experimental group students. Actually, every student has these science process skills. However, these skills need to be used to be improved. By improving science process skills, experimental group students' problem solving skills improved as well. They become more able to think critically and make connections with real life problems.

Problem based learning approach requires using many of the science process skills effectively as well as problem solving skills. Activity dimension of the problem based approach contributes to developing and improving skills related to scientific processes.

SUGGESTIONS

1) Problem based learning requires material usage in a large extent. For this reason, science classes and the laboratories should be supplied with the necessary materials and equipment.

2) Problem based learning requires in class and out of class activities. The parents should be informed about PBL is important for the success of the approach.

3) Creating a school atmosphere which is suitable with PBL approach is important for practicing the method. Support from the other disciplines' teachers, school administrators, and science teachers' to the PBL practices is important since it is an interdisciplinary approach. Consciousness about this approach should be developed in school personnel.

THE DEVELOPMENT, IMPLEMENTATION AND EVALUATION OF AN INTENSIVE SYSTEM-WIDE PROFESSIONAL LEARNING PROGRAM FOR PRIMARY SCIENCE TEACHERS

Deborah Corrigan **Richard Gunstone** **Rebecca Cooper**

Centre for Science, Mathematics and Technology Education, Monash University, Australia

deborah.corrigan@education.monash.edu.au

ABSTRACT

An intensive 3 day professional leaning program for primary teachers of science was designed, implemented and evaluated. Design foci included concerns with increasing both teacher confidence in and knowledge of science, recognition and appropriate use of the pedagogical expertise of primary teachers, and 6 specific areas of practice (How students learn science, Teaching for understanding in science, Understanding and teaching the nature of science, Engaging students in contemporary science, Planning the science curriculum, Assessing understanding in science). In the 2-4 week gap between days 2 and 3 of the program participants undertook some form of change in their science classrooms and reported on this to day 3 of the program. A range of forms of evaluation data were collected. Examples are: pre- and post-program on-line surveys, a set of open questions used as part of the learning experiences in day 3, the nature of the change projects undertaken and reported by participants, reflections by those teaching the professional learning program, open-ended evaluation questions given in differing forms to different cohorts in the program. The paper considers these data and the ways the data relate to the design and delivery of the program.

Keywords: *curriculum development, curriculum reform science teaching, science learning, professional learning*

INTRODUCTION

The government of the state of Victoria (Australia), as part of its responsibilities for primary and secondary schooling, has an explicit policy focus on increasing student engagement with science and mathematics and improving learning outcomes in these curriculum areas. Through the Department of Education and Early Childhood Development (DEECD) it also has clear policy directions to provide appropriate resources (including professional learning opportunities) for teachers to pursue these priorities. It is in this broader context of ongoing foci on science education and professional learning that the work to develop, implement and evaluate a system-wide professional learning program for elementary science teachers was contracted to the Science Education Research Group at Monash University. This paper will outline the development and implementation of this program by members of the Monash Science Education Research Group, and then consider the consequences of the program (evaluations of the program) and ways these consequences might relate to aspects of the development and implementation features as well as teachers' responses as a result of the government priorities.

THE DESİGN AND İMPLEMENTATİON OF THE PROGRAM

DEECD defined multiple intentions for this program *Primary Science Matters: Professional Learning in Primary Science.* It required:

- the professional learning program to build teacher capacity to improve student learning outcomes in science,
- the provision of support for primary teachers in implementing the science domain of the current Victorian curriculum guidelines,
- emphasis on the key messages of existing science support materials and in particular an on-line teacher resource *Science Continuum P-10* (http://www.education.vic.gov.au/studentlearning/teachingresources/science/scicontinuum/default.htm) that supports teachers of students ages 5-15, (Corrigan et al. 2009), and a comprehensive set of materials combining science and literacy, *Primary Connections*, see Hackling et al. 2007), and
- consistency with other relevant policy and practice from DEECD such as a set of *Principles of Effective Professional Learning* and a new *E^5 Instructional Model* for conceptualising learning and teaching based on the 5Es model developed by BSCS,
- the building of the educational leadership capacity of primary teachers in the area of science" and address the following areas of teacher practice: How students learn science, Teaching for understanding in science, Understanding and teaching the nature of science, Engaging students in contemporary science, Planning the science curriculum, Assessing understanding in science. In considering building the educational leadership capacity in science through these six ideas the program needed to address these ideas "with reference to a particular science curriculum focus, thus building both pedagogical content knowledge and discipline knowledge of participants."

The program was to include an online resource to support learning during the program and to be of 3 days duration in a 'sandwich' structure of an initial 2 days and a later single day, to allow teacher research and development activity between Days 2 and 3. Implementation of the program was to be in cohorts of up to 20, by regions; there are nine such regions in Victoria.

AN OUTLINE OF THE GROUP RESPONSIBLE FOR THE PROGRAM

The Monash Science Education Research Group (referred to as the Monash group) is a highly experienced team of some twelve science educators of high local, national and international reputation. The group is committed to bridging the gap between theory and practice in the work it undertakes such as in the Science Teaching and Learning (STaL) program to develop the science capability of teachers, both primary and secondary (see Berry and Loughran, 2010; Loughran et al, in press); Loughran and Berry, 2006, 2007, 2008; Berry and Keast, 2009, 2010).

In working with teachers, an important strength of the Monash group is to support these teachers to be researchers. In this way, teachers develop knowledge and skills that will place them in positions to make pedagogical choices based on evidence they have gathered through researching their own practice, the learning environment in their own classrooms and schools, and through monitoring the learning outcomes of their students. This approach to research work places the teacher in the position to make informed choices, based on their own learning, about how to maximize the learning opportunities for their students. In order to achieve such a professional learning experience for teachers a variety of approaches have been adopted. Some examples include:

- providing intensive face-to-face workshops for participants to develop a collegiate group, providing some substantive theoretical bases from which to work, and to collaboratively set some learning goals for research back in their schools (see Corrigan et al, 2008; Cooper, 2008; Keast and Berry, 2008),

- meeting the needs of teachers, while giving them a voice to contribute to the science education research literature and providing teachers access to expertise in discipline knowledge, teacher research capability and sources of innovative practice (see Corrigan and Gunstone, 2009, 2010;Loughran et al, 2009; Berry et al, 2008; Corrigan, 2008; Loughran and Penna, 1999; Loughran et al, 2006; Gunstone et al, 2005; Corrigan and Gunstone, 2007),
- providing opportunities for real change in classroom practice by working with teachers developing innovative and sophisticated practice that build ways of identifying, framing, representing and re-representing such practice as well as the teacher knowledge that lies behind this is a critical expertise. Related to this is our passionate belief in the importance of teacher knowledge and teacher research, not only for the profession, but for the more general field of educational research.
-

The development and implementation of the program

Both the extensive previous experience of the Monash group and strong awareness of a substantive relevant research and development literature pointed to two issues that are consistently fundamental to primary science teaching across contexts (including cultural contexts, and time). Primary teachers often lack confidence to teach science, and often have poor conceptual understandings of the science they are expected teach, particularly for concepts other than biological. Matters of teacher confidence and conceptual understanding were then constant fundamentals that influenced development and implementation throughout the program, and were also of course prominent aspects of the evaluations that were undertaken.

Also fundamental to the design of the program was the emphasis on professional learning, where the expectation was on each participant being part of a buddy pair that would be responsible for undertaking a small action research project back in their own schools betweens Days 2 and 3.

The development process began with a small group meeting to consider broad sequencing of sessions, across the first two days in particular as Day 3 was clearly understood to be about sharing what participants had done as the action research projects in their schools since Day 2, and using these experiences to develop greater understanding of change, planning and support. A sequencing of topics for the two days and a brief summary of focus in each was generated, and used to gain feedback from a wider Monash group. Then, with four sessions per day for the two days, each session was given authors and they developed a first draft of detail. As each session evolved there were meetings to inform and gain critiques with the broader Monash group, with experienced primary teachers who were to be part of the implementation team and with DEECD staff. A substantial number of presenters needed to be used in the delivery of the program so the sessions were prepared in considerable detail.

Each session was presented in final form with the same broad structure: a summary description and list of session activities and suggested broad time allocation; a statement of intended session outcomes; a list of required resources and materials; and then the detail of each activity. The activity detail indicated what both presenters and participants were intended to be doing, where and how the provided resources were intended to be used, suggestions of links and/or possible difficulties to expect, links to other resources, and a summary indication of what links might be emphasized to (a) the relevant curriculum guidelines, (b) the resources *Science Continuum P-10* and *Primary Connections*, (c) the E^5 instructional model and (d) assessment matters. The Day 3 session detail was developed after a number of the Day 1 and 2 programs had been conducted, so as to reflect the substance of those experiences.

Pairs of presenters implemented each program, one from the Monash group and one an experienced primary science teacher, with, the same pair conducting all three days for each cohort. Individual presenters worked with between one and four cohorts. For each cohort, presenters were provided with a suitcase containing all materials required, and a memory stick with electronic copies of all materials including powerpoints and some video materials.

Recruitment of participants was the responsibility of DEECD. Pairs of participants from one school were strongly encouraged due to the nature of the professional learning participants were to engage in. As participants enrolled in the program they were asked to complete an on-line pre-program survey. This was an important beginning to the program as presenters were committed to learning about the cohorts they were to work with and tailor the program to met the needs and experience levels of participants. On completion of Day 3 all were asked to complete a very similar post-program on-line survey. The professional learning program was undertaken across the nine regions of Victoria during March – June 2009. Details of this program can be accessed at http://www.education.vic.gov.au/studentlearning/teachingresources/science/priscimatters/default.htm.

The consequences of the program

There are a number of forms of data of relevance to informing us of the consequences of the program. Examples include the frequency and forms of activity brought back to each cohort for the Day 3 sessions, some extensive written reflections on the program and the Day 3 consequences by individual presenters, and open-ended evaluation questionnaires administered to cohorts at individual level by regional DEECD staff. All these will be addressed. The focus in this proposal is on three data sources that are most comprehensive and more amenable to summary. The first form of data are the results of a pre- and post-program on-line questionnaire designed to provide some insights into participants' perceptions on the teaching and learning of science, their own levels of understanding in science and their expertise to teach science, both before and after the program. The second set of data are representations of the reflections that were collected throughout the program, with particular attention to participants views on science, while the final data set are responses to a set of six questions that were used with all cohorts as part of the learning experiences on Day 3 of the program.

Pre-program and post-program on-line surveys

The pre- and post survey instruments were similar in many respects, particularly with regard to the six areas of focus for the program, namely How students learn, Teaching for understanding in science, Understanding and teaching the nature of science, Engaging students in contemporary science, Planning the science curriculum and Assessing understanding in science. In addition, confidence in both the primary teachers' understanding of science concepts across a range of year levels and their capacity to act as a leader in science within their school were also a focus of these instruments. They also differed in some important aspects as the pre-survey also focussed on gaining clarity for the presenters around who are the cohort and what background and experience do they bring to the program. This highlights a strong constructivist perspective underpinning this program. The post survey focused more on reflective elements of how participants responded to the program. This highlights a strong emphasis on a formal reflection process as a mechanism for articulating your learning that was also a fundamental underpinning of the program.

Of the more than 200 participants who attended the program from all nine regions, 196 completed the online pre-survey. The majority (76%) were classroom teachers, with 77% of participants being female. Approximately 30% of participants had studied science to Year 12, with 28% having only studied science to Year 10. A smaller percentage had studied science at a tertiary level (1 year – 7%, 2 years – 4%, 3 years – 11% and 4 years – 13%). Many

(33%) participants had more than 21 years teaching experience, with 25% having between 2 and 5 years experience, 19% between 6 and 10 years and 17% having between 11 and 20 years. There were 6% of participants in their first year of teaching.

The participants' pre and post program survey results showed some significant shifts. For example participants identified the Science Continuum P-10, Primary Connections, Victorian Curriculum Guidelines and the E^5 as resources they would make much greater use of to teach science in the future. The post program evaluation data appears to strongly support that the program was successful in meeting its intended aims. As indicated in Figure 1, the program appeared to address the 6 areas indentified in the program design.

Figure 1 gives the overall rating average where the maximum rating is 4.0. With no area rating less than 3.0, it appears from participants' responses that all six areas have been addressed, particularly engaging students in contemporary science. The ratings are based on responses ranging from not addressed, addressed to some extent, addressed well, to addressed very well.

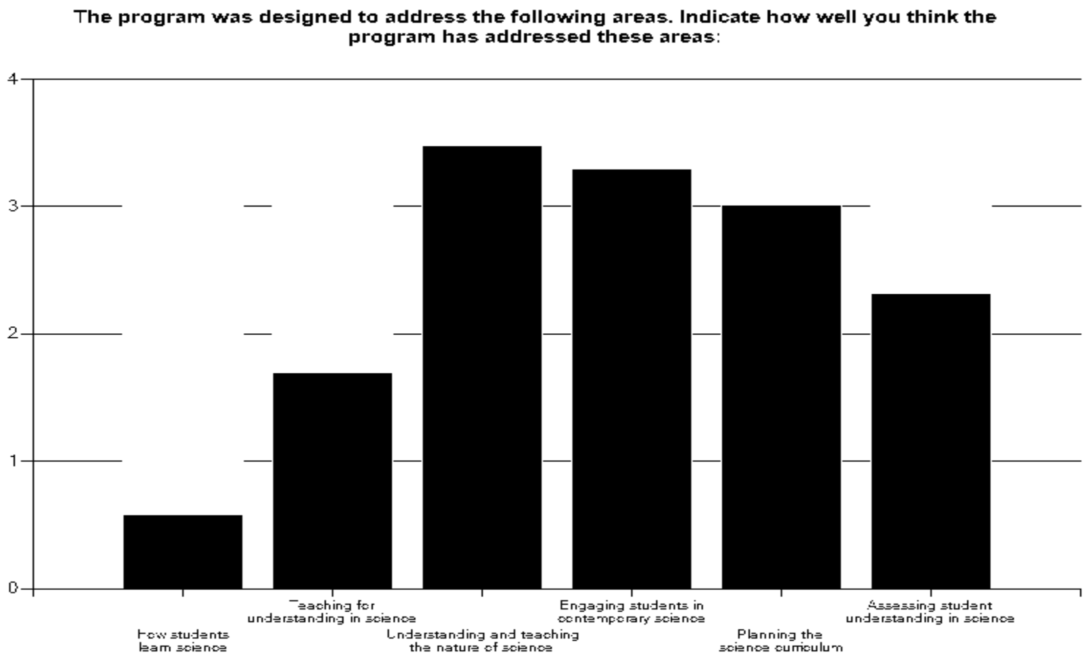

Figure 1: How well did the program identify the six areas.

In addition, participants were asked how confident do they feel in providing some leadership in professional learning in science as a result of this program. The responses are represented below in Figure 2.

Again the maximum rating average possible is 4.0. Most teachers felt quite confident to lead some professional learning in science as a result of this program with another teacher or with a small group of teachers. This response indicates the importance of participants having another member from their school participating in the same program, sharing similar learning experiences if they are to feel more confident to do similar things back in their own school. It is pleasing that there are quite positive responses indicating some confidence to undertake the leadership in such professional learning in science in a variety of ways in their schools. Indeed some participants actually undertook some professional learning in science in their schools as their chosen 'mini' action research project.

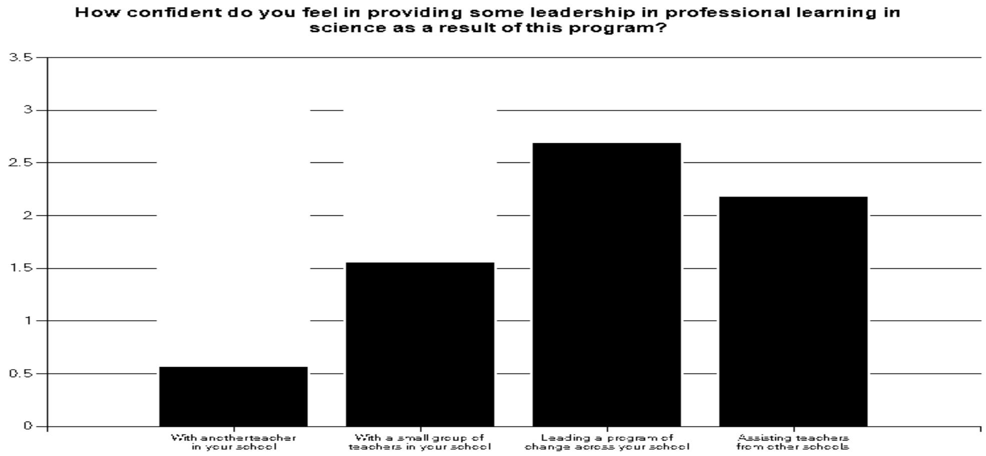

Figure 2: Confidence in providing some leadership in science.

Participants have also indicated increased confidence in their content knowledge after the program. The comparison can be made between the Figure 3 below. This figure indicates that participant confidence had increased in all content areas, with the exception of perhaps the particle theory, although even the average rating for this has also increased from 0.50 to 0.97. Again this figure indicates average ratings where the maximum score is 4.0.

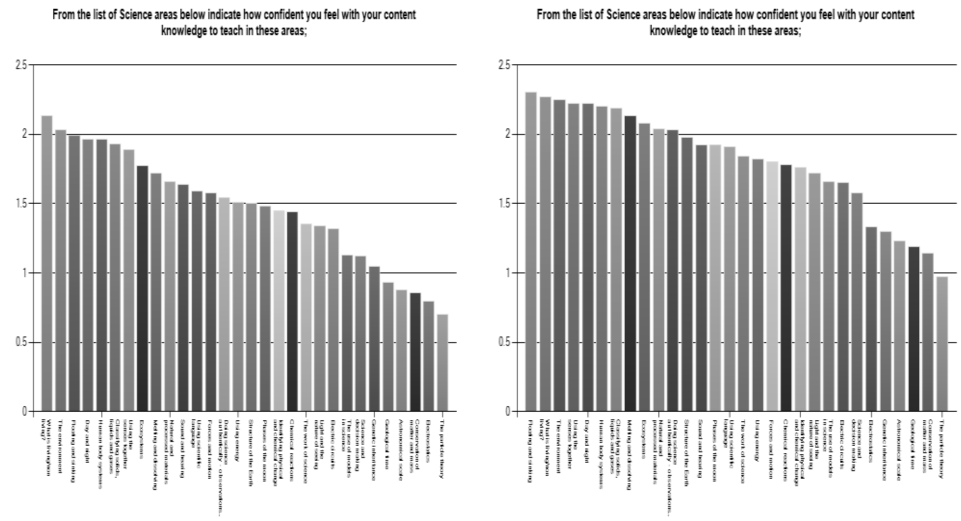

Figure 3: Confidence in their own knowledge of particular science content areas pre-program (on the left) and post program (on the right)

Legend for Figure 3: The order of content areas from left to right are:
Floating and sinking
What is living/ non living
The environment
Using the senses together
Day and night
Human body systems
Classifying solids, liquids and gases
Melting and dissolving
Ecosystems
Natural and processed materials
Doing science authentically – observation
Structure of the Earth
Sound and hearing
Phases of the moon
Using scientific language
The work of science
Using energy
Chemical reactions
Identifying physical and chemical change
Light and the nature of seeing
The use of models in science
Electric circuits
Science and decision-making
Electrostatics
Genetic inheritance
Astronomical scale
Geological time
Conservation of matter and mass
The particle theory

The maximum score possible in this confidence scale is 4.0 where this represents very confident. Other alternatives in this scale included quite confident, a little bit confident and not confident at all.

The increase in confidence in this range of content knowledge is important from a number of perspectives. Not only does it generally indicate increased confidence as a result of the program, but the range of topics is content knowledge that spans the P-10 (ages 5-15) range and not just content primary teachers would be expected to encounter in the P-6 range, the years of primary school education in Victoria. The more abstract ideas of Astronomical Scale, Geological time, Conservation of Matter and Mass and The Particle

Model, while still presenting some challenges for teachers in terms of their confidence to each in these areas, have shown some increase to the category “a little but confident”.

Summary of reflections from the program.

Throughout the program there were a number of opportunities for participants to reflect on their learning. Many of these tasks were structured in a variety of ways in order to expand participants’ knowledge of possible reflective strategies. What is presented here however, is a summary of those reflection with particular reference to the participants’ understanding of science. All reflections are from different participants in the program.

> Investigating values linked to science. I was interested in determining if the personal statements [about science] were true of false. There were some statements that challenged me to think about my understandings of science in schools and our approach to the delivery of the science curriculum.
>
> Many science topics may not be as scary to teach as I thought. Many science ideas can be taught from one topic.
>
> Teachers and students can ask and solve questions together, without actually knowing all the answers.
>
> Science is everywhere. A great question is “What science is in that?”
>
> This PD has given me a different perspective about the way science is taught in school and has made me reflect on the way I teach science to my students. (I currently teach what I know or what I am comfortable with… when I challenge my students to do the opposite).
>
> Up until now I viewed my role as a science teacher as the medium through which students learn lots of ‘facts’ – or ‘get to know things’. Now I’ve changed this view…[and] think it is my role to encourage students to be open to the idea that thoughts and ideas change and that we need to be open to this, basing it on justifications.
>
> If we say we value challenging student ideas about science then what are the issues that arise for teaching science?... With more confidence in my own ability I am now willing to let go of the reins and give them to the students more.

Not all comments were positive.

> [I was] scared about the student reactions to the inquiry approach when they expect teacher led lessons or send out negative vibes.
>
> I feel less confident in leading Science than before this session.

And some time after the professional learning program concluded, one of the comments was:

> I just wanted to report back…we did our first science session this morning. The experiment was a complete disaster…apart from this the lesson went really, really well. I’m in love with KWL…because we discussed the answers and there were heaps of great questions and it was generally a really engaged and high-quality discussion. Personally I’m spending a bit of time getting myself organised and setting some goals (motivated by the PD). I’m feeling much better about my teaching and also much more enthusiastic about things. Thank you , science PD! You’ve put me back on track!

Responses to open-ended questions

Much of the Day 3 program was structured around sharing and reflecting on the activities participants had undertaken in the two to four weeks that had elapsed since Day 2. Where possible this was done in pairs from the same school, in part to further encourage the development of ‘school buddies’ for mutual and subsequent support for further professional growth.

The first half of Day 3 was substantially devoted to participants, in pairs, preparing presentations about what they had tried by way of different approaches to teaching science since Day 2, and then making these presentations to the whole cohort. Six questions were given to participants to scaffold the presentations ('what was done? or learnt?'; 'why this?'; 'feelings, worries, uncertainties before doing this?'; 'what was the effect on you? your students?'; 'what implications has this for your teaching?'; 'what do you plan for the future?').

Before the presentations began, each member of the cohort was given one of these six focus questions and asked to identify common themes across presentations relevant to the question. Each individual made notes of the themes they identified. All those with the same focus question then prepared a short summary of their notes to feed back to the whole cohort. The individual notes were collected and form part of the evaluation data reported in this paper.

Some examples of themes identified, across all cohorts:

1. What was done or learnt from this experience?
   - A wide range of teaching strategies were used in the program and were specifically mentioned as ways to probe students' prior views on a topic.
   - There is an increased awareness of resources (*Science Continuum P-10* and *Primary Connections*), and how to use them.
   - Participants reported an increased confidence in and flexibility when teaching science. They commented that they (the teachers) must engage the children and ensure that they are involved in the teaching and learning.
2. Why this?
   - The reflective tools were easy to take back and incorporate immediately into class…These tools made the teacher and their students think more carefully about what they were doing and why.
   - The resources demonstrated helped to draw links between science and other curriculum areas e.g. literacy.
   - Teachers we interested to involve other teachers at their school and make science more meaningful
6. What do you plan for the future?
   - Participants would plan units of work using the resources presented e.g. *Primary Connections*.
   - Participants identified the need to incorporate the tools for reflection into their teaching more often.
   - Participants felt that you could teach science without having to be an expert.
   - Participants wanted to give greater recognition of student prior knowledge and awareness of science in the students' world**.**

Links between these consequences and development/ implementation approaches

So far, one issue stands out as overwhelmingly important for the generally very positive consequences of the program. That is the very clear and strong concern with engaging the participating teachers in active and meaningful learning during the program – a clear concern with how the program was taught, as well as what issues were addressed. Of specific importance has been the way the program has made legitimate uses of the pedagogical approaches argued during the program to be important for student learning, and thus a clear demonstration that those things argued by the program presenters to be of significance for learning were indeed valued sufficiently that these were used by those presenters.

In terms of future plans for this professional learning program, there is a commitment from DEECD to continue this program in 2010, however with a new set of participants, rather than focusing on the further development of those who have already participated. This strategy is focused on building the capacity of primary teachers in teaching science across the state, rather than developing the capacity of a limited number of primary teachers.

SCIENCE FOR SUSTAINABILITY: CONTEXTUALISING PROBLEM BASED LEARNING

Roger Cutting

University of Plymouth
rcutting@plymouth.ac.uk

Orla Kelly

University of Plymouth
okelly@plymouth.ac.uk

ABSTRACT

In the last decade a number of low environmental impact communities have been established across the UK. These communities are characterised by self-built dwellings, self-reliance and an attempt to live at 'one world' levels of consumption.
In the last two years a module delivered to science education students at the University of Plymouth (UK) have been based on problem-based learning. These have been laboratory based and have utilised role-play and/or short narrative scenarios. The problems have therefore been 'provided' and have been fictitious.

Following evaluation, it was decided to include real problems and low impact communities were identified as a perfect place to find such problems. In early 2010 students visited and worked with local low impact communities, identifying problems that such sustainable living provides and began to research and eventually suggest potential outcomes. The science-based problems that formed the basis of this part of the module are therefore appropriately contextualised and the outcomes (including negatives) have direct application.
The students unanimously reported that they felt that they learned more about the issues relating to sustainability and science and that the context of real tasks was a qualitative improvement in the problem-based approach. However, they remained unconfident about using sustainability-based science in their own teaching.

Keywords: *Sustainability science, Problem based learning, Low impact communities, Science teaching.*

1. INTRODUCTION

While the issue of Global Warming has taken centre stage recently with the UN Climate Change Conference in Copenhagen (2009) the degradation of the environment seemingly continues. Every indicator of global environmental health seems, at present to be moving towards a more critical position (Steffen, W. et al (2004) p336). Finding our way forward and formulating strategies to ameliorate these impacts will undoubtedly be the great challenge and enterprise of the 21st century and one that will require a generation equipped with the appropriate skills, intellectual resources and creative invention to embark upon this endeavour. As educators and teachers of this future generation we seem to have accepted the responsibility for such an empowerment and we have not been slow to respond. In the last three decades there has undoubtedly been a robust response in the promotion of environmental education and education for sustainability both of which have begun to influence curricula in many countries and at many academic levels (Scott, 2009). Indeed, we now find ourselves at the mid way point in the UN Decade for Education for Sustainability.

In the field of science we have seen the advent and development of 'Sustainability Science' as not only a field of research, but even as a new research paradigm (Clark and Dickson, 2003). We have seen issues surrounding sustainability and the environment begin to be included in teaching programmes and their has been a distinct shift away from education merely about environment towards an education for the environment, one that promotes its conservation. (Reid and Scott, 2006)

However, whether these developments have had sufficient impact on curricula is questionable. In the United Kingdom (UK) significant progress has been made at elementary levels (Peacock, 2004) but a brief examination of the Science syllabuses for 16+ examinations in the UK shows little that directly relates to education for sustainability (EfS). The 18+ syllabuses (GCE Advanced Level - the primary matriculation qualification to UK universities) for Physics and Chemistry have no content that relates to EfS. Students may arrive at undergraduate level study with only a rudimentary understanding of sustainability issues generally and little comprehension of the contribution of science to the sustainability agenda.

Combine this with the growing criticism levelled at traditional 'expository' approaches to science teaching (Carillo, Lee and Rickey (2005), Johnstone and Al-Shuaili (2001), Hofstein and Lunetta (2004), McDonnell, O'Conner and Seery (2007)) and we fall someway short of the dynamic, engaging, cross-curricula approaches that are seen as necessary to deliver a sustainability science (Komiyama and Takeuchi, 2006).

New methods and approaches of science teaching need to be developed if we, as a generation of educationists are to prepare our students to meet the environmental challenges of the future. We need methods that promote creative and innovative thinking, encourage criticality and that recognise, through contextualisation, the limitations of science methodologies. In short, methods of science teaching that simply promote good science practice.

Problem Based Learning and the Science of Sustainability

In the last decade, PBL has become "one of the most popular curricula innovations in higher education" (Tan, 2004:p170). It requires a shift in focus from the traditional, didactic method of teaching, where the lecturer is the expert, transmitting knowledge to the students with coverage of content the focus, to a student-centred style where students are problem solvers, the lecturer is in a coaching or facilitating role, and the problem is the focus of the learning from which content is derived. (Tan, 2004). The reasons for the effectiveness of such approaches are elusive, but may relate to different learning styles. PBL encourages what Petty (2004) has described as 'deep learning'; a constructivist approach where learning is achieved by adapting and building on prior knowledge, skills and concepts thereby allowing the learner to seek meaning for themselves and not the meaning as constructed by their teacher. More recently, PBL is currently receiving much attention in physics, chemistry and biology education. (Freitas, Jiménez, & Mellado 2004; Ibáñez-Orcajo & Martínez-Aznar 2007; Kelly & Finlayson 2007; Lee 2007) The benefits of this problem-based approach, particularly in science, are summarised well by Tan (2004):

- Bridges the gap between theory and practice
- Enables development of real world competencies – which are strongly linked with the scientific method

- Promotes a constructivist approach to learning, which is extensively practiced in science teaching (Driver 1983).

Collaborative group work is a significant element of the approach. Exley and Dennick (2004) describe how, during group activities, learners can be provoked into thinking deeply by questions from their peers and teachers that challenge students and encourage them to take ownership of their own learning and can support a constructivist approach to learning.

Given the proposed benefits of PBL and the limitations of the expository model of practical work, problem-based approaches to science teaching are proposed as a possible approach to the teaching of sustainability science.

Low Impact Communities, Problem Based Learning and Sustainability Science

In 2007, a module entitled 'Foundations of Science' was offered to first year undergraduate science specialists enrolled on an Initial Teacher Training programme at the University of Plymouth. This particular module had gone through a review process that had led to it being redesigned to be delivered entirely through a PBL approach. The module was monitored across the year and the student's experiences were reviewed at strategic points (Kelly and Cutting, 2008). Generally, the module proved successful, but it was felt that the problems that the students are asked to address became known to the staff team and in the following year lost something of their originality. As a result, it was decided to review part of the module (in the first instance) and secondly, to address problems relating to the science of sustainable living.

In the last decade a number of low environmental impact communities have been established within the British countryside (Cook, 2008). They are singular examples of people in the industrialised world attempting to live very near 'One World' standard of resource use (WWF, 2006; Knight, 2007). This means that they have the level of resource demand that could be sustained by the entire planetary population, and that they are consequently the nearest examples we have in the U.K. of "sustainable living". They involve groups of people who are living in self-built dwellings unconnected to mains water, drainage, sewerage, gas or electricity. They combine a strong ethos of self-reliance, which ensures that their needs are largely provided from a small and predominantly local resource base thereby causing minimal disruption to the environment. Recent work describes low impact communities (LIC's) and variously considers their social, environmental and economic merits (Pickerill & Maxey, 2009; Laughton, 2008; Rosen, 2008) and this study is based on the work of LIC's that have been established in the south west of England.

LIC's present intriguing opportunities within the context of sustainable living for problem based learning especially in relation to the application of practical everyday science. These increasingly popular 'sustainable community' initiatives are populated by young people who often, at their own admission, have no specific skills relating to sustainable living and are therefore themselves on a very steep learning curve. The problems they face include building energy efficiency into structures and shelters, sustainable food production and storage, soil husbandry, power production (in terms of heat and electricity) as well as water supply and waste treatment and discharge. All of these problems are significant in relation to minimising the environmental impact of these communities and have still yet to be resolved in some sites. Providing solutions and making improvements will necessarily involve the practical application of science. The potential for the use of these challenges as means of contextualising PBL in science was recognised by the staff team and hence formed the basis for the second part of the Foundations of Science module. and provided research-based problems for the Year 1 Foundations of Science module.

More than merely land occupations, these LIC's represent a realistic attempt to live sustainably yet in the 21st century. However, they also provide significant scope to extend the student experience of sustainability beyond the theoretical confines and allow them to experience first hand the practical problems and issues of low impact living.

The Project

This took place with a group of 17 students in early 2010. It involved students who were on a four-year, undergraduate initial teacher training programme, with a specialism in science education and training to teach primary school age children. The project occupied 12 hours (excluding group preparation) within a 50 hour taught module. The first part of the module had already introduced the students to PBL through a series of varied science based problems (Kelly and Cutting, 2008).

The first part of the revised element involved two visits to so called Low Impact Communities in the South West peninsula of southern England. Before these visits the students were asked to concentrate on the science aspects of sustainable living and an essential aspect of the methodology was to encourage students to explore their own ideas about the topic and the associated pedagogy in collaboration with their peers, and with the tutor acting as facilitator. Through this process it was intended that they should refine their ideas on science and sustainable living and begin to reflect and evaluate their own potential pedagogical strategies as future science specialists.

The students visited the Steward Wood, Woodland Community, near Moretonhampstead, Devon, UK. (Steward community woodland 2010) This is a community of 18 adults and 5 children. During the visit the students looked particularly at the science aspects of such living with particular emphasis on power, food production and soil husbandry as well as the nature of the construction of dwellings and the treatment of waste products.

The following week the students visited the Forest Garden Project and the Permaculture gardens at Schumacher College, Dartington, Totnes, UK. (Schumacher College 2010) Here they were encouraged to focus on the application of ecological principles relating to these alternative agricultural approaches to food production.

Following the visits and a debrief/review the PBL element of the course was reintroduced.

The students were then divided into groups and asked to investigate the application of their experiences acquired during the visits. The cohort was asked to research and present their findings on different aspects relating to identified practical science problems related to low impact living. A limit of £3000 was set to any suggested schemes. Their research findings were then presented through the production of academic posters and by short presentations.

Finally, the students were asked to critically evaluate their own learning and the potential that LIC's and sustainability science provided for a future basis for their own science teaching.

Research Questions

A number of research questions were identified prior to the delivery of this unit and they included:

1. How do the students perceive the world of the future and what is the present day contribution of science teaching?
2. What, if any, is the impact on student's views of sustainability having visited the communities?
3. What, if any, is the impact on students views of the nature and application of science related to the sustainability having visited communities?
4. What is the educational value of such sites in the promotion of Education for Sustainability?
5. Does the use of genuine issues relating to sustainable living better contextualise a problem based learning approach?

3. METHODOLOGY

The following methods were carried out. The numbers correspond to the research questions.

Research Question 1

Discussion (both class based and on-line) took place in small groups on a number of questions, including;

Will science save the world?
What will the world look like in 30 years?
How will Global Warming affect you?
Will you enjoy better, worse, similar living standards compared to those of your parents?
How will the growing global population be fed?
Should the science of sustainability be a compulsory part of the science curriculum?

Each group reported their views and a wider debate took place and was audio-recorded.

Research Question 2

Prior to the first visit to an LIC the students were asked to draw a picture, or a diagrammatical representation, of the major components of a sustainable community. A content analysis was then carried out on these. The students also completed a two-part questionnaire, which explored their own ideas about sustainability. Part one was filled out prior to the first visit to a LIC and dealt with their expectations. Part two was completed after the visit and concerned how their expectations had matched their experiences.

Research Question 3, 4 & 5

A focus group debate about low impact living and science was carried out after the visits. The discussion was audio-recorded and analysed using Nvivo 8 software. Students were also asked to keep a reflective diary.

4. RESULTS

Research Question 1

In relation to the first research question the student responses given during the discussion are summarized as follows;

1. All students in the cohort expressed the view that 'technology' would provide the answers to global problems.

2. Many felt optimistic about the future and held the view that the world in 30 years time would be similar to today – but based on 'substitute' resources (e.g. Hydrogen for oil, nuclear for fossil fuels).
3. Most saw Global Warming as an issue affecting the Developing World and not of great concern to Developed World.
4. All students in the cohort thought that they would enjoy the same or better living standards than their parent's generation.
5. All saw future technologies as the way in which the world's population could be fed.
6. While many saw sustainability as important, most did not see it as an essential component of the school science curriculum.

Research Question 2

The picture/diagrammatic representations provided an intriguing insight into their initial ideas of low impact communities.

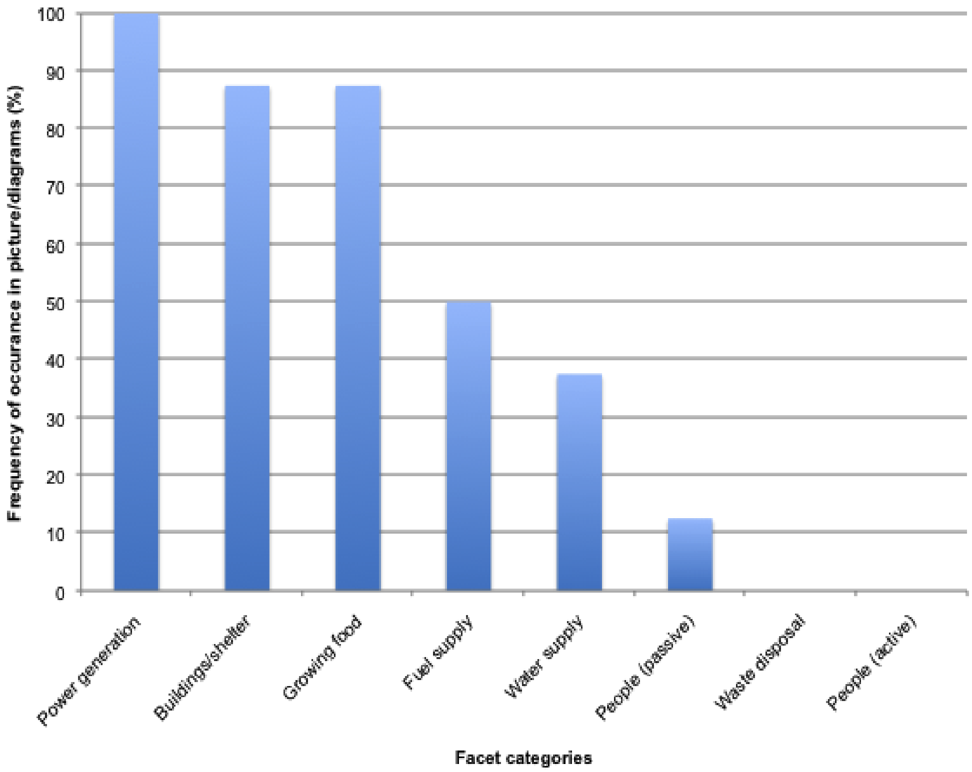

Figure 1. The primary facets included in student's pictorial or diagrammatical representations of the major components of sustainable living.

Figure 1 shows the percentage frequency of identified facets appearing in the pictorial and diagrammatic representations. The picture analysis showed that the most commonly drawn components of LIC's were those aspects that were involved in production. Electrical production (be it through wind generators or solar panels) featured in some way in all of the pictures produced, as did food production and dwellings. Intriguingly no students drew or made representation of toilets, waste treatment and energy efficiency or food storage. Furthermore, no representation of the people in the communities was made (beyond the decorative). The major components concerned the ways in which power, food and shelter could be provided simply in alternative ways.

The pre-visit questionnaire recorded that most students expressed some degree of trepidation at the prospect of the visit although it was also seen as potentially intriguing and interesting. There was a common sense that these community members would be living a very basic, almost pre-industrial life-style with high levels of self-sufficiency, based on low-level technologies.

The post visit answers contrasted both with the expectations of the cohort prior to these visits and to the pictures that had initially been produced. Nearly all students reported a better understanding of the relationship between low impact living and sustainability. They had generally expected the communities to be self-sufficient and generally eschewing modern technology. The cohort reported a much better understanding of the issues related to sustainable food production, not only related to soil husbandry and organic produce, but also the primary limitation of storage (a point few had ever considered).

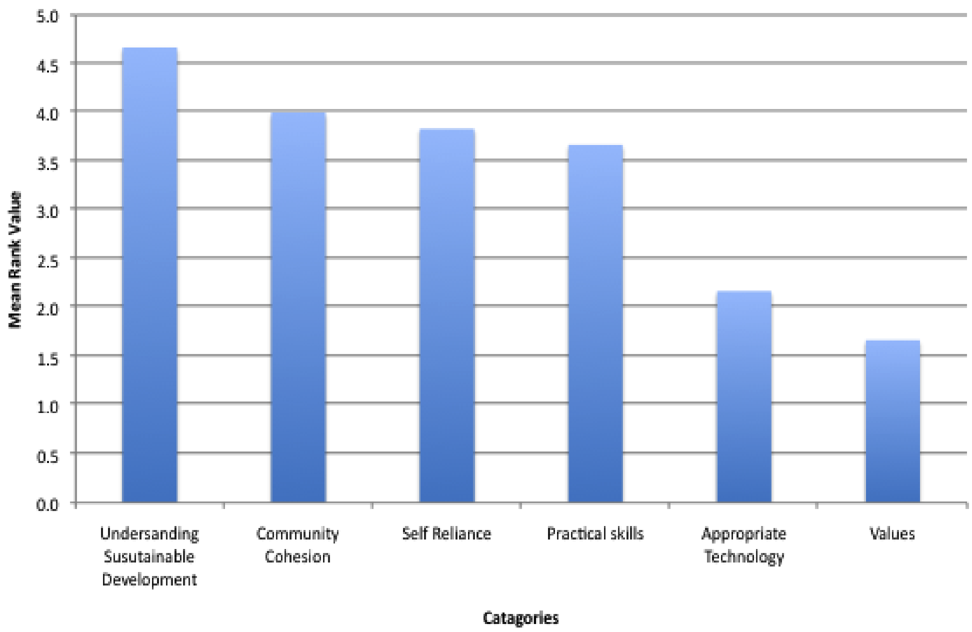

Figure 2. The mean rank scores for post-visit feedback questionnaire asking students to rank what they saw as the most important aspects of sustainable living.

Figure 2 shows the rank scores for what the students saw as the most important aspects of LIC's after the visit. These were 'Understanding Sustainable Development' and 'Community Cohesion'. During the post visit focus group discussion the students expressed the views that 'community was more important than sustainability' and that they had come to appreciate the importance of human relationships in community living.

When asked the question "What is the greatest obstacle to you joining such a community?" the answer, nearly universally was issues relating to sanitation and hygiene. Interestingly, toilets and waste treatment had not been considered prior to the visits.

Research Question 3

During the focus group discussion it became apparent that the students had never thought of sustainability science as a mechanism for the delivery of elementary science components of the National Curriculum. Indeed, most of the students had never covered any topic relating to sustainability or sustainable living in their pre-university science courses. There was a general agreement that they had drawn wind generators and solar panels on their pictorial representations of sustainable communities, but they did not know how much power a wind generator could produce and none knew how a photovoltaic cell produced electricity.

There was some concern that environmental science may be too complicated, or too political a subject to form the basis for general science teaching and some felt that while science could play a role in the promotion of sustainability that there was a certain amount of 'environmental wearyness' related to environmental issues. All students in the cohort however thought teaching science through environmental and/or sustainability issues was worthwhile and that teachers should at least try to apply science more to such issues.

Research Question 4

The students unanimously agreed that they had learnt from the visits, the discussion session and the problem based approach. However, the students reported that while they had learnt about a number of issues relating to sustainable living, that both their personal behaviours had not changed and that their approach to teaching science would also probably remain unchanged. Most agreed that they would take children to the sites, but generally felt that such sites were limited in terms of primary level science education, preferring more conventional and mainstream sustainability events and/or exhibitions. They did however, see LIC's as interesting social experiments and while they were very aware of some of the contradictions of this lifestyle, they thought them worthwhile.

Research Question 5

In relation to the PBL science assignment that concluded the unit, the students unanimously agreed that a 'real' problem or task (as opposed to a fictitious issue) provided the task with context and depth. Students reported taking the problem very seriously in terms of researching the science behind the suggested building improvements and that not only were their decisions confined by a budget, but that improvements and resulting savings were minimal compared to the expenditure. The problem not only promoted group learning but also provided a context for decision-making processes and real limits to what the application of sustainability science could provide. One intriguing comment from the focus group was that they found information about alternative power and heating schemes was fairly freely available and the technology was well advanced and obtainable within the budget. However, the technologies related to waste treatment are far more elusive, expensive and on occasion inappropriate. Several students related this to their drawn pictorial representations of sustainable communities, in that images of sustainability often include technologies to produce power (or reduce its use) that may be inappropriate in terms of output and costs.

All students in the cohort affirmed that they had learnt from the problem and had come to appreciate that the science of low impact living is often overlooked in favour of large, top down 'high tech' science approaches.

5. CONCLUSIONS

Education for Sustainability has a vital role in educating for the future. However, in Science teaching we perhaps encourage students to look to science to solve planetary scale problems. Usually, the magnitude of such problems and the complexity of the scientific response can seem abstracted and beyond the experience (and understanding) of many. Applying science at the level of a sustainable community may have the potential to promote low level practical science as a means of providing sustainable solutions to sustainability problems and provide a context and role for science to be very much part of practical local solutions, rather than a perceived cause of global problems.

The students involved in this module initially looked for large-scale solutions, replacing one fuel with another and suggesting the new technologies of genetics and gene manipulation as a means of increasing food production. They approached global problems from the viewpoint of maintaining (and increasing) production 'simply' through alternative means.

By working on low level technology projects (such as environmentally benign sewage treatment, investigating carbon neutral methods of food storage, evaluating the effectiveness of small scale production of electricity from hydro or wind) the students apply their science knowledge, but in a context of costs, complexity, site suitability, maintenance etc.

PBL has been shown to be an effective tool in increasing student's confidence in scientific methods and in promoting understanding of science concepts and principles.(Kelly and Cutting 2008) However, when applied to real problems it becomes not only a teaching methodology that promotes understanding, but one that also encourages engagement with people. The students not only model the experience of science research, but also are actively involved in its application.

The student's attitudes to the science of sustainability were undoubtedly affected by this use of PBL, but although they could see the relevance of the material they were not enthusiastic about using it as an approach in their own future teaching. This is a generation of future teachers that have themselves been educated throughout the UN Decade of Education for Sustainability, a generation that have grown up with environmental education. They appreciated the importance of sustainability and agreed that it should be part of a curriculum, even part of a science curriculum, however, there was a sense that sustainability issues would be best addressed elsewhere and their understanding of the science of sustainability was generally poor. Therefore, as educators we need to challenge policy makers and influence curriculum guidance to ensure sustainability is included across all ages and ranges within the compulsory education sector. The need for a discussion and debate about the role and place of education for sustainability in our compulsory curricula is suggested as an implication from this research.

However, the application of science to real problems related to sustainability at least allowed them to see the problems and solutions in a context that is generally one of constraints. On some occasions those constraints will be physical (insufficient discharge from a stream, not deep enough soil for a heat pump) at others economic, but the importance of such problems is that it places science at the heart of a community of people. Decisions, solutions and compromises to the localised problems of sustainability are made at a community level.

A problem for science teaching is that science is often seen as the cause of global scale problems, and a problem for science teachers is that they seldom have the experience, knowledge and familiarity of the science of sustainability to effectively address these issues, beyond suggesting alternative technologies that they know little about. Lack of robust knowledge, and a failure to appreciate the context, constraints and impacts of suggested solutions will merely result in the failure of science to provide any solutions. The science of sustainability, like any other branch of science requires students (and especially student teachers) to be both confident in their scientific approach and rigorously critical of their outcomes. However, through community-based problems, students can see the limitations to technological solutions as well as experiencing a decision-making process. At the community level science relates more openly to people, its application becomes democratic and ethical. It can become less technocentric and more outward looking.

Using PBL in relation to the science of sustainable living does not promote a new science. It does however promote good science, a science of both rigour and application. It is through such approaches that we can hope to provide teachers and students of the future with the confidence and assuredness that will be required to face the environmental crisis. Our legacy must not be the problems, but the rather the provision of skills and approaches that provide solutions.

ABSTRACT

A new course called Physics and nature was introduced for the first year students of physics education. Ten different topics, relevant in the present research problems and motivated by the everyday life experiences were adapted to the teaching units at the conceptual level requiring very limited pre-knowledge of physics. The topics were studied through a combination of lectures, laboratory work and seminars.

In this contribution we give the aims of the course, we briefly present the topics (teaching units) and show few excerpts from its realization. We present the analysis of the student assessment carried out before and after the course.

Keywords: *nature, physics, physics education, motivation, in-service training, context based approach.*

INTRODUCTION

The recent implementation of the Bologna programs into the university studies in Slovenia allowed for introduction of new courses and topics. The usual trend was shortening of the courses and depletion of the previously thought topics. But in some rare cases courses that are obligatory although having only the informative message were possible to be introduced. In this contribution we present an example of such an experience: the introduction of a new course Physics and Nature, its structure, the topics taught, and the evaluation of the impact on the knowledge obtained by the students.

The Faculty of Education at University of Ljubljana offers double major university study programs for future teachers in the obligatory lower secondary school, which is similar as the junior high school in some countries. Students elect the combination of two study fields. Due to the organizational reasons the possibilities are limited and defined in advance (Table 1, above diagonal). Within the double major teacher's study program students can study a combination of the two out of the following fields: biology, chemistry, computer science, home economics, mathematics, physics or technology. The program was constructed to allow for all combinations (except the combination of biology with mathematics or computer sciences, which is not allowed by the explicit request of the biologists), as seen in Table 1 below the diagonal.

The Slovenian needs for the double major teachers are approximately 30-40 graduates per year for combinations with mathematics, while approximately 15-20 graduates per year are needed in the combinations of other fields. These low numbers pose additional organizational problems, as students at different combinations have to merge during the lectures of the same course. For example, all students of physics in combinations with chemistry, computer science, mathematics and technology attend a single lecture of physics and the schedule has to be organized in such a way that the four groups have the same cross section of available time for these lectures. Therefore it was decided that the double major program is organized only for the most popular combinations of two study fields, as seen in Table 1, above the diagonal.

Table 1. Possible enrolment combinations for the double major studies. The combinations that are possible to enroll are presented above the diagonal. The combinations that are allowed by the program are marked below the diagonal.

	Biology	Chemistry	Computer science	Home economics	Mathematics	Physics	Technology
Biology		X		X			
Chemistry	X			X		X	X
Computer science		X			X	X	X
Home economics	X	X	X				
Mathematics		X	X	X		X	X
Physics	X	X	X	X	X		X
Technology	X	X	X	X	X	X	

To allow for the variety of combinations, the program possesses a set of basic scientific courses: mathematics, physics and chemistry, the courses specific for the two chosen study fields and the general courses in the theory of education. However, if one of the study fields is mathematics, physics or chemistry, students obtain the required general scientific or mathematical knowledge within the courses specific to the study field in the combination. Due to the rigid requirements of Bologna framework, all students have to collect the same number of credit points (ECTS). For such students one (or two) of the basic scientific courses thus have to be replaced by another course, specifically designed for such “favorable” combinations.

In this contribution we present one of these courses, a course Physics and nature, which is obligatory for combinations of physics with chemistry, computer science, mathematics and technology. The course discusses interdisciplinary problems, contemporary research problems, and other topics, which are motivated by the everyday experiences. Due to the ECTS requirements, the course is placed in the first semester of the study, where practically no verifiable knowledge of physics is present yet. One has to bear in mind that students are coming from various high schools, some of them having no prior physics course at all. Therefore the course and its topics have to be prepared and presented in a way, which does not require the pre-knowledge in physics and the explanations had to be build on experiments, observations and the semi quantitative reasoning only. The type of lecturing should follow the advices for lectures popularizing the natural sciences.

The paper is organized as follows: the course organization and the topics are presented in the next section. The purpose of the descriptive case study of a teaching innovation was to obtain information on two different aspects of the course: the acquired knowledge and how interesting the topics and the course as a whole were for the students. Methods to acquire the information are given in the section Methods which is followed by the section reporting on the Results. In Conclusions we discuss the possibility of introducing such topics into the high school in order to maintain or even stimulate the motivation for physics and natural sciences in general, which is in decline almost everywhere in Europe.

COURSE ORGANIZATION AND TOPICS

As described before, the initial motivation for the course was bizarre. We had to construct a physics course which would not add a serious study load to students but would provide the missing 5 ECTS required by the rigid rules of Bologna in some “favorable” double major combinations of studies. The course had to be placed in the first semester of the study, where the students’ knowledge of physics is unpredictable, as students come from various high schools, some not having physics at all.

The course in duration of one semester (15 weeks) consists of one hour and a half of lectures followed by one hour and a half of laboratory per week. In addition, during the seminar at the end of the course, each student has to present results of a small practical research problem. As our studies notoriously suffer from low enrolment and a number of students with relatively low motivation, the intention was to introduce interdisciplinary and modern topics to increase the motivation for further studies. The topics were chosen such to allow for the laboratory work with motivating and interesting experiments. The choice was the following:

1. *Earthquakes and waves*

The unpredictability of earthquakes and the reasons for their occurrence is discussed during the lecture. Longitudinal and transversal waves are introduced and connected to the real situations during the earthquakes. The secondary effects of earthquakes such as tsunami are presented as well. In the laboratory work students study the stability of model houses of different heights and they make a prototype seismometer.

2. *Dia-, para- and ferromagnetism*

The lecture discusses three different types of magnetism and shows that ferromagnetic materials are not the only materials interacting with magnetic field. It is shown that interactions of paramagnetic materials with the magnetic field are similar to the ferromagnetic ones, only weaker. However diamagnetic materials are repelled by the nonhomogeneous magnetic field. Students study weak magnetic interactions. They observe how the aluminum coin is attracted and how the watery grape is repelled by a strong magnet. They also study the behavior of the superconducting pellet in the vicinity of a strong magnet and the Meissner effect (Čepič, 2007).

3. *Density and buoyancy with respect to the life in water*

The lecture consists of a short résumé of density and the buoyancy; the mechanisms of water animals which provide them stability at a given depth as well as the ability to control and change the depth are discussed. In the laboratory work they construct the Cartesian diver with a special emphasis on keeping the diver at a certain depth in the water.

Students experience personally that pressure affects the average density and the corresponding buoyancy of the diver, however they also experience that the general equilibrium is unstable and has to be controlled constantly. This experiment serves as an illustration that fish have to apply control to remain at a given depth, swimming as a short term control and the constant volume of the fish bladder as a longer term control mechanism.

4. *Temperature control in living species*

The lecture presents the energy balance of the living species with constant temperature. The analysis of the balance with respect to the surface to volume ration was analyzed and illustrated by the experiment where pieces of cheese having different sizes were put in the microwave oven. Students experienced a cognitive conflict as larger pieces melted first and the smallest remain hard. The experiment serves as an illustration that when the heat is released in the whole volume of the body, larger animals have smaller surface to volume ratio which makes it easier to maintain the body temperature higher than the surrounding temperature (Planinšič *et al.*, 2009).

5. *Diffusion and osmosis as transport mechanisms in living species*

The lecture presents the microscopic model of diffusion between regions having different concentrations. For the semi-permeable membranes the phenomenon of osmosis is discussed as well. The importance of these properties in living species is also shown. In the laboratory work students study a toy model of diffusion (Fig.1), where beans of two different colors initially separated in two compartments mix when shaken. Mixing is enabled through an aperture in the fence between the compartments. Students perform the experiment on the small scale individually, with ten beans of each color only. Then they add the results of their simulation together to obtain larger sets of beans showing that the characteristic time for mixing remains the same but the fluctuations are smaller and the possible “demixing” becomes a very unlikely event.

Figure 1: The model for diffusion.

6. *Surface tension and related phenomena*

During the lecture some conceptual problems with respect to the missing interactions at the surface are discussed first. Then the concept of the free energy is introduced in order to bring about better understanding of interactions with various surfaces and the shape of the free surfaces. In the laboratory work students study the dynamics of the flow due to the surface tension pull. They have to make the capillaries by themselves which proves a demanding but a rewarding task (Fig. 2). They also study the shortest street network problem (how to connect four houses with streets having the shortest length altogether) and solve the problem by using a toy model where the streets are soap films.

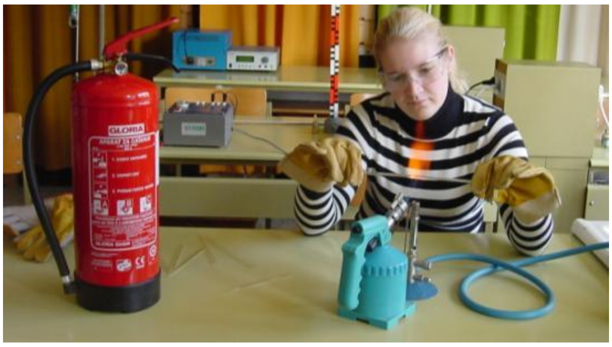

Figure 2 It is difficult to make a capillary.

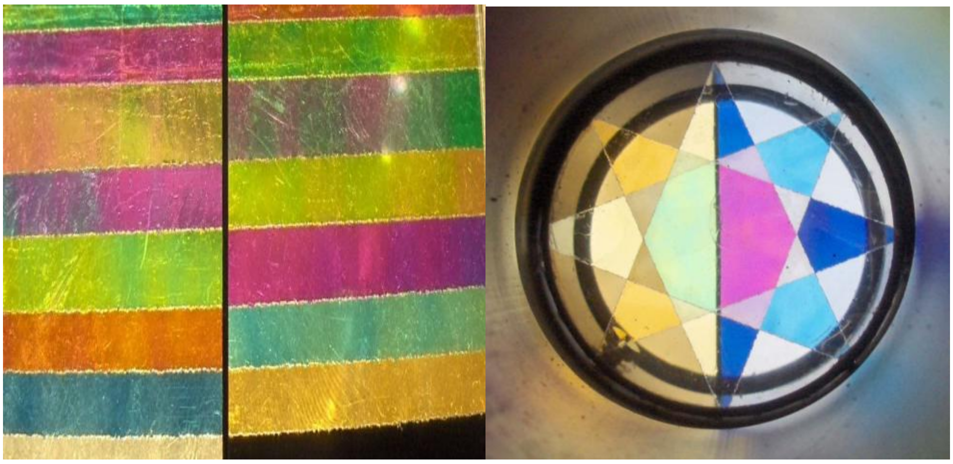
7. *Phase transitions and transport of water in high trees*

The second and the first order transitions, the undercooling and the superheating phenomena are studied. The dependence of the boiling temperature of water on the pressure is also shown. In the laboratory work students prepare the undercooled water and observe its sudden freezing. They play with liquid nitrogen. This is a source of high enthusiasm. They also pull a transparent plastic tube filled with water to high elevations. The tube is sealed at one side and the other open side is submerged into a beaker filled by water. It is shown that water cannot be pulled up higher than a little less than 10 m, where it starts to boil (Susman *et al.,* 2007). So how can the trees pull water up higher than 10 m?

8. *Polarizers, anisotropic materials and the polarization of light*

The lecture starts by introducing the concept of an anisotropic material such as wood. Then the polarized light and how polarizers can polarize light is discussed. In the laboratory work students become familiar with polarizers, they study the effect of the anisotropic material placed between crossed polarizers on the color of the transmitted light (Babič *et al.,* 2009) and they produce a picture which could be observed through the crossed polarizers only (Fig.3).



(a) (b)

Figure 3 (a) Layers of tape seen through the parallel (left) and crossed (right) polarizers. (b) Three tapes glued one on another in three different directions observed through paralel (left) and crossed (right) polarizers.

9. *Liquid crystals*

Liquid crystals are presented as an example of an optically anisotropic material. It is explained how this property is used in displays. Students made a prototype liquid crystalline cell (Pavlin *et al.,* 2009) and a wedge cell which they use to study the splitting of the light beam due to the anisotropic properties of liquid crystalline prism. They verify the mutual perpendicularity of polarizations in the split beams.

10. *Sports and physics*

The energy and its transformations related to the biomechanics, the reaction times of muscles and the important role of the probability in prediction of the football results was discussed during the lecture. In the laboratory work students tested their reaction times, the reasons for tiredness when walking on the horizontal level and the pre-activation of muscles at jumping (Mathelitsch *et al.*, 2008).

METHODS AND RESULTS

Descriptive case study was done. For each topic students answered the pre-test, which questioned the familiarity of the concepts that were studied during the lectures and laboratory work. The pre-test consisted of two or three very short general questions concerning the next topic in the lecturing sequence.

The course was concluded with a written exam. The exam consisted of 13 questions, some of them demanding more elaborate answers. Each topic was questioned at least once. The general structure was:

- 5 questions were asking for facts, which those students, who attended all the lectures and laboratory work, having made notes regularly, could copy from the notes. Of course, the student's understanding of the topic had to be good enough to know, where to search.

- 6 tasks required description of the experiment, recognition of the experiment photo and/or its description, and explanation of the purpose of the experiment. All the tasks were related to the experiments performed by students themselves.

- 4 tasks required application of the concepts learned during the lectures and laboratory work.

Some of the questions in the written exam were the same as the pre-test questions. The results of these questions are analyzed below in more detail.

The points were distributed to the answers unevenly, because some questions were structured having additional sub-questions. The highest number of possible points was 23.

Because the course was implemented for the first time without any previous experiences of the similar type, our aim was to collect from students as much other information as possible. Therefore we constructed another questionnaire, which aimed to assess how interesting or uninteresting the students found the presented topics, their general impression on the course as well as their suggestions for future implementations. In this paper we discuss in more detail the students' responses related to how interesting they found the presented topics.

RESULTS

The group consisted of the first year students of physics education. Majority of students (13) studied the most popular combination of physics and mathematics. The number of students who studied physics and chemistry (7), physics and computer science (3) and physics and technology (3) was much smaller.

The exam is obligatory for students to proceed to the second year of studies, and almost all of the students attended the exam in the first term. The exam lasted for one hour. As mentioned before, the main "mission" of the course was to motivate the students for the beauty of physics. Therefore the exam did not verify the knowledge acquired by heart or the application of the studied concepts to new problems as is typical for exams in the main courses within the physics study program. Students were allowed to consult the lecture and the laboratory notes.

Although we expected that the achieved marks will be almost exclusively the highest ones, this was not the case. Fig. 4 shows the distribution of marks. Only one student failed, which is extremely low in comparison to the basic courses of physics, where the passing rate is usually less than 50%. As they were told in advance they would be allowed to use the notes, many of them had not considered it necessary to prepare for the exam. However, the attendance of lectures and laboratory work has given them enough knowledge to allow for a passing grade.

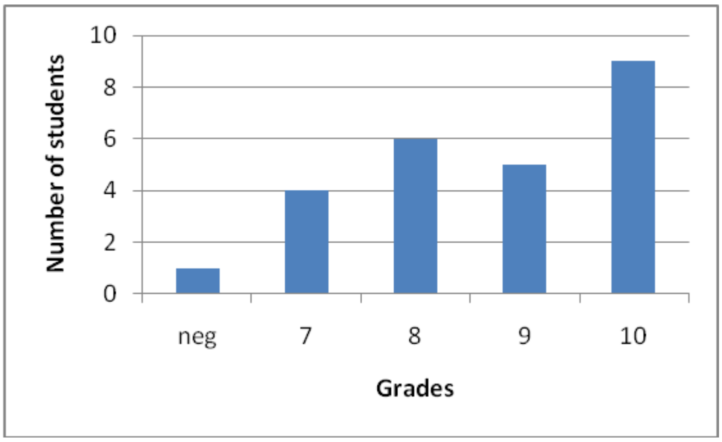


Figure 4 Distribution of the exam grades. Students having 6 or higher passed the exam, 10 is the highest possible grade.

At the beginning of the laboratory work students filled in the pre tests. Each test was composed of three questions related to the theme of the next laboratory work. Some of the questions were designed for checking the level of familiarity with physical concepts and facts. Students were stimulated to write down all the associations or ideas related to the question. From the analysis of the pre tests we were able to detect not only the pre knowledge but we also managed to find out the fields, expressions, terms from physics or from a daily life that were connected to the question. The same questions asked at the post test had, in contrast to the pre tests, the role of appraisement of the terminology and conceptual understanding.

Only the qualitative analysis enabled us to determine the results of the survey. Let us analyze three sample questions with the analysis of students' answers.

Q1: *Compare the terms of magnitude and intensity of the earthquake.*

Q2: How is the kilocalorie (kcal) defined?

Q3: What is osmosis?

24 students took part in the first pre test which included the Q1 on comparison of the magnitude and intensity of the earthquake. Only 5 students gave the correct answer. 4 students did not answer; all the other wrote their ideas of what are the magnitude and/or intensity. The variety of answers is a convincing proof that they have heard about the physical terms such as power, strength, energy, waves, frequency, but they were not able to include them in a logical and conceptually correct statement. At the same time the concepts of magnitude and intensity were sometimes mixed. 23 students who gave an answer used a great number (15) of different terms with ambition to illustrate the magnitude and intensity of the earthquake.

The post test showed a completely different picture. 23 out of 26 students wrote the correct answer using adequate and consistent terminology. Two students had partially correct answers but the way of expressing the idea was correct. There were no incorrect answers and only one student did not answer. One of the possible explanations for the successfulness in answering could be the relevance of the theme with respect to the recent earthquakes. The destructive earthquakes on Haiti close to the time of the exam brought the terminology and terms of the magnitude and intensity to the daily news. Students might become more focused on this topic as they would be if there were no catastrophes at that time. The other possible reason for a large number of correct answers might lie in the fact that students were allowed to consult their notes during the test. Nevertheless this explanation seems less probable since the correctness of other questions was not at the same level.

Tables 2 and 3 show the summary of analysis for Q2 and Q3. The correctness of the answers at the pre and post tests is compared. From the tables one can see the topics that students connected to the question and used to explain the answer.

We also analyzed the responses with respect to the personal opinion of students on different topics, were they interesting for them or not. Although we expected that some of the topics will not be interesting for any of them and some of them would attract most of the students, the results came as a surprise (Figs. 5 and 6). All topics were interesting at least for a few students. Figs. 5 and 6 clearly show the spread of interests and consequently the motivation for students attending the course.

Table 2 The comparison of the pre- and post-test for Q2.

How is the kilocalorie (kcal) defined?							
pre test				post test			
cor.	incorr.	no ans.	explained by/ connected to	corr.	incorr.	no ans.	explained by/ connected to
1	9	14	food (9)	10	15	1	food (7)
			activity, work, burning of material (3)				work, energy, unit of energy (5)
			preserving the personal temperature (2)				other (3)

Table 3 The comparison of the pre- and post-test for Q3.

What is osmosis?							
pre test				post test			
cor.	incorr.	no ans.	explained by/ connected to	cor.	incorr.	no ans.	explained by/ connected to
2	22	3	cells (12)	19	7	0	
			differences in concentrations (10)				

A closer look at Tables 5 and 6 shows that the students interests are different. The same topics which were found the most interesting for many students were found boring for several of them as well. On the other hand, also topics that lecturers considered as more boring cought their attention.

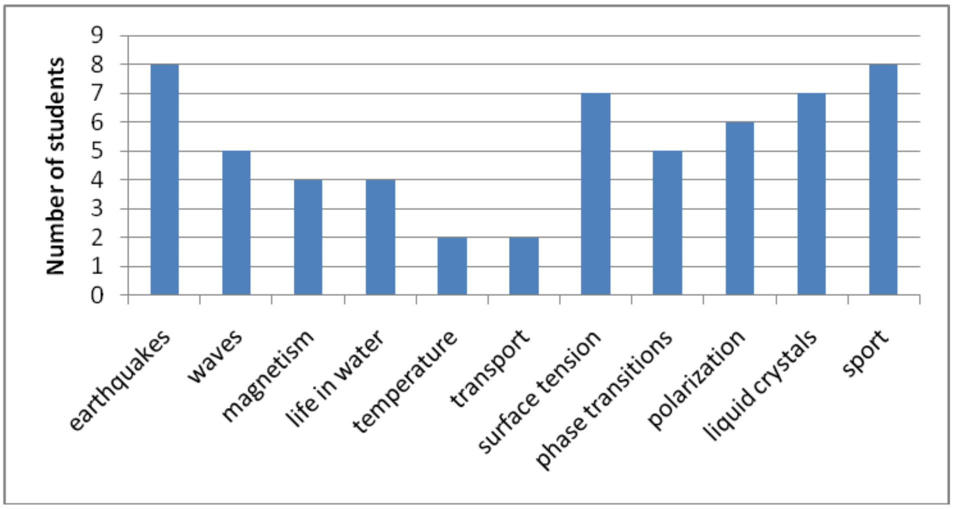

Figure 5 Topics that students found especially interesting. They were allowed to quote multiple topics.

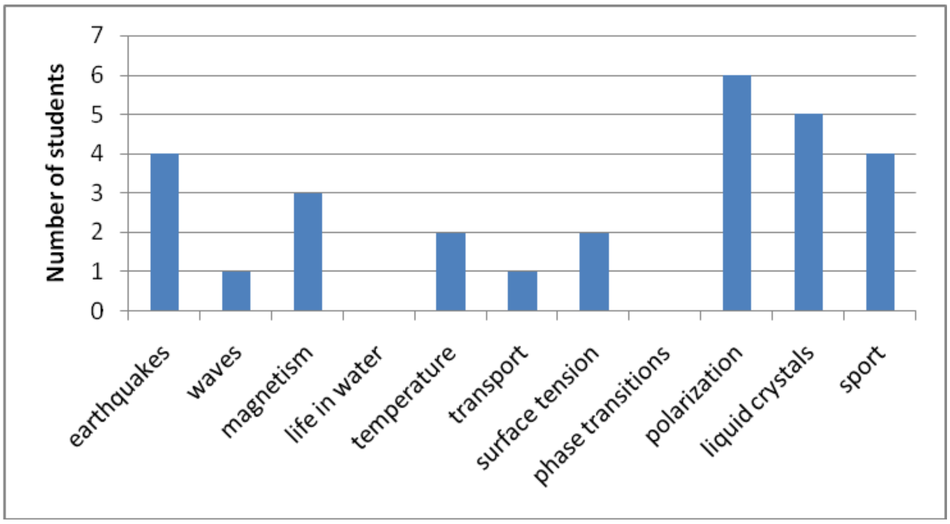

Figure 6 Topics that the students found less interesting. They were allowed to quote multiple topics.

CONCLUSIONS

The new course Physics and nature discusses a variety of different topics. Most of them need a thorough knowledge of physics and math for the correct and detailed comprehension. However, according to our opinion, we managed to present the topics, problems and some contemporary scientific questions at the conceptual level where only very basic pre knowledge in physics was needed. Each topic from the course can also serve as a popular lecture to increase the awareness of public for natural sciences.

The results of the exam have shown that students have acquired many concepts which they will be able to grasp in more depth in the later years of their physics education. They have also reported the subject as interesting and motivating which is seen by their appreciation of different topics.

In addition, as the prerequisite for the subject and its topics was not the in-depth knowledge of physics, the topics prepared and tested may be introduced to the high-school curriculum as well.

ACKNOWLEDGEMENTS

The team would like to acknowledge the interest and the willingness of cooperation of the students in the first year studies of physics education in the academic year 2009/10. The work reported here was partly financed by the Ministry of Higher Education, grant No. J5-0365-0588.

UNDERSTANDING TEACHER PRACTICE USING THEIR OWN NARRATIVES

Peer S. Daugbjerg

The Department of Education, Learning and Philosophy, Aalborg University

pd@viauc.dk

ABSTRACT

This paper discusses ways of understanding teacher practice in educational settings. An educational setting consists of cultural, social and historical elements that all influence the teacher's practice and, how she experiences this practice. It is argued that teaching science and technology is a socially conditioned practice. The teachers' practice are formed by their previous education and experience but also influenced by their private life. This way of looking at teacher knowledge and experience requires attention to teachers' perception of these aspects. Teachers seldom talk about their knowledge of teaching, but they willingly tell their experiences from being a teacher. Therefore it is argued that narratives and life history of teachers can give insight into teachers experience, knowledge and practice. The notion of habitus is used to merge the former experience with the actual practice.

The paper discusses pitfalls and steppingstones in the process of using narratives to understand teachers' experiences and knowledge. Important steppingstones are few questions, teacher written contributions, careful analysis and supplementary collection of observations. Important pitfalls are ideologism, psychologism, exclusion of teachers' perspective and lack of distance to practice. Pitfalls and steppingstones will be illustrated in relation to narratives of Danish science teacher.

Keywords: *Teacher practice, habitus, narrative inquiry, life history, pitfalls, steppingstones.*

WIDENING THE PERSPECTIVE ON TEACHERS' PRACTICE

Teacher practice is composed of many different work functions, where teaching is predominant, others being dialogue with colleagues, principals and parents. Characteristic for all of them is relations to other humans; teachers are therefore constantly engaged in social relations.

The Danish male teacher Knud puts it this way: "*You have to like humans. That is rather important; if don't like humans, if you don't want the contact with other humans, then it probably is a foolish choice, then it is a foolish profession to enter."* I met Knud during a series of life history interviews conducted in the western part of Denmark close to the North Sea. At an age of 40 Knud had been a teacher for 9 years. Knud is a former fisherman, after 10 years of fishing on the North Sea he started taking higher preparatory courses; afterwards he entered the teacher education and became a teacher. Knud was replying to the interviewer's question of whether everybody could be a teacher, this question was posed when they were talking about what it takes to be a teacher. Knud's mildly ironic phrasing of his answer is characteristic for the understated use of speech language is this part of

Denmark. You never exaggerate and you seldom address critique directly. Being aware of this local nuance of spoken language it is easy to see his main point, the deciding factor in the teaching profession is the relations to other humans.

Roth (2002, p. xv) describes how his detailed knowledge on a pupils short-term knowledge didn't help him in understanding the learning difficulties that a particular pupil was facing upon the death of his aunt. His uses this example to illustrate the awareness that he developed when returning to teaching after finishing his doctoral study on pupils' short term memory and learning in science. He realised that theories on the reflective practitioner by Schön (1987) or pedagogical content knowledge by Shulman (1987) didn't describe his teaching practice in its complexity; they all just described parts of it.

These two narratives from actual teaching practice illustrate the social skills teacher have to posses in their relation with other humans in their daily practice. Researcher of all types needs to be sensitive to these and other elements of teachers practice in research in science education. Roth (2002, p. 21) adds a critique of mono-theoretical approaches to education research, which raises questions on how to gain insight in what really matters to teachers in their practice and how to research this. Roth (2002) points to the fact that awareness of details in an educational setting can lead to focus on the significant detail in an actual teaching situation. Roth (2002) was in the actual case acting as a teacher-researcher observing and reflecting on his own practice, but this observation and reflection could also have been done by an academic researcher in dialogue with the teacher. The point is to get the story with the boy in learning difficulties told in its entirety. So by starting with sampling what is present in the classroom we have a better chance for getting back to what is actually the problem.

A Danish female primary school teacher – Helle gives a characterisation of teachers' work, which reflects Roth's (2002) experience of the complexity of the teacher profession.

Helle: "*You must have situational awareness. It's about very fast to pinpoint what is happening here. You should be able to navigate in very many different signals, you must quickly respond to it. Situational awareness is what you have to possess. Then you have to multitask, it's nice seeing that I do not get stressed out by it, damn there may be many things at once. Can't you multitask then ... I have contact to some of my classmates from the teacher education, which some of them have already left the teaching profession because they can't. It is because there is too much going on."* Roth (2002 p. 21) formulates the same experience as follows: *"I noted that in becoming a teacher, there was a development in my capacity to do the right thing at the right moment"*. I met Helle during the formerly mentioned life history interviews. She had only been a teacher for 4 years despite her age of 43 years. She has worked 15 years as an industrial worker. Her last employment was at a male-dominated window assembly plant. She suffered a work injury and had to be rehabilitated. She chose teaching as her new career. The years of working at industrial plants shaped her approach to relations with others: *"I have a sharp tongue and the parents learn that is the way I am."* Helle's former lived experience forms her relation to the parents and her present lived experience of teaching add to these embodied experiences and shape her notion of teacher practice. I shall return to such embodied experiences later.

Jacobsen (2004 p.15) discusses ambiguity using Ziehe's writings on youth culture. Ambiguity is increased in the contemporary society, but it also gives great satisfaction being able to cope with it. Helle's narrative above illustrates this point by giving a picture of the awareness on details and ambiguities in the teaching situation among the teachers' we met. Such an awareness we academic researcher also have to develop in order to provide recognisable pictures of science teaching back to the science teachers. Carr (2006) discusses educational theory and its relation with practice, he emphasises in his conclusion the need for practical justification of educational theory (ibid. p. 155). Roth (2002. p.21) joins this view as he says "*I believe that the ultimate test of theories is the capacity to explain subjective human experience"*.

UNDERSTANDING TEACHER PRACTICE USING KNOWLEDGE AND EXPERIENCE

Research on science teacher practice is conducted by both academic researcher and by science teachers. Science teachers own research provide an inside perspective on science teaching practice, whereas academic researcher provide an outside perspective. Both approaches have benefits and pitfalls. Inside perspectives are often very true to the context with the advantage of providing direct improvement to the actual practice, but being without value in other contexts. Outside perspectives tries to decontextualise the developed knowledge in order to make it valuable in shifting context, a process that renders it of less value in the context where it is developed (Roth 2007, Jenkins 2000).

Many investigations focus on development, change and intervention, very few deals with analysis or description of the actual status. This renders the departure point for development and intervention uncertain. Therefore the following improvement and its direction is sometimes blurred (Hewson 2007).

Roth (2007) reviews the approach of science teachers as researchers. The majority of these studies are conducted during part of pre-service and in-service teacher education or professional development. The research is often part of the assessment of changes in practice generated by these interventions. Roth (2007) states that high-quality inquiries and analyses should prompt teacher researchers to develop new understandings that have implications for his or her teaching and improve students learning (ibid. p. 1241-1242). She recognizes that it is a high bar to hold up. She presents no reflections on where in their teaching career the involved teacher researchers might be in relation to their capacity or motivation to make such improvements. Hewson (2007, p.1200-1202) notes in his review of science teacher development, that it is not possible to paint a coherent picture of the best way to perform science teacher development. He summarizes his findings in a 3 step model 1) define starting point, 2) define end point and 3) the ways they might be connected. Combining these two notions of development it would seem fair to include attention to teacher experience and work conditions in the 3 phases suggested by Hewson in order to increase the ownership of the developmental process.

Tsai and Wen (2005) gives a quantitative review of the content of research presented in three leading journals, they analyse 802 papers. They find that 7% deals with Teaching, which is the category that includes teacher thinking, behaviour and strategies along with teacher knowledge. This indicates that teacher knowledge and teacher experience is not a dominant research field in science education at the moment. Contemporary international research in science teachers' professional development is reviewed in the Handbook of Research on Science Education edited by Abell and Ledermann (2007). These reviews show that the research has its primarily focuses on individual teachers' knowledge, attitudes and beliefs. The notion of teacher knowledge has several prominent theories such as Pedagogical Content Knowledge (PCK) and Subject Matter Knowledge (SMK).

PCK is often presented as an integrative approach to the science teacher profession (e.g. Gess-Newsome and Lederman 1999, van Driel et al 1998), that weaves together different representations of experience. The PCK tradition prescribes experience and narrative accounts to be processed in order to serve as basis for learning or development. The intention of collecting narratives in this tradition serves a larger purpose namely the description of the PCK of the individual teacher. This individual focus might lead to superficial analysis of the narratives. Teachers' knowledge on science and technology or on science and technology education does not provide the full picture of how they perform their work as teachers and how they understand this work.

Teachers in the school are not isolated islands; their professional knowledge is socially conditioned. Kosonen and Houtsonen (2007) explore this point by using the Bourdieu notion of habitus. The interaction with the pupils is influenced by a lot of other factors, that Kosonen and Houtsonen summarizes in the habitus of the teacher. They state:

"Their [the teachers] habitus are formed by past practices in different settings, especially, in their professional education and training, in their work and career, and also in their personal lives" (Kosonen and Houtsonen 2007, p.172). Roth (2002, p. 45) describes habitus in an educational setting as "*the patterned ways in which we interact with the world, including those practices that embody actions, perceptions and expectations."*

This way of looking at teachers' knowledge requires attention to their perception and appreciation of their own experience and knowledge and how they see this in relation to colleagues and pupils. Helle and her sharp tongue is an example of how past and present experiences merges to form a coherent notion of a practice. I will use this notion of the habitus as embodied experiences to summarize my main points in the conclusion.

This insight in teacher understanding of their practice is brought forward by the use of a teacher's own language about her own practice. Jenkins (2000, p. 21) summarizes his health check on research in science education by stating: *"Is it perhaps because the research community fails to grasp the complexity of teaching science or lacks an adequate indigenous pedagogical language and conceptual structure with which to capture what really matters about teachers' work? … It isn't simply that the existing language fails to capture the essence of what teachers do when they teach science. It can also present a seriously mis-leading picture of what is involved in teaching."*

Roth (2007) quotes a few studies that argue for rising the teachers own voice in science education research (ibid. p. 1236). This indicates that it is not a very strong tradition in science education research. Furthermore teachers seldom talk about their knowledge of teaching, but they willingly tell their experiences from being a teacher. Lortie (1975 p. 77 ff) and Müller et al (2007 p. 4) has interviewed teachers. Their findings furthermore point at experience as being the significant mode teachers learn teacher practice. Perhaps we as academic researcher should lend more ears to the narrations of the teachers when they are talking about science education in order to understand the experience and knowledge at play in science teaching.

NARRATIVE RESEARCH STARTS FROM THE TEACHERS OWN LANGUAGE

The use of narrative inquiry in creating an understanding of the work conditions of science and technology teachers is an inclusive approach that unveils details and ambiguities. As discussed earlier details are important in order to understand the complexity of teaching in its entirety. The narratives about the context of teaching from Roth (2002) and the informant

Helle presented earlier illustrates the contribution narratives give to understanding which detail to focus on in the actual situation. A given narrative contains many opportunities for interpretation but the relevant one can only be chosen through simultaneous understanding of the context of the school, including pedagogical trends, colleagues, curricula and ongoing reform processes (Elbaz-Luwisch 2007). In this process of understanding the context of the teacher's work it can be beneficial to include some aspects of the life history of the teacher (Goodson 2008, Clandinin and Connelly 2000) as illustrated by the way the informant Knud talks about being a teacher.

An example of presenting interesting stories of teachers is the cohort study by Goodson and Numan (2003) on a class of Swedish teachers who graduated in 1960. These stories tell about the changes in the Swedish primary school over a period of 40 years. Many interesting aspects are raised by the teachers, but the presentation given by the authors lack exhaustive analysis of the circumstances and contexts that might have extracted knowledge of more general interest from this impressive material. A want the authors themselves are aware of as they promise to provide (ibid. p. 228) this analysis in a later publication, unfortunately this publication is still lacking. The details and ambiguities is overwhelming in such a large set of data, therefore you need to choose a theme that you want to focus on – it can be how former life experiences can form the teacher in their relation to pupils and parents as given by the examples presented from my own life history interviews, or it can be becoming a science teacher (Roth 2002).

Clandinin and Connelly (2000) stress that narratives are the best way to get teachers experiences verbalized. A narrative includes interpretation, reflection, history, environment, relations, ontogenesis and exclusion of experiences. It is not an accurate and true version of the teachers' past but a recollection of past experiences recreated in the dialogue with the researcher.

Narrative interviews

Kvale and Brinkmann (2009) give detailed guidelines on how to perform different types of interviews. They stress that the narrative interview focuses on the stories the informants tell as well as how they tell them. The narratives are the fundamental given data in this type of research. The narratives are either told freely or the interviewer helps constructing them through questioning the informant. It is important that the interviewer clarifies details in the storyline, so that conflicts, solutions and tensions are formulated by the informant. Researchers affect the participants. Their questions start reflection and development among the participants. The narrative emerges in the dialogue between participant and researcher; it does not exist prior to this dialogue.

Herman and Vervaeck (2005) present the main characteristics of structuralism in their *Handbook of Narrative Analysis*; they distinguish between the Narration, the Narrative and the Story. The Story includes events and presents the characters involved, the Narrative gives the timeline, details about the characters and the focus of the story finally the Narration is the actual dialogue – the spoken words – and actions between the characters. This distinction between the elements in a story is good structuring tools in the process of selecting relevant details for further analysis.

Life history

Bruner (1984) defines a life history as: *"A life as told, a life history, is a narrative, influenced by the cultural conventions of telling, by the audience, and by the social context".* Goodson

(1992) distinct between life story and life history, his notion of life history is in accordance with Bruner including contextualisation; but he introduces life story to describe life as told as merely the story without elaborate inter-contextual elements developed by the researcher.

The researcher arranges the narratives in chronological and contextual order to create a coherent life story. This life story is related to essential historical events regarding society, school, science and science education creating a life history of the science teacher. This work involves an analytic and interpretive process where the researcher is looking for harmony and interaction between teachers narratives and experiences on the one hand and on the other hand the historical context. In this process the researcher sensitivity towards the teacher's life and the evolution of the society is essential to avoid intimidation of the teacher.

Clandinin and Connelly (2000) stresses the importance of this part of narrative research, they describe it as composing a research text based on the interviews. A research text includes the story of the researcher in the inquiry, the story of the participant and the larger landscape on which they all live. Clandinin and Murphy (2009) further elaborate this point of view as they state that the research text speaks to 3 audiences: the participants, the researcher and a larger scholarly and public audience.

The relation with the participants is of great importance, so that they remain ownership to their statements (Roth 2002). It is important to maintain the original coherence between conscience and the historically lived life of the participants in order to fulfil the relational responsibilities of representing the experiences we co-construct with the participants (Clandinin and Murphy 2009).

Lortie (1975 p. 79) raises an interesting methodological problem as he writes: "*... socialization into teaching is largely self-socialization; one's personal predispositions are not only relevant but, in fact, stand at the core of becoming a teacher."* This could indicate that psychological interviews would be the best way to understand teachers' notions of teaching. Leontjev (1981, 267-271) points to the difficulties in trying to understand human activity as psychological processes. We have primarily access to the external notions of the teachers' experiences through the physical statements and utterances they produce. We do not have insight in their inner reflections unless they provide us this insight through their utterances. Narrative research is not providing psychological insight or evidence it provides narratives that can be interpreted in relation to relevant historical, cultural and social conditions. Clandinin and Connelly (2000 p.50) describe dimensions for analytical handling of these conditions. They first describe inward, outward, backward and forward directions of experience. The inward direction relates to feelings and moral dispositions. The outward direction relates to the environment. The backward and forward directions relates to time. They condense these 4 directions to 2 dimensions one dealing with inward-outward and one dealing with backward-forward, then they add a third dimension space, that deals with the landscape of inquiry. I would like to sharpen their definition of these dimensions. I see one dimension dealing with the time line of events and experiences, another one dealing with the educational settings of the events and experiences and a third dealing with social and personal relations of the events and experiences. This is in agreement with Goodson (2008) who emphasizes the importance of relating the personal teacher story to the more general history of changes in the school. Furthermore the coherence between the time and the settings dimensions can be analysed using Bakhtin's notion of chronotope (1981, p. 84), this notion grasp the interplay between time and space in narrative analysis and inquiry.

HOW CAN NARRATIVES CONTRIBUTE TO OUR UNDERSTANDING OF TEACHER PRACTICE?

In following I will present yet another teacher from the life history interviews conducted from January to March 2009. I will give a more extensive introduction to him in order to shed light on his handling of a difficult teaching situation.

Jesper (male 53 years, 24 years as teacher) grew up in a village in the western part of Denmark near the North Sea, this part of Denmark is called West Jutland. He was originally trained in trade and office in a larger town 15 km from his birth place, after finishing this training he worked in an engineering company in a larger town on the east coast of Danish peninsula Jutland for 2 years. He finds the work boring, so he moves back to his birthplace in West Jutland. The story of Jesper entering the teacher profession is interesting as he moves back from the more densely populated east coast of Jutland to take a teacher education and work locally as a teacher subsequently. This move back west is unique; very few people who have left the western coastal region moves back again. His upbringing in West Jutland retracts him to this part of the country. The teacher education is one of the few available higher educations in the local area. Jesper had already after finishing high school considered becoming a teacher, but due to family tradition he chose otherwise in the first place. A choice he later regretted and returned to become a teacher "back home".

Jesper teaches primary science and mathematics. Jesper describes the problem with large class and the need for differentiated teaching.

"Now we have classes that are huge, so it was no way the way I thought it would be. We did not know initially that they would be so big. In mathematics, it is not possible to do practical work. I've tried dividing the class, and then take care of one half and then have the other half do something themselves. It's not a solution, I tried it 3 times and then I went back to having the entire class together. Of course you have a lot of different activities and they work in groups. Many changes to give variation to the lessons, but they are always under control, because those who do not want to do something. You always have to keep an eye on them. It is rather difficult, but goes fairly well."

"There is a teacher's aid here, she should be in every Friday in the 2nd module, but she has not been there yet because either she has been sick or she has been set to do other practical chores here at school. Today I came and had again planned and duplicated ten sheets she had to work with 10 vulnerable pupils who actually just is being fobbed off, as we can not get at them because there are too many, then I will teach the 20 who can and will on their own. You know it's not something we hide. It is somewhat sad to see a group that is falling through. It has been reported to the office many times. I've had the headmaster down a few times because she has to see it. She says it is such an ordinary working situation. I can not expect to get them all to work, but it is a big group that never has any benefit of the teaching"

"On the other hand, when they are divided in small teams in primary science it works well, and you will learn to know the pupils much better."

This report describes a teacher with a professional dilemma of wanting to do more than he can overcome on his given conditions. Jesper know he can make a difference to more pupils if he had other conditions for his work. The context is a small rural school with only 30 pupils at this year level. A division into two classes will cost the school more hours to be paid to the teacher, which then will reduce the economy for the entire school as it is paid per pupil not per teacher work-hour. In order for all pupils to achieve well in mathematics the right thing to do professionally would be two minor classes, but this collides with the economic conditions given this school in a rural area of Denmark. In an international perspective class with 30 pupils are not rare, but this is not relevant in the actual case where the teacher experiences that he is not able to differentiate detailed enough to reach all his pupils. His frustration on the situation in the mathematics class is also affected by the fact that in the integrated primary science class he has the class divided into 2 teams of 15, and here he experiences, that all the pupils participate and contribute to the learning in the classroom. So he knows that all the pupils can be reached but his conditions for doing this are different when he teaches the two subjects. The story illustrates the cultural and social conditions that govern his possibilities for teaching according to his personal and professional optimum.

Jesper has deliberately chosen the teacher profession in this part of the country after trying something else. His devotion to the teaching profession and the well-being of his pupils is uttered in a low voice, because he also realises that the economic constraints put on the school can't easily be changed. Despite his frustration there seems to be established a harmony between the teaching profession and the attachment Jesper has to the local area. Muel-Dreyfus (1983) talks about this harmony between humans and professions, she states that*: "People choose a profession and the profession makes them it's chosen ones."* Roth (2002) would with Bourdieu say that Jesper's habitus is to deal with these conditions without making a big fuss of it.

In this example of interpretation of a teacher narrative I have included my general knowledge of the local area. I have managed to get Jesper to tell a coherent story about a part of teacher work that worries him. I lack making observations of his teaching in order to get a more detailed understanding of the problems he is telling about.

These things would improve my foothold in walking in the landscape of teaching science and mathematics in a rural part of Denmark

My intention has been not to prescribe either psychological or theoretical explanations on Jesper's story and I have tried to stay close to the perspective Jesper present. My intention has though been to avoid ending in a pitfall of practice from where the applied reflections would lack a general overview of teacher practice. I have aimed at giving primarily sociological explanations of the narrative.

Not every aspect of narrative research can be illustrated from a single example, but some of the qualitative benefits and points of caution can be presented.

Steppingstones working with narratives

Combining my own experience with recommendations from Ivor Goodson (see e.g. Goodson 2008) some steppingstones can be formulated for the work with narrative research:

Ask few open questions – like these*:*

- Tell about your childhood and home?
- Tell about your teenage years and schooling?
- Tell why you chose teacher education?
- Tell about how you plan and perform your teaching?
- Tell about what the next development move is going to be?

Make the teacher write: About a limited number of significant episodes, in their teacher career.

Make supplementary interviews and observations: After analysing the collected material it can be necessary to collect further narratives, information's or observations in order to have a rich understanding of the life history.

Keep open for the personal voice of the teacher: Teachers can be exaggerating in order to promote themselves, they can be understating as an ironic distance or in order to appear as victims, they can be objective leaving little space for their personality to show or they can be empathic focusing primarily on the relations to the students and colleagues.

Make detailed analysis of the utterances: This extracts more knowledge from the narratives by 1) analysing for intonations and pauses (see Roth and Thom 2009) or 2) linguistic analysis see Herman and Vervaeck (2005).

Analyse for what matters in teacher practice: The analysis can proliferate from looking for the 3 significant teacher competences identified by Nordenbo et al (2008):

1) Teacher relation to the individual pupil – social relation competence;

2) Teacher relation to entire class - competence to make class rules and support pupil autonomy;

3) Didactics and subject matter competence.

Pitfalls working with narratives

The process of interpretation and contextualisation contains several chances to trip over blind spots and dwell comfort zones. It is important to be aware of these in the process of creating a true and valid life history. The following list is inspired by Elbaz-Luwisch (2007) and my own experience:

Beware of ideologism: The teacher's life history is unique, it is not the entire truth about science teaching, and it does not serve a politically correct agenda within education or research. Bourdieu (1999) provides reflections on how to grasp the social conditions of which informants are the product.

Beware of psychologism: Narrative research is not therapy; it tries to understand not to cure. Leontjev (1981) gives guidelines for a dialectic approach to reflection and activity. Husserl (1999) advocates for a phenomenological reduction in order to start with the immanent and observable given facts.

Beware of causalities: The interpretations shall qualify relations, causes and actions with care and empathy for the teachers work conditions and private life.

Beware of excluding the teachers' perspectives: The teacher can have mixed motives for their choice of career and their mode of teaching.

Remain critical towards practice: Narratives interviews are collected in an atmosphere of confidence, this confidence can become a blind spot in the interpretation process.

CONCLUSION

The 3 teachers you have met in this paper all have changed to the teacher profession after years of other work. They all have a sharp focus on the main work function in the teacher practice – teaching. They clearly have become teacher. Their habitus has changed from their former careers to the teaching profession, in this change their former experiences have been supplemented with new experiences. They consolidate their present habitus by giving clear statements on central aspects of the teaching practice. Given the opportunity to tell about their experiences with the teaching profession they all do this in a committed manner.

In the article I have been trying to illustrate the qualities of narratives in providing insight in teacher practice. I have theoretically positioned narratives as a significant element in teacher practice research because it contributes with the teachers' perceptions and experiences of their own practice. Narratives construct the past in the present. Narratives give a language to teachers' disposition for doing their job. The teachers' dispositions are structured by their past and are structuring their presence and future.

To understand teachers we need to know their history and how they have experienced it. This is the basis for their present teaching and for their potential to develop their teaching. The history of teachers is more, than is normally assessed by looking at their knowledge on pedagogue and subject matter. I do not reject that assessing teacher knowledge can contribute to understanding their practice. I only say that using narratives unveils subjective understandings that are close to everyday teacher practice.

ACKNOWLEDGEMENTS

I would like to thank VIA University College for funding the work with collecting the life history interviews. I would like to thank Lecturer Kurt Lyhne, VIA University College for the cooperation in collecting the life history interviews used in this paper. I would like thank Head of development Søren Gytz-Olesen, VIA University College; Professor of Sociology Annick Prieur, Aalborg University and Professor of Education Paola Valero, Aalborg University for fruitful dialogue in the process of analysing the life histories of the teachers.

TESTING THE TEST: WHAT CONSTITUTES SCIENCE IN THE BRAZILIAN HIGH SCHOOL (ENEM) NATIONAL TEST

Everaldo dos Santos

Paraná State Educational Board, Brazil

cgioppo@yahoo.com

ABSTRACT

This study analyzed a Brazilian High School Test called ENEM. The test was first used in 1998 and assesses High School students' knowledge according to the Brazilian National Guidelines (PNLD). Our goal was to compare the reference test matrix and the proposed questions of 2007 and 2008 with the four Science Education strands delineated at NRC report (2007). We also compared matrix and questions with Anderson and Krathwohl (2001) Taxonomy for Cognitive Domain. Results of NRC/ questions comparisons show that most questions followed only one strand that focused on the content - not on the processes of science, its history, or inquiry. Results for Taxonomy/ questions comparisons revealed the test is prepared primarily with low level reasoning questions. Conclusions indicated the test does not evaluate whether students gained a broader perspective of science, and how science works. Thus, even if the test does not focus only on memorization of information, it is very difficult to discuss what science really is, and how explanations and models are built. There is a lack of questions on the processes of science, on the history of science and on inquiry that could generate an interpretation of the nature of science among pupils. Additionally, if we understand that the test is used nationwide and is able to change policies in Education, policymakers should look carefully to what strands are missing and how the test can effectively evaluate science understandings.

Keywords: *Assessment, Science Education, High School.*

INTRODUCTION

In Brazil there is a high school National Test called ENEM. This test is used nationally and has grown increasingly significant among students, high school teachers, and the college policymakers who decide university entrance policies. It evaluates not only students Knowledge from different High School subject areas but also indirectly the Brazilian Educational Systems. In 2009, the Brazilian Ministry of Education proposed to university policymakers that they adopt the Test as a component of the students' entry into College. There was much criticism particularly regarding the interference of the National minister in the issue of university autonomy. Despite the criticism, many public universities decided to adopt the test as one part of the grade. Faculty members checked the test and complained about it. The main argument used against ENEM is the test is too broad and shallow to evaluate students' knowledge and should not be used as a university entrance tool. This paper will discuss this dispute.

The questions are prepared based on a reference matrix which structures the test. The matrix includes five competencies and 21 abilities considered essential to the students on this level. The test has 63 questions (3 for each ability) and there is no distinction among courses or disciplines, thus questions may present concepts related to more than one subject area of school knowledge or presented in any high school course. Knowledge about Natural Sciences is presented in questions that sometimes are not evident to evaluate scientific knowledge. Only after a careful reading is it possible identify the scientific knowledge being tested. The intention to ignore or to clearly evaluate scientific knowledge is presented only in competencies One and Two. Competency One suggests that the student should have "Comprehension of the Portuguese language norms to use math, artistic and scientific languages" (MEC, 2008). Competency Two indicates the need to "construct and use concepts of many subject areas to comprehend natural phenomena, historic-geographic processes, the technological production and the artistic displays (MEC, 2008).

Considering the reference matrix is based on competencies and abilities that all students should have, we understand that ENEM test is not only a high school exam but also a policymaker on the public and private sectors of education. We will also address in this paper, an analysis of questions presented using Anderson and Krathwohl, (2001) revised taxonomy for cognitive domain.

In Brazil, until the 1990s, most of the National and State tests of different grade levels were based on Bloom's taxonomy (1956). Typically, only three basic levels of the Taxonomy (knowledge, comprehension and application) were used on the reference matrix. After that, The Paraná State Board of Education suggested that a matrix based on Bloom's taxonomy should be replaced by another one using attitudes, process skills and conceptual approach (Coll, Pozo, Sarabia and Valls, 1998) to assess students However these names were not used, instead the matrix used Basic, Operational and Global levels of questions.

When the ENEM test was created its designers preferred using the idea of competencies and abilities to outline the new matrix. ENEM test reports and documents stated clearly the intention of matching with the National Guidelines, also based on Competencies and Abilities. Designers argued that students should be able to analyze real situations and be able to react to that. Macedo and Lopes (2002) criticized the national Guidelines and the very idea of competencies and abilities. They pointed out the differences between scientific and school knowledge, showing that school knowledge is organized to be taught. This organization is a sort of pedagogical filter that has a cultural framework and guides the content selection beyond the epistemological criteria.

Krasilchik (2000) studied the history of Science Education in Brazil and emphasized that, educational policies such as the Brazilian Guidelines for Education (and ENEM test) have intentions related to the social, historical, political, economical, and cultural moments. She argues that all these issues influenced more the design of Brazilian Guidelines (and nationwide tests) than the scientific production itself.

Thus we identified at least two tensions. The first is related to the scientific knowledge versus school science knowledge selection. What should be taught and then assessed in a high school nationwide test? The second tension is related to the idea of competencies and abilities as a guideline for Science teaching and learning. Are the tests addressing the major issues of the Natural Sciences?

To address these tensions we looked for studies that tried to see the big picture and give some orientation for Natural Sciences textbooks, curriculum or guidelines.

The US National Science Education Standards – NSES (NRC, 1996) framed eight categories for content standards: unifying concepts and processes in science; science as inquiry; physical science; life science; earth and space science; science and technology; science in personal and social perspectives; and the history and nature of science.

Years before, Yager and McCormack (1989) proposed six domains for School Science Programs: concept; process; creativity; attitude; application; worldview. Yager also actively participated on the preparation of NSES standards. Recently he proposed an interaction of the six domains with the Assessing Science Learning (Yager, 2010). His proposal is summarized on Figure 1:

Figure 1: Interaction of the six domains for teaching and assessing Science Learning.

Concept Domain Process Domain	The typical focus for traditional teaching (i.e. basic science concepts and skills)
Creativity Domain Attitude Domain	The two enabling domains (i.e. questioning & personal/ social engagement).
Application Domain	Using concepts and processes in new contexts (i.e. living in the whole world with use of science as defined by NSES)
Worldview Domain	Examining the philosophy, history, and sociology of the whole science enterprise (i.e. where most people live and operate when not engaged with science directly)

(Note: framework designed by Yager, 2010, p.11)

Chiapetta et al (1993) focused on science textbook evaluation and proposed four aspects of scientific literacy: a) Knowledge of Science; b) the investigative Nature of Science; c) Science as a Way of Thinking; d) Interaction of Science, Technology and Society (STS).

More recently the US National Research Council (NRC, 2007) prepared a report for Science Education that point out four strands to be proficient in Science.

> Students who are proficient in science:
>
> 1. know, use, and interpret scientific explanations of the natural world;
>
> 2. generate and evaluate scientific evidence and explanations;
>
> 3. understand the nature and development of scientific knowledge; and
>
> 4. participate productively in scientific practices and discourse. (p.36)

These strands were used in this study to evaluate the tests and its matrix. Our main goal was to compare the reference test matrix and the proposed questions of 2007 and 2008 with the four Science Education strands delineated at NRC report (2007).

METHODS

This study was a document analysis of the Brazilian National high school Test (ENEM). Initially we analyzed 2007 and 2008 tests comparing them with their own matrix. After that we compared the test and its matrix with the four strands presented at the US NRC report (NRC, 2007)

We decided to use the NRC (2007) as a basis for this analysis because we understand that this report compiles many studies on the area and identify issues that are also important for Brazilian students.

As for the tests and matrix chosen, we used 2007 and 2008 because the matrix and test for 2009 changed and part of the test is now more related to subject areas, thus in order to compare tests and matrix to the strands, we preferred using previous years.

After using NRC (2007) report to categorize test matrix and questions, we also used Anderson and Krathwohl (2001) Taxonomy for cognitive Domain. These authors reviewed Bloom's taxonomy (1956). Even considering Bloom's taxonomy dated for Science Education, we have to agree that most tests all over the world are still based on it, especially the ones related to the cognitive domain. In this study we wanted to check if ENEM test was, in fact, based on competencies and abilities as it is supposed to be or if competencies and abilities would be in fact only a make-up for Bloom's taxonomy.

RESULTS AND DISCUSSION

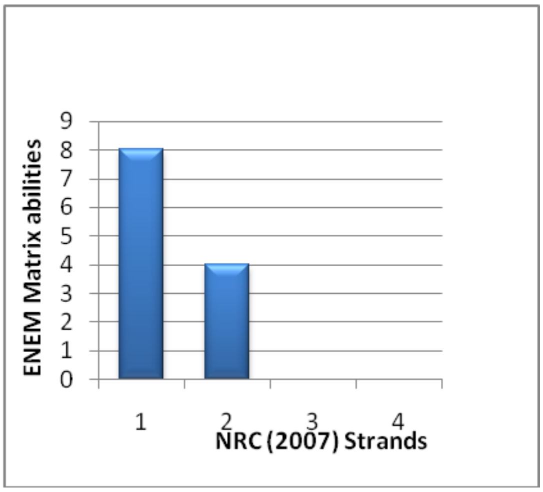
Matrix Analysis:

The intention to evaluate scientific knowledge is formalized on competencies I and II. Competency I suggested that students should have "dominium of Portuguese Language norms and the correct use of other "languages" such as mathematical, artistic and scientific (MEC, 2008). Competency II indicates the need to "construct and apply concepts in many different subject areas to understand Natural phenomena, historic and geographical processes, technological production, and artistic issues" (MEC, 2008).

Looking at the test matrix and its competencies it is possible to infer that ENEM is being used not only as a regular test but it also intends to be a guiding principle that affects policies and policy makers in a public and private sectors of Brazilian education. Furthermore its influence is growing since its results are now being used as a method for entering the university. Test questions present different ways to assess students' cognitive domain (Anderson and Krathwohl, 2001) and guide a conception of Science Education.

On the other hand, the division in competencies and abilities of the ENEM test matrix is one dissonant point with the actual Paraná State Standards (and also many other state standards) because the State Standards were created based on disciplines and ENEM matrix and test is not. Paraná state Educational Board is reluctant to accept the idea of competencies and abilities and formally mentioned that teachers should not base their class plans on that. Figure 2 shows the relation of the matrix abilities with the NRC (2007) four strands.

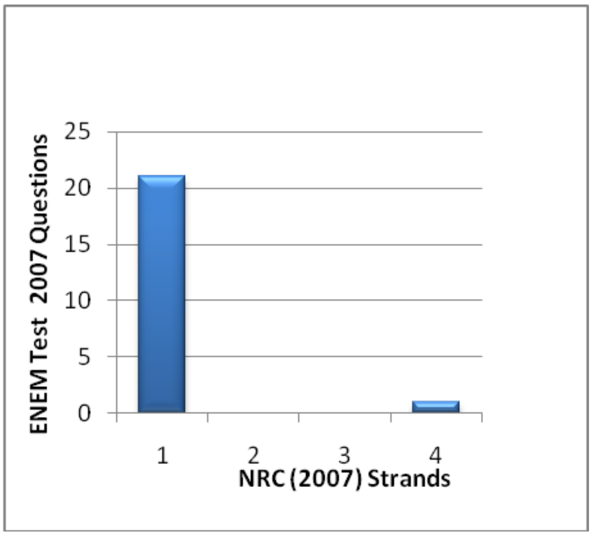
Figure 2: Relation between matrix abilities with NRC (2007) four strands.



Tests Analyses:

Considering that the abilities are not subdivided in disciplines we had to select the ones that referred to the Natural Sciences. In order to select and categorize abilities we looked at them and then checked the tests and test reports. We also checked levels of reasoning following Anderson and Krathwohl (2001). The chosen ones can be categorized into two NRC Strands: 1. know, use, and interpret scientific explanations of the natural world; and 2. generate and evaluate scientific evidence and explanations. On the first strand are abilities that needed the comprehension of scientific concepts, principles, theories, and to understand natural phenomena. On the second strand are abilities that can somehow be related to data analysis and inquiry, even if the inquiry is limited to data analysis on the questions. No abilities were included on the categories 3 and 4. It means that there were no relation to the History and philosophy of Science and also no relation to the social use of scientific knowledge. Figure 3 presents number of 2007 ENEM test questions related to NRC (2007) four Strands.

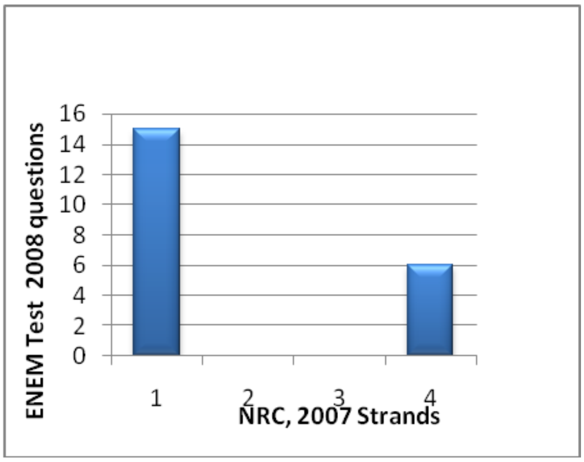
Figure 3: Questions of ENEM test 2007 test related to NRC (2007) four Strands.



Most questions somehow related to scientific knowledge on 2007 ENEM test are on Strand 1. These questions mention scientific laws, theories and concept knowledge to understand a phenomenon. There was only one question on Strand 4, related to discourse practices and the social use of scientific knowledge. It is interesting to note that there was no ability directly related to this strand but it did appear in one question.

As for 2008 questions results showed that two thirds were also categorized as Strand 1 but we could see that there are more questions related to discourse practices and the social use of scientific knowledge. In this case the questions of strand four were related to environmental issues. Figure 4 shows the number of questions on ENEM test 2008 related to NRC (2007) four Strands.

Figure 4: Questions of ENEM test 2008 related to NRC (2007) four Strands.



According to the National Research Council (NRC, 2007) it is important to teach Science because

1. Science is a significant part of human culture and represents one of the pinnacles of human thinking capacity.

2. It provides a laboratory of common experience for development of language, logic, and problem-solving skills in the classroom.

3. A democracy demands that its citizens make personal and community decisions about issues in which scientific information plays a fundamental role, and they hence need knowledge of science as well as an understanding of scientific methodology.

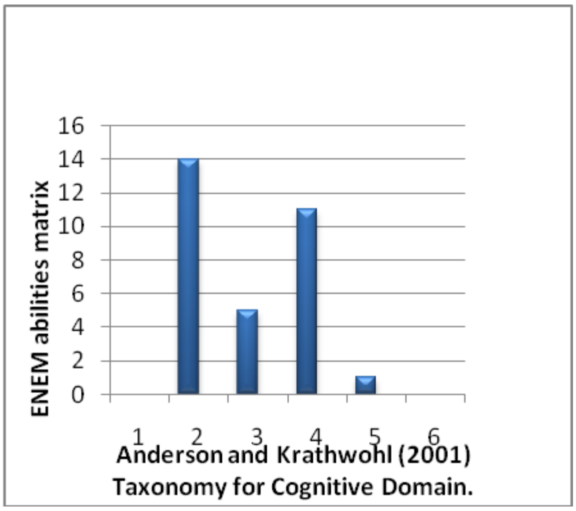
4. For some students, it will become a lifelong vocation or avocation.

5. The nation is dependent on the technical and scientific abilities of its citizens for its economic competitiveness and national needs. (p.34)

If we consider that most of the questions are related to only one strand we can infer that the test is not able to address all the needs for Science Education and citizenship and this is the most important issue of this analysis.

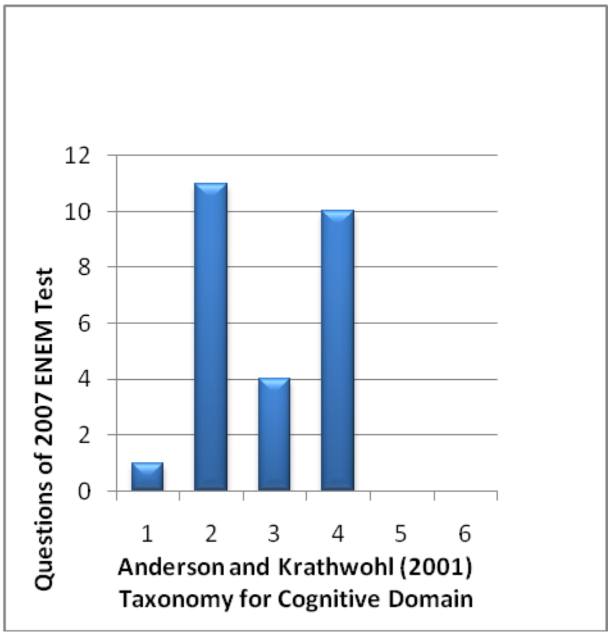
As we mentioned before, besides the NRC report (2007) we also used Anderson and Krathwohl (2001) revised taxonomy for cognitive domain to categorize the test questions and the abilities listed on the test matrix. Their taxonomy considered six levels of cognition, from the less complex to the more complex: 1) remembering; 2) understanding; 3) applying; 4) analyzing; 5) evaluating; 6) creating. Figure 5 presents ENEM abilities matrix related to Anderson and Krathwohl (2001) revised taxonomy.

Figure 5: ENEM Abilities matrix related to the cognitive domain of revised taxonomy according to Anderson and Krathwohl (2001).



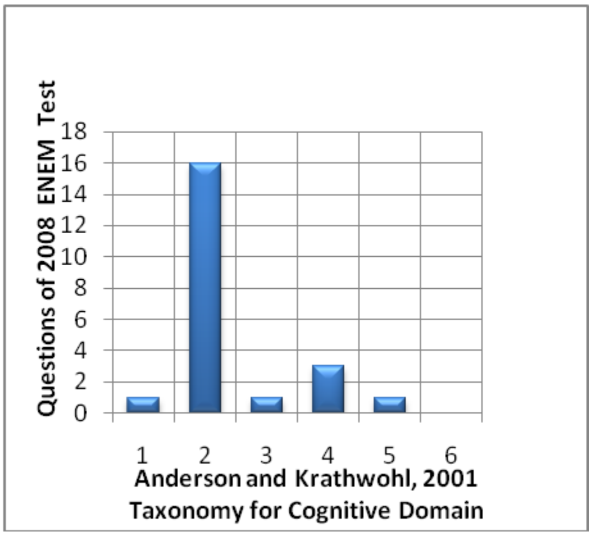
Many state tests prior to ENEM used the three basic levels of Bloom's taxonomy for cognitive domain. Our results showed that the matrix is not based on the three basic Bloom's levels since there are more than 10 questions on higher order thinking levels. Figure 6 shows 2007 ENEM Test considering Anderson and Krathwohl (2001).

Figure 6 – Questions of 2007 ENEM Test considering Bloom's Taxonomy revisited by Anderson and Krathwohl (2001)



Observe that even if the matrix presented five levels of cognition, the test itself presented only four. Level one questions did not show up on the matrix, but could be found on the test. On the other hand, level five questions appeared on the matrix but not on the test. The first level is not even considered a reasoning level, because it is only centered on information memorization. ENEM test claims it is not based on memorization, it is based on reflection. However we can see in Figure 6 that most of the questions (16 out of 26, considering levels 1, 2 and 3 of taxonomy) are distributed on the low reasoning level (Anderson and Krathwohl, 2001). Figure 7 relates 2008 ENEM test and Anderson and Krathwohl (2001) Taxonomy for cognitive domain.

Figure 7 – 2008 ENEM test considering Anderson and Krathwohl (2001) Taxonomy for cognitive domain.



As for the 2008 test, it seems that the level of reasoning is worse than the year before. It also shows that the test is not based on lower level categories of the revised taxonomy, however, there were 16 questions on the same level.

In a general sense, questions were intended to test students' reading comprehension. There were no questions to test previous knowledge, history and philosophy of Science or scientific discourses and practices. These results seem to be very relevant for Policy makers.

FINAL CONSIDERATIONS

This study aimed to investigate the Brazilian High School ENEM test. Major findings are:

- The total absence of History and philosophy of science.
- The almost non-existence of Inquiry approach of the questions.
- The lack of discussion about scientific discourse and science political view.
- The lack of correlation between test matrix and questions.
- The primary focus of the questions on reading comprehension.

This reveals that test writers should pay more attention to what is really important or fundamental in Science Education as mentioned by the NRC report (2007). Additionally, it was impressive to discover that even if the test is not following Bloom's Taxonomy (1956) or the Anderson and Krathwohl (2001) revisited taxonomy, it is clear that most of the questions are testing only reading comprehension contrary to what it should be doing. It seems National policies are not being followed by the question makers. We understand that people who are involved in test preparation should try new perspectives that could reveal students conceptions as a way to negotiate meanings among different cultural perspectives Mortimer (2004). It is our general perception that questions that test comprehension and analysis did not present a cultural perspective and this should be changed.

ACKNOWLEDGEMENTS

We are thankful to CAPES/INEP/SECAD that gave financial support to this study. And we appreciate the English language comments by Harriett S. Stubbs and Dee Wilson Davis.

SCIENTIFIC LITERACY FOR CITIZENSHIP: USING INTERLOCKING NARRATIVES AS A RADICAL PERSPECTIVE

r.levinson@ioe.ac.uk

ABSTRACT

In this article, we interrogate the aims of scientific literacy for citizenship, introducing socio-scientific issues (SSI) in science lessons through 'interlocking narratives'. In the humanistic writings of Paulo Freire, dialogical action theory enables actors to co-operate in transforming their conditions, both material and metaphysical. From a Freirean perspective, science pedagogy involves consciousness-raising about social injustice, such as the large numbers of people living in landfill sites, and developing the means to transform that reality. Stories, in the form of interlocking narratives, consist of a sequence of events which enable the linking of scientific concepts to issues of social justice, economics, environmental protection and employment. We illustrate through the life-cycle of an aluminium can how scientific processes interweave with socio-political events to make transformation of life conditions possible and we give some examples of narratives found in the "Chemistry and Society" textbook. These point to both contradictions and opportunities and hence offer a means of contemplation for dialogic action. However we argue that directed teaching of political literacy is a necessary adjunct to the teaching of socio-scientific issues.

Keywords: *Paulo Freire, socio-scientific issues, interlocking narratives.*

INTRODUCTION

The Brazilian philosopher, politician and educator, Paulo Freire, is perhaps best known for his book, Pedagogy of the Oppressed (Freire, 1972). Freire's work has been hugely influential in Latin America in adult education but it also offers insights into pedagogy in developing scientific literacy in a socio-political sense (Roth & Barton 2004). Drawing his critical theory from Hegel and Marx, Freire adopts a dialectical approach towards understanding nature. As opposed to the view which objectifies consciousness, consciousness itself is moulded from reality (Freire, 1996). Through dialogue men and women can transform their conditions because words and action underpin praxis, enabling the naming of the world and providing the means for its transformation.

Some of the work emerging from Science, Technology and Science studies has much in common with Freire's analysis, particularly work which re-visions scientific literacy and raises questions of socio-political action (Hodson, 1999; Roth & Calabrese Barton, 2004; Roth & Desautels, 2002). From a Freirean analysis science education becomes endowed with a radical perspective (Santos, 2009). This perspective involves reflections on inequitable living conditions from science and technology issues related to Freire's ideas. Santos (2009) presents a pedagogy of science education which could be formulated in the following steps: (1) identifying social issues for discussion; (2) establishing dialogue in the classroom; and (3) student discussion and engagement in socio-political action (this might, for example, involve generating political pressure on the local authorities to consider alternative landfill schemes which offer decent employment and sanitation conditions.

The narrative story is a useful instrument in initiating and providing objects of reflection for dialogue. The word 'narrative' has its roots in Latin and Sanskrit, *gnarus* (knowing or wisdom) and the Latin *narro* (relate or tell). In medieval times, *joculatores*, which forms the Latin root behind the English word 'joke' and the Spanish word 'toy', were popular street storytellers; there are elements of street credibility and frivolity. Narrative conveys what is known, and can take various forms – drama, saga, story, picture, cartoon, tapestry, film, epic poem, song. As well as allowing people to tell and listen, to talk of experiences not understood or imagined by others, narrative is an organiser for these experiences by sequencing events. It can be seen as:

> *. . . the outcome of a mental process which enables us to excise from an experience a meaningful sequence, to place it within boundaries, to set around it the frontiers of the story, to make it resonate in the contrived silences with which we may precede it and end it.' (Rosen, 1987, p.13)*

The Oxford English Dictionary definition of narrative gives 'an account of a series of events, facts, etc., given in order and with the establishing of connections between them' (Oxford English Dictionary),

Traditionally narrative has been conceived as a storyline consisting of a sequence of events. In foregrounding human consciousness. Fludernik (1996) emphasizes 'the representation of experientiality' (p.28) rather than temporal sequentiality. Experientiality can include a temporal sequence of events but this is not crucial to a portrayal of narrative dynamics, what is central is that '(h)uman experience typically embraces goal-oriented behaviour and activity, with its reaction to obstacles encountered on the way' (p.29) incorporated in a three part schema of 'situation – event (incidence) – reaction to event.' But the narrator is also a reflector of experience stored as 'emotionally charged remembrance' (p.29) and therefore the narrative becomes self-evaluative and 'accountable for the actions and experiences which compose a narratable life' (MacIntyre, 1981).

A model of narrative can be construed as consisting of Fludernik's three part schema which is reflected on by the protagonist as purposeful agent (or the protagonist acting vicariously) from a moral and ethical, in other words a values, perspective.

Where there are different kinds of equal but distinct reasons for actions and decisions by contending parties, narrative allows people to relate and listen, to tell of experiences not yet known, understood or imagined by other parties. Alternative courses of action can thus be illuminated, and within settings which contain the mainstream and the marginalised, allows stories to be told where other means of communication – the judicial court, the committee of experts, the competitive debate – constrain what is recounted. Reciprocity or mutual respect are thus presupposed in actuating narrative. Narrative is one of two modes of thought in reflecting experience (Bruner, 1986). The logico-scientific mode deals in general causes and their establishment and tests for empirical truth. The means by which these two modes can be used to convince are different, one seeks to appeal to procedures for establishing formal proof, the other through verisimilitude, providing narrative stories of lifelikeness (Bruner, 1986), the former seeking to *explain*, the latter to provide a means of *interpretation* (Bruner, 1996). But both are ways of structuring experience.

Through the deployment of particular protagonists it becomes possible to envisage how alternative actions lead to different consequences, some liberatory, some oppressive; even liberatory actions might have adverse implications for other communities.

Consistent with this approach is the use of narrative as a resource which enables identification of socio-scientific issues and the opportunities to seed dialogue. As a tool narrative:

> *has the power to make us see the lives of the different ... with involvement and sympathetic understanding, with anger at our society's refusal of visibility. We come to see how circumstances shape the lives of those who share with us some general goals and prospects. (Nussbaum, 1997)*

PAULO FREIRE'S IDEAS

Freire first developed his political philosophy among rural peasant communities and the urban poor of Brazil, and later, in Chile and in African countries. The basis of his educational thought is anthropological and it is addressed to oppressed people for ontological, epistemological and ethical reasons. We cannot understand his proposal if we do not take into consideration the context of oppression in the Third World.

The most important contribution of Paulo Freire's books and of his practise were to make people believe that it is possible to change the capitalist exploitation framework. He designed a philosophy which considers knowledge as a product of humane practises that result in the transformation of the world by the consciousness of the students. This occurs when they can understand through learning how they are being exploited through capitalism. The education process needs to be carried out from the social and cultural context of the students in such a way that the teacher can generate discussion from the teaching content to comprehend power relations in society. Freire (1974) states: 'To be human is to engage in relationships with others and with the world' (p. 3). From this engagement students can understand the exploitation process.

As a consequence education must consider the world in which man and woman exist, what it means to understand the inequality of power and the life conditions around different social classes.

In this sense, his proposal was initially developed for the context of the political oppression in Brazilian society at the time. He supported the idea that education, in Brazilian society, characterized by oppression, needed to help people enter the historical process critically (Freire, 1972, 1974, 1976). To accomplish this basic task, a form of education that enabled people to reflect, by themselves, on their responsibility and on their role in the new cultural climate (Freire, 1974) was called for. This new cultural climate would be a process in which instead of oppressed people silently accepting, a determined mode of being from the dominant capitalist class, i.e. the oppressors, they became political activists. Since Brazilian society at that time had all the characteristics of a 'closed society' in an alienated cultural context, in which the political decisions were take only by the elite, it was necessary to create an educational process as a practise of freedom that was supported by the pedagogy of the oppressed and aimed at changing the context of alienation and oppression.

The basis of his ethical and political educational theory is the contradiction between the oppressors and the oppressed. One can exist only in the presence of the other. Therefore, the principle of the education for freedom is that the oppressed cannot be developed from the oppressor's values.

Freire adopted a dialectical approach toward understanding the world, establishing a relation between consciousness and the world. Consciousness, according to Freire (1972), is created from reality. Taking into consideration that the world is unfinished and knowledge is dialectical, Freire (1972) states that knowledge is constructed and it can transform the world. In others words, instead of the 'closed society' which does not give opportunities for oppressed people to participate in it, Freire (1972) supported the idea that the educational process for freedom could transform this situation.

The basic principle of his pedagogy is dialogue. Freire (1972) said that education for critical consciousness should be developed through a dialectical process, which involves dialogue among individuals. It is by way of dialogue that man and woman are humanized. Words are not a mere expression of thought; they are a transformation of praxis, which acts upon the world. 'It is in speaking their word that (people) transform the world in naming it, dialogue imposes itself as the way . . .' in which human beings achieve significance as members of a common humanity (Freire, 1972, p. 61).

Whereas in the domination process the subject conquers another person and transforms him into a 'thing', the dialogical process has a dialectic feature in that one does not annul the other, as it occurs in the 'banking' educational process explained below. According to Freire (1972) in the dialogical process, subjects meet in cooperation to transform the world.

> *The dialogical "I", however, knows that it is precisely the "thou" ("not-'I'"), which has called forth his own existence. He also knows that the "thou", which calls forth his own existence, in turn, constitutes an "I", which has in his "I" its "thou". The "I" and the "thou" thus become, in the dialectic of these relationships, two "thous" which become two "Is".* (Freire, 1972, p. 135)

Dialogue does not impose, does not manipulate, does not tame. It unveils reality. In cooperation, the dialogic process focuses on reality that, posed as a problem, challenges the persons. It is opposed to the education made by the oppressors, which Freire (1972) called 'banking' education:

> *Education thus becomes an act of depositing, in which the students are the depositories and the teacher is the depositor. Instead of communicating, the teacher issues communiqués and "makes deposits" which the students patiently receive, memorize and repeat. This is the 'banking' concept of education, in which the scope of action allowed to the students extends only as far as receiving, filing and storing the deposits. They do, it's true, they do have the opportunity to become collectors or cataloguers of the things they store (p. 45-46)*

Accordingly, anybody educates anybody: man and woman are educated by each other, mediated by the world (Freire, 1972). For him, educating for literacy is more than a mere act of teaching to read and write. Humanistic education goes beyond teaching contents without social meanings. It focuses on the human condition and on its transformation.

He designed a revolutionary adult literacy proposal, which was very successful around many Third World countries. This proposal is comprised of three stages: 1) an investigative and preparatory work in order to identify the learners' social situation and to prepare materials and agendas; 2) a discussion of the learners' existential situation by analysing generative words and a series of pictorial representations of their adult culture; and 3) a syllabic combination by using generative words, starting with the reading of the words and the construction of new ones, continuing, however, the literacy process integrated with an exploration of contexts from which generative words emerged (Freire, 1976). These stages can be summarised as: reading of the world, sharing the world with others, and constructing and reconstructing the world. To read the world, we need to start with their cultural needs, and the learners need to have an epistemological curiosity. For Freire, human interest comes before knowledge. To share the world, knowledge needs to be mediated by a dialogical process. In this stage, culture is analysed from the generative words and pictures. This is a stage in which students develop a codification and de-codification process of the world. In the last stage, the world is constructed and reconstructed. Students learn to read and write the new words and discuss the actions to engage in the transformation of the existential situation around the generative words. For instance, from the generative word favela (slum), the problems regarding housing, health, food, and education are debated with student groups.

In this educational process, students develop an awareness of their situation, which is a political agenda. Freire firmly believed that education could not be neutral; that learning never takes place in a vacuum (Freire, 1972, 1994). In fact, those who believe that the teacher has to be 'apolitical' are unintentionally and naively supporting the dominant ideology imposed by technological systems. They reinforce it when they do not discuss it with their students. In this respect, Freire postulates:

> *The very nature of the educational practice – its necessary directive nature, the objectives, the dreams that follow in the practice – do not allow education to be neutral as it is always political… The question before us is to know what type of politics it is, in favor of whom and what, and against what and for whom it is realized. (Freire, 1993, p. 22)*

In conclusion, the humanistic science educational in the Freire's view requires that the educator to have a commitment toward social change, taking into account larger global concerns, focusing on equity and social justice (Santos, 2009). These political agendas have been proposed for science education (e.g. Barton et al., 2003; Barton & Tobin, 2001, 2002; Elmesky & Tobin, 2005; Roth & Barton, 2004).

In this way, we can use Freire's ideas to construct a radical perspective towards scientific literacy for citizenship, introducing socio-scientific issues (SSI) in science lessons through 'interlocking narratives' as we discuss next section.

INTERLOCKING NARRATIVES

Using the idea of interlocking narratives, Levinson (2009) shows how chemical concepts such as the reduction of aluminium ions in the manufacture of aluminium, are interconnected with the spoliation of sites of natural beauty, opportunities for recycling, initiating social justice programmes for rubbish-pickers in Brazilian cities and threats to employment for workers in Jamaica (Figure 1).

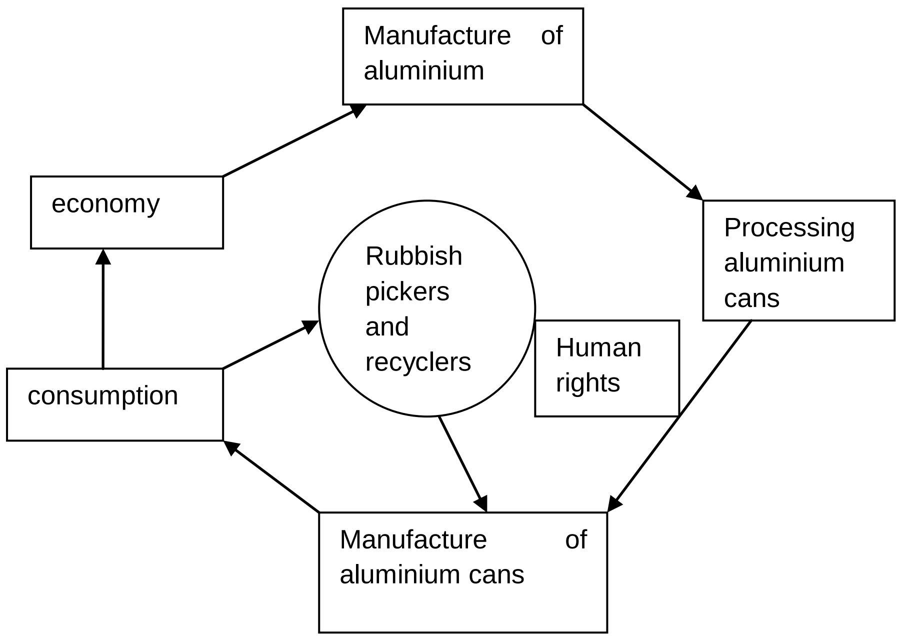

Figure 1: A cycle of linked events between the manufacture of aluminium, street-recyclers and their human and political rights.

Hence in figure 1, the manufacture of aluminium from bauxite involves a huge consumption of energy often provided by hydro-electric power stations which damage areas of natural beauty. The aluminium is processed for the manufacture of drink cans. However, Brazilian urban rubbish pickers, the *catadores de lixo*, recycle the cans. This has a number of effects which have transformed their lives. Recycling reduces the necessity for aluminium manufacture and the *catadores*, through unionising, have gained sufficient political power to transform their own lives and gain important human rights such as housing and schooling.

These stories then become teaching opportunities in identifying conditions of oppression and discussing resulting action. There are many different themes in science and technology with lend themselves to this kind of approach. For example, the role of tea-gatherers in East Africa or Palestinian farmers dependent on water in conflict situations, the technology underpinning a genetic test kit and its social implications, community action in rebutting the patenting of the Neem tree (Shiva, 2001).

Examples of narratives are also found in the textbook *Chemistry and Society* (Santos et al, 2005), developed for Secondary Schools by the *Chemistry and Society Teaching Project* in Brazil. In this textbook topics are driven through stories of justice and social equity from science and technology, for example the life condition of workers in landfill sites can be studied through an understanding of properties of matter and separation methods, and differential and inequitable access to foods around the world from the study of agriculture and chemistry.

The texts that incorporate narratives establish links with chemistry concepts and political issues to be discussed by students (Santos et al, 2006). The political issues are introduced from poems, pictures and questions about the technological conditions around the world. Activities to engage students in political action in communities are suggested in a special section of the textbook.

CONCLUSIONS AND IMPLICATIONS

From Freire's ideas scientific literacy has a radical perspective in transforming society towards justice and social equity. We suggest in this paper that the humanistic science education in this radical view can be carried in science education from socio-scientific issues, which could be introduced by teaching through interlocking narratives.

The use in science education of interlocking narratives interconnected with social issues could empower political discussions. However, implementation in the classroom is problematic. Teachers can lack confidence in raising these issues and managing discussions (Levinson & Turner, 2001, Levinson, 2001, Bryce & Gray, 2004) and schools themselves often operate under undemocratic conditions which stifle possibilities of action (Flutter & Rudduck, 2004). One possible approach is through directed teaching of political literacy (Ruitenberg, 2009) congruent with dialogic action which makes political options both explicit and realistic. Identifications of contradictions inherent in these interlocking narratives can become a focus of discussion in classrooms and among teachers, and even seemingly insignificant actions such as the implementation of fair-trade products in school demonstrate how dialogue can be transformed into action. Mapping discussions and associated actions through dialogic action anticipates future research initiatives.

ABSTRACT

Studies focusing on environmental education and continuing education of science teachers play an important role in the science education area. This research analyzed conceptions of environment in a continuing education course for science teachers developed at the University of Sao Paulo, Brazil. The analysis of the material was made using a qualitative approach and content analysis methodology. The conceptions of environment were analyzed and characterized by the use of categories previously defined and selected from the literature. Although different conceptions were identified, the conception of environment as a resource prevailed, demonstrating a serious limitation of the course in the environmental education of the participating science teachers. As a result of the training process, a naive and limited view on environment by teachers was observed. The results point to the need to reformulate continuing education courses in order to favor a more critical environmental education.

Keywords: *environment, science teacher, continuing education.*

INTRODUCTION

Over the last decades, science education research has been preoccupied with the way science is associated with ethical, political and social aspects. In this context, studies focusing on environmental education and continuing education of science teachers play an important role in the science education area.

Kuhn (1980) and other researchers have shown the importance of in-service training for science teachers to keep abreast of changes in their field in subject matter, curriculum development and instructional techniques. Aleixandre & Gayoso (1996) present an approach that attempts to use environmental education as a thread in scientific methodology courses intended for teacher education. In Brazil, an overview on science teacher education has been recently published (Villani et al., 2009). It analyzes the most significant events that have been occurring in Brazil's educational, social and political areas over the last half century, in comparison with a set of relevant worldwide events.

A clear understanding of the concept of training and the analysis of conceptual frameworks related to professional teaching conditions are fundamental to understanding the training process in which teachers are involved. Based on the classification of paradigms of Zeichner (1983), conceptual guidelines of Feiman-Nemser (1990) and the classification of Pérez Gómez (1998), Garcia (1999) proposed five types of teacher education orientation: academic, technological, personalist, practical, and social reconstructionist.

In the academic orientation, continuing education is seen as a process of transmission of scientific knowledge and culture, by means of a specialist training. In the technological orientation, education is seen as an applied science and the teacher as a coach who dominates the applications of scientific knowledge produced by others and transformed into rules of action. The personalist orientation believes that each person develops their own strategies to become a teacher, occupying the main role in teacher training to achieve personal development training. The practical orientation is found in the organization and development of teaching practices, and it valorizes learning from experience. According to that perspective, practical experiences contribute to providing teachers with better training, because they combine observation, direct experience and interrelationships with more experienced colleagues. The social reconstructionist orientation is an ethical and social reflection, seeking the ability to analyze the social context. In this orientation, teacher training is directly related to processes of change, innovation, and curriculum development for teachers, who are considered as individuals committed to the principles of social justice and democracy.

The characterization of the environmental approach in a particular educational context is generally thought considering the analysis of environmental education (EE) expressed in the context analyzed. From this perspective, a lot of research has been developed, identifying different conceptions of EE and proposing different categories to illustrate the form of ownership and the meaning assigned to that expression. As a result, a significant number of categories associated with the concept of EE are generated, whereupon there is a diffusion of meanings attributed to that expression.

This tendency of researches to identify the perceptions and meanings of environment and EE is pointed by several studies available in the literature. Parallel to these studies, other researches have been carried out aiming to characterize different conceptions of environmental education and environment in order to understand the different forms of ownership of these issues.

Sauvé (2005) proposes seven ways of apprehending the environment: as nature, as a resource, as a problem, as a system, as a place to live, as the biosphere, and as a community project. These categories are based on the understanding that environmental education can be understood from our relationship with the environment. Considering the importance of environmental education in teacher training, this research focus on the identification and analysis of the conceptions of environment expressed in the materials produced in a continuing education course occurred at the University of Sao Paulo – Brazil, assuming the environment as a key concept to the consolidation of a process of continuing education committed to an effective environmental education. This research leads us to the understanding of different forms of ownership of environmental issues in these courses, often presented as a challenge for the construction of a critical, complex and reflective thinking (Jacobi, 2005), as needed for the construction of teacher identity (Pimenta, 1999).

METHODOLOGY

This research analyzed conceptions of environment of a continuing education course for science teachers developed in 2006 at the University of Sao Paulo, Brazil. Such conceptions were identified through documental analysis of all material related to the course, including the basic guidelines proposed by the Sao Paulo government, the formal pedagogical project produced by the University of Sao Paulo, and the teachers' productions.

The analysis of the documents was made using a qualitative approach and conceptual analyses based on content analysis methodology in accordance to Bardin (1997) and assuming that words mentioned more often are those that reflect the form of ownership of important concepts in the documents examined.

Two types of units of analysis were used: sampling units and context units. Specific parts of content were selected as sampling units, and the analysis revealed the frequency of the terms listed in the table 1, all of them directly associated with the idea of environment.

Table 1 – Terms directly associated with the idea of environment that were used in the research in order to characterize the conceptions of environment.

Terms directly associated with the idea of environment
Environment(s)
Natural environment
Environmental
Socio-environmental
Sustainable development
Sustainability
Sustainable society
Nature

The set of terms related to conceptions of environment was built based on the researcher-object interaction and on exploratory readings of all the material analyzed.

Regarding the context units, not only their frequencies were analyzed, but also the contexts in which they occur. Annotations, tables, diagrams, and other sorts of brief communication were all used as sampling units, being part of the first stage of data classification, which also included the type of information source, the topics and themes addressed, and the nature of the material collected. After all the material was read and the data organization was completed, some categories of analysis were created based on the fact that, according to Bardin (2000), such type of categories can classify the elements of a group by means of differentiation and then regrouping, taking into account previously defined criteria. The information was grouped considering the terms with regular frequency expressing conceptions of environment that were associated with the categories proposed by Sauvé (2005), which are listed in the table 2.

Table 2 – Categories of environment used for the classification of conceptions of environment expressed in the material analyzed.

Categories of conceptions of environment*
As nature
As a resource
As a problem
As a system
As a place to live
As the biosphere
As a community Project

* Proposed by Sauvé (2005).

As soon as an initial set was obtained, the categories were assessed regarding their range, diversity, and limit. The idea was to identify the main environmental education (EE) perspective present in the course based on the dimension of the ownership of conceptions of environment.

The course analyzed was organized for the “Web of Knowledge” Program, focusing on educational topics related to science teaching and deepening themes of Science, in order to promote instructional transpositions and/or recontextualizations of scientific knowledge to the school context.

From the conceptual and methodological approaches of subjects of natural sciences, the teachers created thematic projects (TP) as a joint proposal between teachers from the same school or between teachers from different areas in order to encourage interdisciplinary collective actions in school after the continuing education course. In these projects, the participating teachers had the opportunity to carry out the planning and preparation of schedules of courses and teaching sequences on the theme, taking an active role during the course. The group of teachers consisted of people in the age range of 30 to 55 years, the majority of them (71.4%) being women. Their teaching subjects included Mathematics, Physics, Chemistry, Biology, and Science. In this regard, it should be pointed out the considerable amount of Biology teachers (33.33%) and the fact that 80.95% of the teachers were assigned to teach subjects related to only one knowledge area.

RESULTS AND DISCUSSION

Conceptions of environment in the basic project of the Sao Paulo government

It was observed that the term environment appears in the basic project of the Sao Paulo government with the meaning of place, associated to the context of learning environment. Nature was another term identified as a possible environmental focus. However, it is only used to characterize an area that includes some scientific knowledge. In both cases, there is not an explicit ownership of the concept of environment, which demonstrates the absence of environmental education in the basic guidelines established by the Sao Paulo government for continuing education programs designed for science teachers.

The basic project proposes the use of new methodologies focused on innovative practices and use of instructional materials. The training of teachers is focused on the development of skills for the use of new technologies with the adoption of assessment practices as a monitoring tool of teaching, emphasizing the development of skills in a continuing education based on technological orientation, as defined by García (1999).

Conceptions of environment in the pedagogical project of the course proposed by the University of Sao Paulo

As in the basic project, the term environment appears in the pedagogical project of the course with the meaning of place, referring to school as a place of learning situations. It is established that the environmental approach should be treated as one of the themes to be developed, but no explicit conception of environment is provided.

The absence of an environmental perspective for continuing education can be explained by the need for coherence between the pedagogical project proposed by the university and the one proposed by the Sao Paulo government, resulting in a repetition of several parts of the basic project of the government. In this regard, the pedagogical project can be considered as being only a bureaucratic and formal document without a detailed description of its real pedagogical intentions.

Unlike the basic project of the government, the pedagogical project of the course shows a strong academic orientation, focusing on specific scholar contents related to natural sciences. A practical orientation in a reflective approach (Pérez Gómes, 1992; Schön, 2000) is also observed, showing the concern of reflecting on the practice itself, involving all teachers in reading activities and records of texts. It is important to note that in both documents the absence of an environmental perspective is due to the emphasis on a continuing education with technological, practical and academic orientation.

Conceptions of environment present in the materials used by teachers during the course

The frequency of terms related to environmental issues present in the materials used by teachers during the course is shown in Table 3. It is observed that the terms environment and nature appear with more frequency in most of the materials analysed. However, it was not possible to clearly identify conceptions of environment using the categories proposed by Sauvé. This result suggests that there is not a prescription of a conception of environment present in the materials used by teachers in the course.

Table 3 – Frequency of terms related to environmental issues present in the materials used by teachers in the course.

Conceptions of environment in thematic projects produced by teachers

The frequency of terms related to environmental issues is presented in Table 4.

Table 4. Frequency of terms related to environmental issues present in thematic projects produced by teachers.

Thematic projects	EN	SE	SD	S	SS	N
TP1	2	0	0	0	0	0
TP2	1	0	0	0	0	0
TP3	6	0	0	0	0	0
TP4	0	0	0	0	0	0
TP5	6	0	0	0	0	1

EN: Environment; SE: Socio-environmental; SD: Sustainable development; S: Sustainability; S: Sustainable society; N: Nature

The term environment was the most cited among the six terms used in the analysis of frequency. Only the thematic project TP4 did not make use of a term explicitly associated with environment.

In TP1, teachers point out that

> *"The theme of global warming was chosen because of the drastic consequences that the planet will suffer in the future, as well as because it integrates related disciplines and can be linked to the social, political and environmental... This theme sends an alert to young people (students) about the problems that may arise".* (TP1)

In TP1, the contents of the curriculum components are seen as knowledge to be acquired to minimize or solve future problems, which is characteristic of a conception of environment as a problem to be solved. However, the analysis of the other thematic projects produced by the participating science teachers shows the predominance of the conception of environment as a resource (Table 5), illustrating a serious limitation of the course in the environmental education of science teachers.

Table 5. Conceptions of environment in thematic projects produced by science teachers.

Thematic project	As nature	As a resource	As a problem	As a system	As a place to live	As the biosphere	As a community project
1	-	-	X	-	-	-	-
2	-	X	-	-	-	-	-
3	-	X	-	-	-	-	-
4	-	X	-	-	-	-	-
5	-	X	-	-	-	-	-

X= symbol indicating the presence of the conception.

In relation to the conceptions of education, the TPs produced by the teachers favor a practical perspective within a reflective approach. However, in the pedagogical project there was no emphasis on a technological and academic orientation.

These results indicate a possible correlation between a conception of environment as a resource and a practical approach, pointing to the need to reformulate continuing education courses in order to favor a more critical environmental education.

The incorporation of environmental issues in the educational process should include, as a first step, the involvement of the teacher, who should be aware of the need for this issue and then prepared and equipped to meet this challenge. We agree with Carvalho (2001) when he points out that it would be imprudent to reduce certain arrangements. The institutions responsible for education, along with other social sectors, should provide different educational opportunities for in-service teachers in order to ensure their continuing education.

Considering the different dimensions in teacher education proposed by Carvalho (2001), we understand that the course analyzed should explore more the dimension related to ethical and esthetic values and other initiatives that favor a more effective political participation of citizens.

ACKNOWLEDGEMENTS

P.B. thanks CAPES and CNPq (Brazilian agencies) for a graduate fellowship. We also thank Nídia Nacib Pontuschka and Filomena Elaine Paiva Assolini for comments that greatly improved the manuscript.

HOW TO MAKE TECHNOLOGY INTERESTING TO PUPILS?

Ivan Dović

OŠ Brinje Grosuplje (Primary School Brinje Grosuplje) / primary school teacher

ivo.dovic@gmail.com

ABSTRACT

In this presentation I will talk about my idea of making technology interesting to pupils aged between 11 and 14. During the nine years of my professional practice I have developed a successful method, stimulating the interest in technical subjects on our school to a high level. During my lessons I encourage pupils to gain knowledge through their own experience; therefore I always organize work according to the project learning method. I make sure that projects are interesting and entertaining to pupils and I try to include the largest possible number of aims, determined by the national curriculum. Such working method has proved to be successful- in school year 2009/2010 approximately 20% of pupils applied for model making class as one of extra-curricular activities at our school and 25% of pupils in the Years 7, 8 and 9 decided to take elective technology subjects. I will present two projects realised during the lessons of Design and Technology in Year 7 and model making class.

Keywords: *project learning method, curriculum, aims, electric car, eco speed boat, plastic, composite materials, fibreglass, electric motor*

INTRODUCTION

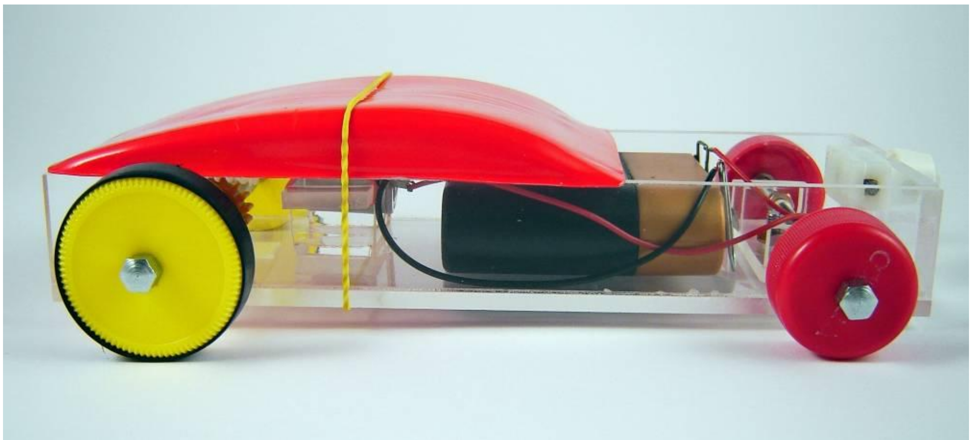
In recent years Slovenia has been facing a problem of an alarmingly small number of technically educated workers, who are able to create innovative and technologically perfected products with high added value. But on the other hand in the last primary education reform (introducing nine-year primary education system) the number of lessons intended for school subject Design and Technology was reduced by almost 50 percent. Such obvious paradox encouraged me to establish my own, and for some debatable, teaching concept. I no longer blindly follow the national curriculum in achieving every written aim. Such teaching practice allows only less active interaction patterns (whole-class teaching, power-point presentations, etc.) Apart from this the achieved aims are assessed with the National Assesment of Knowledge. This consequently encourages the above mentioned forms of interaction, which ensure a “successful” input of knowledge.

I believe the mission of a primary school teacher is not only to extend certain knowledge, which is sadly too often obsolete, but also to enable pupils to witness and actively engage themselves in numerous areas of design and technology. If a teacher succeeds and sparks the interest of pupils for technical subjects, he/she has to be able to encourage a pupil to seek further information and knowledge. A teacher should also trust a pupil will eventually master such knowledge and improve it.

Sadly, I have noticed that Slovenian teachers prefer to realize more traditional contents and try to evade demanding topics such as electronics and robotics. Teachers should be competent enough to create optimum conditions and enable pupils to learn about these topics through their own experience and not just theoretically. Pupils learn more effectively when they are successful at their work and it is a teacher's responsibility to plan activities which make this possible.

When I plan lessons I always keep in mind that pupils must gain knowledge through their own experience. At the end of every project pupils make their own products and I try to include the largest possible number of aims determined by the curriculum during the making. In the following paragraphs I will describe two projects- the first one was carried out during the lessons of Design and Technology in Year 7 and the second one during the model making class.

THE MAKING OF AN ELECTRIC CAR MADE OF PLASTIC MATERIALS



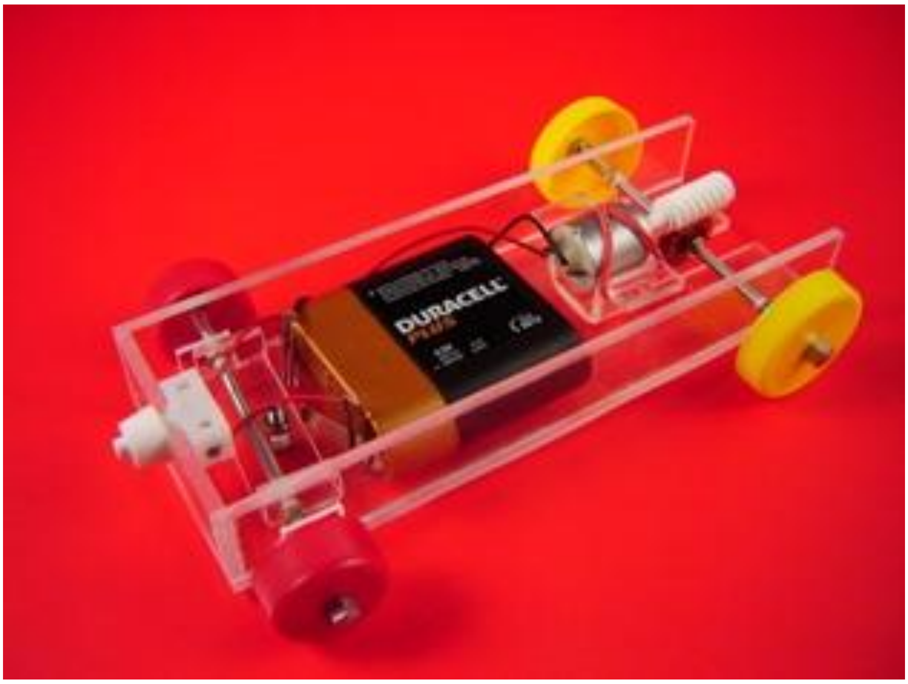
Picture 1.

During the lessons of Design and Technology in Year 7 pupils assemble an electric car made from plastic (Picture 1). The making of the car includes the most important curriculum goals and contents of Year 7: synthetic materials, electricity, motion transfer mechanisms, computer control, technical drawing and ecology.

The aims of the curriculum content Technical drawing are achieved in a phase of designing the car. Pupils draw plans of the car with a computer programme Cici-Cad and learn the basic rules of computer aided design.

Car body is made from two different synthetic materials. Acrylic glass is used for the car's understructure. During the making of the car pupils discover basic characteristics of acrylic glass (it softens when heated, its soft surface is sensitive to mechanical damage) and its basic manufacturing procedures - sawing, grinding and drilling. Apart from this they use a more demanding procedure- thermal transformation. The top of the car is made from polystyrene, another thermoplastic, which softens when heated. In order to make the top part pupils reshape polystyrene with a technique called deep drawing.

The car is powered by an electric motor. Pupils have to wire it up into a closed electric circle with a switch and a source of voltage. At this point pupils learn that the electric motor functions as a consumer and the battery as the power source. We also discuss other sources of electric energy and debate whether they are suitable for the car.



Picture 2.

In addition, pupils are presented with the possibility of changing motor's spinning direction with two switches and encouraged to think about a different use of switches in an electric circuit (logic gates).

In the next step pupils have to create a motion transfer from the motor to powered wheels with worm and spur gears. They discover that the motion transfer is possible only from the worm gear to the spur gear and that this gear pair changes the axis' direction of spinning and reduces the number of spins. Pupils also debate whether the number of spins could be changed in any other way.

The making of the car is also an excellent opportunity to think about the environmental problems, especially about the influence of synthetic materials on the environment. To contribute to a cleaner environment pupils reuse plastic bottle caps as wheels. Apart from this they also like to speculate about electric cars of the future.

The making of the car almost entirely fulfils the aims determined by the curriculum. Pupils find it interesting and they work enthusiastically through the whole process. Every June, during the longest break, pupils race their cars in our school's hall. The racers, as well as the spectators, find this event pleasant and interesting.

I sincerely believe that teachers should give careful consideration to the emotional component of teaching and learning when planning lessons.

The process of designing and making a product as well as learning new skills should be carried out in a relaxed and pleasant atmosphere. Thus pupils subconsciously perceive technology as something enjoyable and fun. These positive feelings will form their motivation pool and encourage further studies, research and work in the field of technology.

BUILDING A 3.5 METRE **LONG ELECTRIC SPEEDBOAT IN A MODEL MAKING CLASS**

Picture 3

In the second year of my teaching the pupils of a model making class expressed a wish to make a real sailing boat instead of usual model crafts. At first it was meant as a joke, but later we decided to face the challenge and in the same year built a 3 metre sailing boat (Picture 3). The project was a success in every possible aspect and from then on we have continued to undertake more complex projects.

In the following years we have built also a 2.5 metre long Space Shuttle and an electric car. Our most recent project has been developed for two years. It is a 3.5 metre long speedboat with an electric drive (Picture 3).

It was again the pupils who came up with the idea because they had grown tired of waiting for favourable winds to sail with a sailboat. In order to engage pupils at a maximum level a design competition was held at our school. Together with the members of the model making class we established that the traditional boat building methods are unsuitable. Therefore we searched for techniques manageable for pupils which would produce the results in a relatively short time.

Picture 4.

Picture 5.

We decided to make the speedboat out of 6 millimetre plywood and cover it with polyester resin and fibreglass (Picture 4, 5).

During the making the pupils learned many new woodworking skills (working with electric jigsaw and electric plane, bending wood). Furthermore, the speed boat was coated in polyester resin and fibreglass so the pupils also worked with composite materials used in boat and aircraft industry as well as in space technology. The pupils learned about mechanical engineering by planning and building in mechanical parts (they built in a motor, created motion transfer from motor to drive shaft, they built in a drive shaft, made it watertight and installed a propeller). One of the most demanding tasks was building in a steering mechanism, which has to withstand considerable forces. The making of the speedboat included also the knowledge of electronics. We had to wire the electric motor with an electric speed controller and a power source. Compared to this the wiring of a car radio and speaker was an easy task.

A detailed description of the speedboat's making is not necessary at this point. I believe I should emphasize the effects this project had on the pupils instead.

A remarkable success of this project is a consequence of the fact that it was the pupils who wanted to fulfil their dreams of building a speedboat. They spent their free time working hard and learning something new. The knowledge they gained is priceless because they acquired it through their own experience. A lot of mistakes were made but consequently the pupils showed a lot of creativity while searching for new, technologically improved solutions.

You are quite right if you think this project was time-consuming and technically demanding. A lot of skilled knowledge was required and I admit that at the beginning I had little idea what I was getting myself into. But my goal was to finish the speedboat together with the pupils and take a ride on a local pond. In the past two years I often had to search for solutions to technical problems. I believe that a teacher should continuously learn and search for new knowledge rather than to strive to know everything. The pupils learned that two heads are better than one and that one shouldn't run when facing a problem. One just has to work hard and search for solutions in all possible areas.

To sum up, we all learned a lot during this project. Being highly motivated for work we often stayed in the workshop after school and during holidays. We concluded our project with a successful public launch, considerable media coverage and we received a golden award at the national competition of young technicians.

You can learn more about the electric car, ECO speedboat and my other projects on http://www2.arnes.si/~idovic/

THE *CRAR3FS2* FRAMEWORK FOR DEVELOPING TEACHERS' *ICT* SKILLS FOR SCIENCE EDUCATION THROUGH CYBERHUNTS

André du Plessis

Nelson Mandela Metropolitan University, Port Elizabeth, South Africa

andre.duplessis@nmmu.ac.za

Paul Webb

Nelson Mandela Metropolitan University, Port Elizabeth, South Africa

paul.webb@nmmu.ac.za

ABSTRACT

This paper investigated the use of a cyberhunt approach on the promotion of the critical learning outcomes required of South African science teachers by the national curriculum. The focus of this paper is on how the teacher development process for Information and Communication Technology (ICT) integration by means of cyberhunts, should be managed. The case study was conducted within the interpretive paradigm and made use of qualitative and quantitative data gathering methods. The data generated suggested positive results regarding the perceptions of the participating teachers towards the cyberhunt strategy. The data suggest that the CRAR^{3}FS^2 model seems to be a successful framework to develop teachers for the cyberhunt Internet-based teaching and learning strategy. It is proposed that teacher-development facilitators should take note of the CRAR^{3}FS^2 framework when they plan and implement Internet-based teacher development sessions which teachers can implement as teaching and learning strategies within their classrooms.

Keywords: *CRAR^{3}FS^2 framework, Teacher development, ICT, e-Education, Cyberhunts, Internet, Science education*

INTRODUCTION

Learner performance in the annual South African grade 12 exit examinations has been generally and consistently poor for decades (Fleisch, 2008; Christie, Butler & Potterton, 2007; Taylor & Vinjevold, 1999), while the country attained last place in the Third International and Mathematics and Science Study in 1998, and in the Trends in Mathematics and Science Study in 2003 in both science and mathematics. These poor results have been attributed to many teachers' inability to stimulate attitudes of curiosity and critical thinking skills and their reliance on rote learning, memorisation and recall (Christie, Butler & Potterton, 2007; Taylor & Vinjevold, 1999). As such the training of teachers (both pre- and in-service) has been identified as a key aspect in implement the modern approaches envisioned in the latest South African national curriculum (Kallaway, 2007). However, there are a number of barriers to successful teacher development, which include teachers' lack of knowledge, skills and self-belief (Christie, Butler & Potterton, 2007).

The critical outcomes of the South African National Curriculum Statement (NCS) specify that learners should be able to (1) identify and solve problems by means of critical and creative thinking, (2) work together in teams, (3) manage themselves responsibly, (4) collect and analyse information, (5) communicate effectively, (6) use science and technology effectively, (7) see the world as set of related contexts, (8) employ effective learning strategies, (9) become responsible citizens, (10) be culturally and aesthetically sensitive, (11) explore education and career opportunities and (12) develop entrepreneurial abilities (Department of

Education, 2002). In the Science Learning Area, the curriculum attempts to address issues of developing scientifically literate citizens (Department of Education, 2002). The generative use of ICT via Cyberhunts is seen as one way of attaining these learning outcomes and to address the cognitive development of learners (Du Plessis & Webb, 2008). This paper, which forms part of a larger study on ICT in schools, reports on which aspects should be taken into consideration to develop teachers for successful ICT implementation of science created cyberhunts as an Internet-based teaching and learning strategy (Du Plessis, 2010).

CYBERHUNTS AND KNOWLEDGE AS DESIGN

A cyberhunt refers to an online activity where learners are using the Internet as a tool to find answers to pre-determined questions (Rechtfertig, 2002) based upon a certain theme or topic. These questions are usually on different cognitive levels, and teachers may use cyberhunts as an introduction to a theme in a pre-activity, as a review for an upcoming test or as another form of authentic assessment (Slayden, 2000). Cyberhunts can also be used as a knowledge generation tool when learners become cyberhunt designers (Du Plessis, 2010). Learners-as-designers of their own cyberhunts on a topic should be the ultimate goal in cyberhunt design for teaching and learning. This relates to the idea of knowledge as design (Perkins, 1986; Harel & Papert, 1990) where learners become designers or users of knowledge instead of passive consumers of knowledge, when they construct, compose, write by typing and investigate (Du Plessis, 2010).

The use of computer technology by learners to design artefacts in order to develop cognitive skills is not, in itself, a novel idea in education as illustrated by the research of Carver, Lehrer, Connell, & Erickson (1992); Lehrer, (1993), Lehrer, Erickson and Connell (1994) and Du Plessis (2004). However, learner created or learner designed cyberhunts is a novel idea, as learners not only become the designers, but they also compose questions on different cognitive levels about the topic(s) that they explore. Composing questions on different cognitive levels requires a significant preparation from the teacher's side as he/she has to introduce the learners to the different cognitive levels and to the different verbs which are associated with each level.

Research has shown that when learners design computer based artefacts by using the computer as a cognitive design tool (e.g. within a knowledge-as-design context), the major thinking skills that learners need to use as designers of these systems, include project management skills, research skills, organisation and representation skills, presentation skills and reflection skills (Lehrer et al., 1992; Lehrer, 1993; Lehrer et al., 1994; Liu, 2003, Du Plessis, 2004; Du Plessis, 2010). Each of these skills include various sub-skills, for example, research skills include reading, note taking, defining or creating keywords, validation of the quality of knowledge, search skills, and so on (Du Plessis, 2010).

Yore & Treagust (2006) argue that the focus of science curricula should be the development of learners' cognitive tools and their communication abilities in science. Hokanson and Hooper (2000) argue that when ICT is used in education, it should foster thinking. Hence, when one combines science and ICT in teaching and learning, the main emphasis should therefore be on enhancing cognitive abilities. We are of the opinion that teacher created cyberhunts and especially learner created cyberhunts, have the potential to enhance learners' cognitive and communication abilities in the science curricula when learners create science based cyberhunts. Our argument is based on the fact that when learners become the designers of cyberhunts and not mere users of pre-designed cyberhunts, it is possible for the 'learners-as-designers' to acquire Internet related skills, e.g. searching the Internet by making use of search engines, the identification and evaluation of the level and appropriateness of websites to be included for their cyberhunts and even enabling them to compose questions on different cognitive levels (Slayden, 2000; Rechtfertig, 2002). In addition, it is also important to note that the main focus of the learner-designed cyberhunts is on the design skills (Lehrer et al., 1992; Lehrer, 1993; Lehrer et al., 1994; Liu, 2003, Du Plessis, 2004).

The main difference between learner-created cyberhunts and other web based activities is the fact that in the learner-designed cyberhunt, the learners have to compose questions on different cognitive levels that their peers (or even other teachers) have to answer by exploring the provided hyperlinks. It is important to note that the composition of questions and memoranda by learners is not a key element in webquests and project-based learning web based activities. We are of the opinion that cyberhunts do have the possibility to generate thought as cyberhunts could become a learning tool for learners and even other teachers, as learners and teachers may utilise the learner-designed cyberhunts to explore a topic. Learners may therefore use the learner-designed cyberhunts to enrich their knowledge, to ameliorate understanding of a topic(s) with which they struggle and/or even to learn and discover at their own pace. Thus, cyberhunts could be used to move learners who struggle with certain aspects within the curriculum, through the Zone of Proximal Development (Du Plessis, 2010). It is therefore argued that the generation of thinking is precisely what could happen when learners answer the composed questions in a cyberhunt or when learners themselves compose questions when they design their own cyberhunts.

The dominant model of computer deployment and computer utilisation in South African schools is the computer room or laboratory where learners work individually and the main focus is computer literacy (Department of Education, 2002). ICT integration seems to be minimal (Department of Education, 2002). It is therefore imperative that other alternatives are explored that will change this situation (Department of Education, 2004). Cyberhunts is totally different from the dominant model, as computer literacy is not the main focus, but the generation of thinking is.

It is important to note that for learners to become designers, their teachers need the design skills required for cyberhunt construction in order that the teachers can empower their learners through a facilitation process to become designers also. This teacher development process would need careful planning, especially pertaining to composing questions on different cognitive levels, as the teacher would have to introduce the learners to the different cognitive levels and to the different verbs which are associated with each level (Du Plessis, 2010).

When learners compose their own questions for their cyberhunts on different cognitive levels about a topic that they explore, they are thus linking this to the identification of a question(s) as required for the development of scientific literacy (Webb, 2009). While the learners design their own cyberhunts either individually or in groups, they acquire new knowledge, they need to explain certain aspects, they have to determine whether the information is truthful and they can be afforded with reflection opportunities regarding their experiences during the design process by means of journal writing (Du Plessis, 2010).

TEACHER DEVELOPMENT

Staff development programs with respect to technology, should be (1) hands-on, (2) on-going, (3) providing staff with the technology equipment, (4) incentive driven, (5) should be reviewed regularly (Picciano, 2006) and should include reflection as a learning tool (Hoban, 2002). Lawless and Pellegrino (2007, p. 597) argue that professional development should have as its focus to assist teachers to change their pedagogies with a view to improve teaching and learning, hence they argue, the question professional developers have to ask is, “What do teachers do differently in their classrooms as a product of professional development?” Therefore, one should ask oneself when deciding on a specific teacher development model, whether this model will result in teachers changing their pedagogies.

We are of the opinion that learner-designed cyberhunts have the possibility to add to the pedagogic repertoire of teachers.

METHODOLOGY AND METHODS

The research formed part of a larger study that used quantitative and qualitative data gathering tools. The research project was conducted within the post-positivist paradigm (Niglas, 2001; Mertens, 2005) underpinned ontologically by a critical realist position (Sayer 2000; Benton & Craib, 2001) and epistemologically by a socio-cultural perspective (Vygotsky, 1978; Engeström & Miettinen; Roth & Lee, 2007). Qualitative and quantitative data gathering methods (mixed research) were used (Kelle & Erzberger, 2004; Johnson & Christensen, 2008) within an interpretative case study (Yin, 2003). Quantitative data gathering tools that had been used in the larger study; comprised of Likert scale questionnaires, a computer skills questionnaire, as well as certain quantitative sections within the semi-closed-open-ended questionnaires. The qualitative data gathering tools that had been used semi-closed-open-ended questionnaires, journal- reflection sheets, observation and interviews. The summary of the findings reported in this paper, is based on the qualitative findings.

THE INTERVENTION, ITS THEORETICAL BASIS AND ITS PHASES

Thirty-six teachers from six poorly resourced (both human and material) schools (four primary schools and two high schools) formed the convenience sample used in this study, as each of these six schools received 20 computers for free from the Dell Foundation. The project ran from March 2008 to the end of September 2008 with an average attendance of 27 participants per session.

This intervention that took place was informed by a community of practice framework embedded by cognitive apprenticeship (Brown, Collins & Duguid, 1989). It is acknowledged that teachers' prior beliefs and knowledge related to classroom practice influence their interpretation of new pedagogical ideas (Putman & Borko, 1997) and new practices. However, teachers also learn a great deal from their social interaction(s) in discourse communities when they share experiences from the classroom contexts in which they experiment with new or alternative practices (Putman & Borko, 1997). During the teacher development process pertaining to cyberhunts, participants received regular opportunities for reflection through the completion of journal sheets at the beginning and end of the various cyberhunt teacher development sessions. This is in line with Hoban (2002) and Turbill (2002) who state that reflection and communities of practice are two important keys to assist with teacher development.

As a result of the value of social interaction as a learning tool through language, the knowledge creation model of Nonaka and Takeuchi (1995) was seen as a useful model for learning. Nonaka and Takeuchi (1995) identified two kinds of knowledge that play an important role in knowledge creation, namely tacit and explicit knowledge. The four modes of knowledge creation that are represented by Nonaka (1994) and Nonaka and Takeuchi (1995) are the sharing of ideas (socialisation), combining knowledge to test ideas (combination), emergence of new ideas (externalisation) and developing new ideas and learning by doing (internalisation).

In the first phase, the participants explored the Internet in a guided manner by providing them with web addresses type into Internet Explorer's address bar and then to explore these sites. Participants were also introduced to pre-designed cyberhunts in order that they could get a feel of cyberhunts. The Internet search engine, Google, was also introduced as well as Boolean searching. Participants were also introduced to the taxonomy of Bloom.

The second phase consisted of five stages. During the design copy stage, the project leader modelled the cyberhunt design process and the participants followed the instructions, drawing from tacit knowledge (Nonaka, 1995) and by articulating tacit knowledge, the tacit knowledge is converted to explicit knowledge. Being active participants afforded opportunities to learn from the modelling process and to improve self-efficacy through personal mastery, vicarious experience and verbal persuasion (Bandura, 1997). Two tool stages followed which empowered the participants with Word and PowerPoint in order to prepare them for the design of their group cyberhunts. In the design as a group stage, participants could share their tacit knowledge with one another through articulation by means of discussion and peer assistance while they design collaboratively. As a result the tacit knowledge becomes explicit and participants have an opportunity to try to link the new knowledge to their existing knowledge structure.

The presentation stage was the final stage during which participants received an opportunity to showcase their finished cyberhunt products and to obtain feedback from their peers. The assessment phase was the final phase during which participants were formally assessed.

SUMMARY OF THE FINDINGS

The participants highlighted the importance of the role of the facilitator during teacher development projects and placed a high priority on that person’s people skills and competence. Furthermore, it was noted that clear explanations, approachableness and constant feedback were highly valued. This is in line with Havelock and Zlotolow (1995) and George and Camarata (1996) who argue that building relationships and trust, as well as the containment of anxiety, are vital for teacher development.

In addition, participants indicated that they would highly value that the project facilitator visit them at school to assist them with classroom implementation. This was indeed a very positive stance, as teachers are the champions of change and classroom support could probably assist them to experiment with alternative approaches (Fullan & Smith, 1999; Mouza, 2005), for example by using the cyberhunt strategy.

Participants also highlighted the importance of a paper based guide and notes during training as this gave them some form of security. This seems to concur with Leach and Moon (2000) and (Hodgkinson-Williams, 2005) who highlight the importance of clear guidelines for implementation. Participants also said that they had experienced the training as totally different from any other training they had been involved with before. Data analysis suggests that the positive attitude, patience and good listening skills were valued by the teachers. They also highlighted the fact that the atmosphere was relaxed and that this was appreciated, which is in agreement with George and Camarata (1996) who emphasise the importance to contain anxiety when technology is introduced to people.

The teachers also explained that the training was different, because it was ongoing, not like the normal one day sessions. This emphasis of the importance of training that is spread over some time concurs with Royer’s (2002) thoughts. Overall, the majority of the participants stated that the pace of training was important. An aspect that made the use of capable peer facilitators very different and attractive, was the fact that the peer-facilitators could assist their fellow peers in their home language, isiXhosa. This enabled them to often render greater assistance to their peers than could be done in English. Consideration of the language ability of participants during teacher training is thus very important, as this could influence the successfulness of the training. In sum, the following aspects are vital for teacher development, namely (1) establishing a relaxed atmosphere, (2) containing anxiety, (3) the pacing of the training by taking the progress of the participants into consideration, as well as their individual needs, (4) using peer-facilitators, (5) modelling/coaching and mentor when appropriate and when required, (6) Be patient, approachable, and listen to the their learners’ needs, motivate them constantly, assist them and compromise when necessary (people skills), (7) Ensuring that the training is ongoing and progress feedback should be provided on a regular basis, (8) Ensuring that the training is hands-on, practical and explanations are clear, (9) encouraging the use of the participants' home language to explain to one another, (10) providing ongoing support keeping the school context in mind, (11) developing competence, and (12) providing opportunities for personal goal setting, reflection and the sharing of experiences.

The data generated via the teacher development process that was implemented in this study; which is underpinned by the collaborative, motivational, knowledge generative and situated cognition approach corroborated by cognitive apprenticeship principles; suggests that the intervention was effective. These data also informed the design of the framework discussed below for teacher development of this nature.

A PROPOSED FRAMEWORK FOR TEACHER DEVELOPMENT

This data suggest that the following aspects encompassed by the acronym $CRAR^3FS^2$, as indicated in Figure 1, can enhance teacher development and classroom implementation of this type of Internet-based teaching and learning strategy. The $CRAR^3FS^2$ acronym represents the verbs or actions that the participating teachers highly valued during implementation and what they have indicated as being important. The verbs or actions of the $C\ R\ A\ R^3\ F\ S^2$ framework are (1) Care, (2) Relate, (3) Assess, (4) Reflect, (5) Read, (6) Re-Plan (7) Feedback, (8) Share and (9) Support. The diagram also provides an overview of the proposed process for teacher development aimed at empowering them to use cyberhunts as a means to introduce the Internet to teachers. The same elements that were valued by the teacher participants during the teacher development training process should also form part of the implementation process of ICT related learning in their classrooms. Within the $CRAR^3FS^2$ framework, reflection through journal writing or by means of the completion of reflection sheets plays a vital role.

Care refers to establishing a learning context in which learners can experience and see that they are cared for and believe that the will be able to succeed with the new approach. Relate refers to building a relationship between the facilitator and the learners. Assess implies that the teachers should assess and identify the positive and negative aspects that have occurred during implementation.

Reflection refers to the completion of reflective journals consisting of several questions to which participants can reflect upon. The rationale behind the reflective journals is that they are a tool that enables both the designer and the teacher to obtain a snapshot of his/her progress for future planning. Hence, journal writing is strongly advocated as a tool to assist both the teacher and the learners in their planning, to determine their progress and to identify areas in which assistance is required.

Read refers to the teacher who has to read what the learners have written in their journals with a view to identifying aspects that would need attention the next time they continue with their cyberhunts. Re-plan and read is interlinked, as the teacher reads the journals to plan or re-plan for the next session in such a way that he/she addresses the issues at hand. It is also important to note that learners could also read one another's personal reflections in their journals, in order to assist them to understand that they are not the only ones who struggle with certain cyberhunt design aspects. Alternatively, the journals sheets could become an identifier of the 'capable peers' in their class whom they might approach when they need assistance.

Feedback is another important element, as constructive feedback during the lesson, at the end of the lesson, after personal observation, or feedback given after scrutinising the participants' (learners') journals, should assist the teacher to provide adequate feedback and help with preparation and planning for the next session. Share refers to the teacher creating opportunities for the learners to share their experiences of the learning process with their peers either in their groups or with the whole class in order to articulate their tacit knowledge, experiences, successes and needs. Lastly, support refers to both the project facilitator's and participants' role of rendering on-going support when the school based implementation process commences.

Support implies support that is on-going. This implies support from the project facilitator (or from the teacher when the teacher is involved with his/her learners) and from fellow expert participants (the peer-facilitators or from fellow learners within the school context) during classroom implementation. Thus, just as the project facilitator supported the participants during the training process, the participating teacher supports his/her learners in the classroom and the peers support one another too in a similar manner.

Support also implies classroom visits by either the project facilitator and/or other capable peers in order to render assistance and/or to discuss the successes, the areas where assistance is required and to plan how to address the identified issues at hand. The support aspect goes beyond classroom visits, as it also requires the establishment of an internal school based support group which will have to meet regularly to establish caring support. Furthermore, support implies that the principal and the senior management team (SMT) create the necessary learning space for the participants from their school, and support them on emotional, motivational and resource levels.

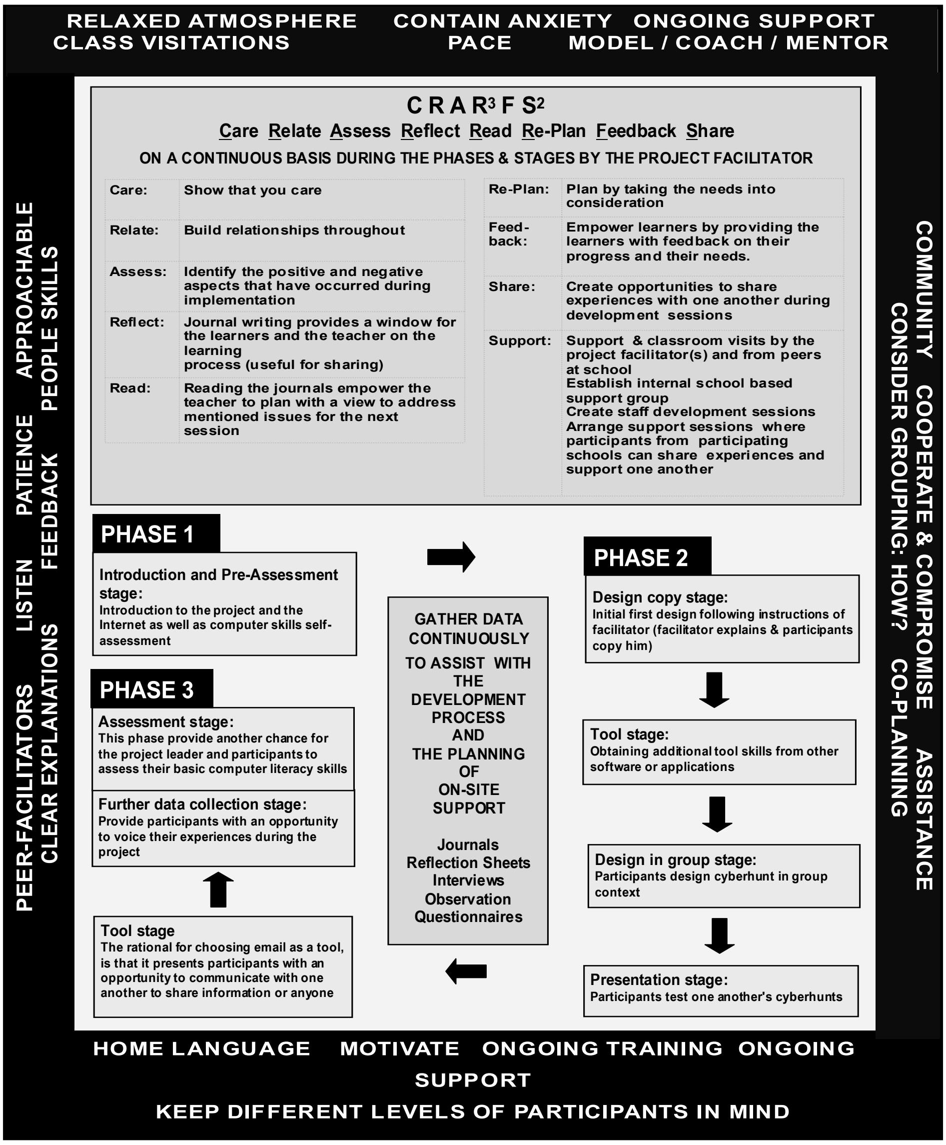


Figure 1: **Proposed phases and stages for teacher training and development related to cyberhunts**

In addition, support requires the institution of staff development sessions in order that the participants, who have received training, can share with other staff members who did not attend the training sessions what they had learned. Equally important, the staff development sessions can then also serve as training sessions for other staff members who want to be trained. Support also implies that the project facilitator and the participants decide upon specific times when all the participants from the different schools can meet in order for the participants to share their school-based experiences with participants from other schools.

The support session for teacher development thus become forums and during these sessions a platform is created to identify the areas in need for further training. These platforms enable the project facilitator to plan for future on-going support training sessions, as the facilitator plans by taking the identified need of the participants into consideration. The project facilitator can then decide whether the future training sessions will be planned by either the project facilitator alone, with the assistance and input of expert participants or by the expert participants on their own. Without the necessary ongoing support, it is highly likely that the implementation process at schools and the staff development at the participating schools could grind to a halt.

It is important that the facilitator (or the teacher who implements the ICT related activity at school) should also take note of the following aspects and responsibilities, during the teacher development process. These aspects and responsibilities forms part of the CRAR^{3}FS^2 framework and have to be planned for and kept in mind for the teacher development process to be successful, namely: (1) Establish a relaxed atmosphere, (2) Contain anxiety, (3) Pace the training by taking the progress of the participants into consideration, as well as their individual needs, (4) Use peer-facilitators, (5) Model/coach and mentor when appropriate and when required, (6) Be patient, approachable, and listen to the their learners' needs, motivate them constantly, assist them and compromise when necessary (people skills), (7) Ensure that the training is on-going and progress feedback should be provided on a regular basis, (8) Ensure that the training is hands-on, practical and explanations are clear, (9) Encourage the use of the participants' home language to explain to one another, (10) Provide on-going support keeping the school context in mind, (11) Develop competence, and (12) Provide opportunities for personal goal setting, reflection and the sharing of experiences. All the elements of the CRAR^{3}FS^2 model should be addressed at any point in time within the teacher development-training process. However, the care, relate and support components should receive attention from the start and should be on-going, as these components contribute to the creation of a positive learning context from the start.

CONCLUSION

The purpose of this paper was to present a framework for teacher preparation and teacher development regarding science education by means of cyberhunts as an Internet strategy for teaching and learning. It is proposed that the CRAR^{3}FS^2 framework for teacher development and classroom implementation can assist teachers embrace ICT implementation and integration. It is hoped that this paper, coupled with further research, might provide a starting point in unravelling a range of complex questions that might assist learners and their teachers to perceive school, especially science education, as being different to what they usually experience. We suggest that in this way ICT implementation in schools could become a tipping point by helping teachers transform their practice through seeing the fruitfulness of the approach and the possibilities that exist. However, the literature and the findings in this study suggest that on-going support is the key in this quest. Although cyberhunts were used as the vehicle for teacher preparation in this case, we do not mean to give the impression that cyberhunts are the only, or the best way, of assisting teachers to embrace ICT implementation and integration. Our experience during this research project does however indicate that the CRAF^{3}FS^2 teacher development framework has been successful to provide teachers with Internet and ICT skills. The framework generated from the data and from the teacher development processes that had been followed, reflects the aspects being viewed as important through the eyes of the participating teachers and teachers should have a voice during the teacher development process.

SOCIAL AND ETHICAL ISSUES IN SCIENCE AT AGE 11 – 14: CREATING COMMUNITIES OF SCIENTIFIC ENQUIRY

Lynda Dunlop	Linda Clarke	Valerie McKelvey-Martin

ABSTRACT

Social and ethical issues in science that raise questions for individuals and society include stem cell research, drug development and exploration of the universe. Forward Thinking, Northern Ireland uses the development of communities of enquiry to promote discussion of these and other social and ethical issues in science with students aged 11 – 14. A questionnaire was used to evaluate this approach in 14 groups of key stage 3 students in 12 post-primary schools involving 301 students. Students reported that they found the project interesting and enjoyable and useful to help them learn science and to think about how they could improve. The majority of students reported that they continued their discussions after class. Teacher participants reported that the project helped them deliver the curriculum and that it supported development of their students' scientific knowledge, thinking skills and social skills. This approach shows potential for extended use in secondary science as a way of engaging students, dealing with social and ethical issues in science, identifying students' misconceptions and also for promoting thinking skills and improving scientific knowledge and understanding.

Keywords: *community of enquiry, philosophy for children, enquiry, discussion, science, ethics*

INTRODUCTION

Teaching about Social and Ethical Issues in Science

Ethical awareness is taking an increasing role in school science education. The Northern Ireland Key Stage 3 curriculum for students aged 11 – 14 (in the first 3 years of post-primary education) has recently been revised and now includes Ethical Awareness as a Key Element (CCEA, 2010). There are other reasons besides the curriculum for dealing with such issues in the science classroom: Reiss (1999, 2008) argues that science takes place in a social context and therefore ethics and science are inevitably connected, and that teaching ethics within science can help sensitize students to ethical issues, make them think of things they had previously been unaware of, help them improve their knowledge of ethics and also their ethical judgement, and that it may also help them become better people. Other advantages of dealing with ethical issues in a science class are that it may help students consolidate their understanding of a scientific topic, to improve their general thinking skills (e.g. by looking for reasons, counterarguments and examples) and that they might enjoy such classes and thereby become more engaged with science. However, teaching about ethics in science remains contested: some have argued that students' ability to philosophize about science (including ethically) will not be achieved to a great extent given the average intellectual ability of a high school student, the skills of the science teacher to teach science ethics and lack of time required to teach about ethical issues related to science (see Davson-Galle, 2008 and Reiss, 1999). The approach discussed in this paper does not involve explicitly teaching *about* ethics, but rather providing a forum in which students can critically evaluate different points of view on a question or issue (which may be social or ethical in nature) and attempt to reach a (provisional) resolution.

The Forward Thinking Project

Forward Thinking Northern Ireland is a teaching project for 11 – 14 year old students and their teachers that aims to encourage young people to engage with thinking about science and its ethical and social implications using the community of enquiry (also known as Philosophy for Children) methodology developed by Matthew Lipman (Lipman, 2003) and advocated in the UK by the Society for Advancing Philosophical Enquiry and Reflection in Education (Sapere). In doing so, it aims to address poor attitudes towards science in the region: attitudes towards science amongst students in Northern Ireland have been identified as poor compared to those in other countries, particularly in terms of their enjoyment of science and confidence in their general learning abilities (Bradshaw et al, 2007). This disengagement has resulted in declining interest in and uptake of STEM (science, technology, engineering and mathematics) subjects (Department of Education and Department for Employment and Learning, 2009). The community of enquiry approach has been successful for promoting learning, reasoning and self-esteem in other subjects (e.g. Trickey and Topping, 2004, Thwaites, 2005, Sprod, 1999). The Forward Thinking project applies this technique to a purely scientific (including socioscientific and ethics of science) context.

A community of enquiry is a group that is focused on solving the same problem or answering a common question through reasoning together collaboratively through dialogue. It involves teaching the process of thinking rather than what to think. The central idea is to provide a group learning environment in which students cooperate to test, share and improve on their thinking together (Splitter and Sharp, 1995). It is achieved by providing stimulus material (e.g. a news article, film clip, radio interview) and asking students to generate and organise questions based on this material. Students then discuss a selected question until it is resolved or until the students identify another question that must be answered. The role of teacher in the Forward Thinking project is to facilitate the discussion between students rather than participate in the enquiry, e.g. to ask procedural questions rather than provide answers for the students. The facilitator provides the space for discussion, focuses the dialogue and encourages deep consideration of the topic by modeling and the use of procedural questions (Gardner, 1996), rather than substantially inputting to the discussion. The facilitator for example may ask for clarification of key concepts, for reasons when stating an opinion, for examples and counterexamples. All participation in the discussion is voluntary. At the end of an enquiry, students then evaluate the process and the content of their discussion and decide where they want to go next. The community of enquiry approach offers students the opportunity to decide what they think is important to discuss based on the stimulus provided by the teacher. This approach gives students the freedom to opportunity to explore their own questions, and therefore direct their own learning.

Communties of Enquiry in Science

The topics included in the Forward Thinking project are designed specifically to provoke questions about controversial issues in science, particularly social and ethical issues. Themes include stem cell research, human and animal cloning, drug use in sport, pharmacogenomics, the search for exo-solar planets and the Big Bang. A typical session begins with an introduction to or refresher of the science involved in the topic under exploration followed by a stimulus which aims to introduce some of the issues associated with the topic, e.g. a short play about EPO use in sport, a music video or a genetic engineering photo album. The students then reflect individually and collectively on the stimulus and generate questions that they would like to explore. Some of the questions selected by students in the Forward Thinking project are shown in Table 1. Whilst the student-centred nature of question generation and selection means that specific content cannot be guaranteed to be covered during a session, the construction of a community of enquiry in science enables students to use their scientific knowledge in discussion and allow teachers to identify misconceptions and missing ideas that need to be taught in due course, as well as to ensure students use scientific vocabulary accurately.

Table 1: Topics and questions explored during the Forward Thinking project

Topic	Questions generated and selected by students aged 11 – 14
Cloning	Could cloning be used to bring back extinct or endangered species, or are they meant to die off? Why is human cloning illegal? Is it right to clone animals when they can't say yes or no? Should we clone? How would cloned embryos be inserted into the woman?
Intensive Farming	Do animals deserve to be treated like this? Why are bananas yellow? Should we mess with the genes of plants? Should animals be killed for us to eat them? Are we being cruel to animals and livestock? Should we let bananas die out?
Search for exo-solar planets	Should we explore other planets? Could humans adapt to an exo-solar planet? Why would we want to search for other life forms and make ourselves inferior or superior? If scientists find life besides Earth, what will happen to religion? How do we know that we are not the 'aliens'? Is it selfish to go to other planets, if we find them?
Stem Cell Research	Should the government fund stem cell research? Is using embryos in stem cell research the same as having an abortion? Should it even be considered as an enhancement when sick people are really in need of it? Is it better to do stem cell research than test on animals?

As the questions show, it is not the case that social and ethical questions are always selected as most interesting for the community to explore. Other types of questions, including technical questions (e.g. on embryo implantation) arise, and these can present opportunities for students to hypothesize and submit their own scientific ideas to scrutiny of the group.

During the enquiry, students are encouraged to address each other, and refer to ideas that other students have introduced to the discussion. This can be managed using different methods of organizing turn-taking. In the example in figure 1, a small cuddly toy version of penicillin is passed between students discussing issues relating to antibiotic resistance.

METHOD

Preparation of stimulus material

This research uses material created exclusively for stimulating enquiries based on social and ethical issues in science. The resources include short stories, role plays, videos, cartoons and interactive presentations. Figure 1 shows the outline of a typical enquiry session, and further resources are available on the website www.ulster.ac.uk/scienceinsociety/forwardthinking. Each resource includes ideas for introducing or revising the relevant science (e.g. modelling genetic engineering using DNA made from sweets or keyword games), a stimulus that highlights a particular issue (e.g. a cartoon or photo involving genetically modified organisms, e.g. the rhesus monkey used as a model for Huntington's Disease), an activity to help students generate and select questions, such as different voting techniques that can be used, and an evaluation activity where students are encouraged to reflect on the enquiry.

Participants

The Forward Thinking project has involved 301 students in 12 post-primary schools across Northern Ireland, of which 37% attend a selective school and 64% a non-selective school. 28% of respondents attend an integrated school. 52% attend a mixed school, 23% girls' school and 25% boys' school. The project was delivered in 6 – 8 hours of normal curriculum time through subjects including Science, Learning for Life and Work.

ANTIBIOTIC RESISTANCE

ANTIBIOTICS ARE USED TO TREAT MANY BACTERIAL infections. However, abuse of these antibiotics has led to several strains of bacteria becoming resistant to antibiotics. This means that the medicines are no longer effective against these bacteria or "superbugs."

OBJECTIVES

To understand how antibiotics are used correctly;

To explore the issues surrounding antibiotic resistance.

STARTER

Antibiotic use quiz (see page 2). To answer yes, students make a Y with their bodies by raising their arms in the air (as in YMCA), to answer no, they make a cross with their arms, and to answer don't know, they shrug their shoulders. Go through correct answers as you play. Recent NHS campaigns include the following advice on antibiotic use: take antibiotics only when prescribed, finish your course of antibiotics, don't take alcohol when using antibiotics and do not use anyone else's antibiotics. The evolution model can be used to help explain the development of antibiotic resistance.

STIMULUS

Split the class into pairs and give each pair the short paragraph on antibiotics with pictures on p2. Ask each pair to rewrite the paragraph, keeping the meaning of the paragraph the same, but without using any of the same words. Select a few pairs to share their "translations" with the class. Discuss similarities, differences and difficulties they had doing the task. Newspaper stories and/or headlines can also be used to stimulate discussion.

GENERATING QUESTIONS

Give students a couple of minutes silent thinking time to create an individual question based on the stimulus. Split class into groups of 3 and ask each 3 to share their questions and to select one they would like to discuss. This should be written on A4 paper. Read the questions and place them around the room. Ask students to vote by standing next to the question they would most like to discuss. Remove the least popular question and ask anyone who is standing there to transfer their vote by moving. Repeat until only 2 questions remain and start with the most popular question.

REFLECTING ON THE ENQUIRY

"Evaluating with emoticons" activity - see page 3.

NEXT STEPS

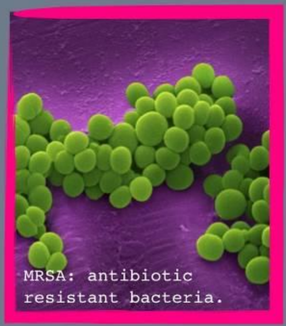
Students could design a survey to investigate understanding of antibiotic resistance and antibiotic use in their school.

Penicillin was the first antibiotic to be mass produced (in 1943). Although it does not kill bacteria, it stops them from reproducing by preventing bacteria from making a cell wall. Cuddly toy penicillin, MRSA and other bacteria are available from www.giantmicrobes.com/uk

Images © Wellcome Trust (www.wellcome.ac.uk) and NHS [1] www.ulster.ac.uk/scienceinsociety/

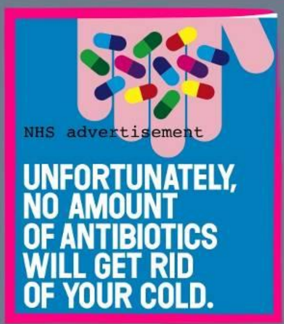
Figure 1(b): Starter and stimulus material for a session on antibiotic resistance

ANTIBIOTIC RESISTANCE



MRSA: antibiotic resistant bacteria.

Penicillium: a common antibiotic.



Antibiotics are medicines used to treat bacterial infections. They don't work viral infections (e.g. most colds and coughs). When antibiotics are used incorrectly, e.g. by not completing the course or by using someone else's antibiotics, it gives bacteria the chance to mutate and become resistant to the antibiotic - this means the antibiotics stop working. Antibiotic resistant bacteria can cause serious illnesses and be spread from person to person.

EVOLUTION MODEL

Bacteria divide many times a day, and some bacterial cells develop a mutation (change to a gene). Some of these mutations may offer resistance to antibiotics. This means that these bacteria are not destroyed by antibiotics: they go on to survive and reproduce. Proportionately more bacteria with the mutation will survive, leading to some strains of bacteria becoming resistant to antibiotics.

Ask for six volunteers to be "reproducing bacteria" and three volunteers to be "antibiotics". The rest of the class observe. The six "reproducing bacteria" will cut "bacteria" from paper using the template below. During a minute of cutting, talk about the bacteria population growing through asexual reproduction, and the limitations of asexual reproduction or cloning for diversity of the bacteria. After 1 minute cutting, introduce mutations, explaining their origin, e.g. from UV radiation, nuclear radiation and chemicals. Model this by giving one "reproducing bacteria" red paper to cut from, asking one to make the shape without scissors and by cutting part of the template. Allow a further minute of reproduction then give the instruction to the antibiotics: destroy any bacteria that are cut from white paper in the shape of the template. Label the remaining bacteria "antibiotic resistant". Discuss what will happen to the population of the different strains of bacteria as reproduction continues.

ANTIBIOTIC USE QUIZ

To answer yes, students make a Y with their bodies by raising their arms in the air, to answer no, they make a cross with their arms, and to answer don't know, they shrug their shoulders. Go through correct answers as you play.

ARE ANTIBIOTICS EFFECTIVE AT TREATING BACTERIAL INFECTIONS? ANS: YES	ARE ANTIBIOTICS EFFECTIVE AT TREATING VIRAL INFECTIONS? ANS: NO	SHOULD YOU STOP TAKING ANTIBIOTICS WHEN YOU FEEL BETTER? ANS: NO - FINISH THE COURSE

Religious Education, Technology and English. 54% of participants were in year 8 (the first year of post-primary education), 22% in year 9 and 24% in year 10.

Data Collection

Work with each group involved between 6 and 8 Forward Thinking sessions. Each session consisted of the following stages: preparation for the enquiry; sharing stimulus material; reflecting on the stimulus, generating questions, sharing and airing questions, voting, enquiry, reflection on the enquiry and last words. The topics were agreed with teachers in advance: some schools requested sessions on a single theme (e.g. astronomy) or topic (e.g. cloning). At the end of the last session, participating students present and their teacher were asked to complete a written evaluation questionnaire.

Studentswere asked to evaluate each session informally (e.g. using interactive handsets or exit tickets asking students to identify knowledge gained and skills used in the session) and to complete an evaluation questionnaire on the final session. Teachers were asked to observe and/or participate in the sessions and to complete a final evaluation questionnaire. A reflective diary was kept by the researcher.

Analysis

Evaluation data was analysed using SPSS. A Mann-Whitney test was used to test for differences between children in selective/non-selective schools and a Kruskall-Wallis used to test for significant differences between young people in girls'/boys'/mixed schools and for those in the first/second/third years of secondary education.

RESULTS

Student evaluations

A total of 260 student evaluations were collected (response rate 86%). Students found the Forward Thinking project interesting (90 % of respondents) and enjoyable (93% of respondents) and have reported that the project was useful to help them learn science (90 % of respondents), think of social and ethical questions related to science (80%) become aware of other people's ideas and opinions (83%) and to think about how they can improve (86% of respondents). Furthermore, children were likely to carry on their discussions about these topics outside the classroom (73% of respondents).

Students in single sex schools were signigicantly more likely to think that the sessions helped them to improve their scientific knowledge (p=0.001; Kruskal-Wallis,□ □ [2] = 13.908), to enjoy the Forward Thinking sessions (p=0.001; Kruskal-Wallis,□ □ [2] = 14.757), to assert that this approach helped them think about how to improve (p=0.000; Kruskal-Wallis,□ □ [2] = 27.229) and made them aware of other points of view (p=0.006; Kruskal-Wallis,□ □ [2] = 10.315) and of different ideas (p=0.000; Kruskal-Wallis,□ □ [2] = 17.722). Students in boys' schools were most likely to say that the sessions made them aware of different ideas and other points of view, followed by those in girls' schools. There were no significant differences in terms of students' likelihood to talk about the topics outside class, or their interest in the Forward Thinking sessions.

Older students (in years 9 and 10) were significantly more likely to say that the sessions helped them think about how to improve (p=0.004; Kruskal-Wallis,□ □ [2] = 11.106) but there were no significant differences in whether they enjoyed the sessions, found them interesting or thought the Forward Thinking sessions helped them to learn science.

Informal evaluation is an integral part of the community of scientific enquiry. For example, on the topic of cloning, students were asked to complete an exit ticket which asked them what knowledge they had gained and what skills they had used during the session. Knowledge gained included that clones are not belly-buttonless (a common misconception in one class), how cloning takes place, that there are several ways to produce clones, the consequences of human cloning, what stem cells are, that a human clone would not be the same age as the parent, that animals have been cloned, that human reproductive cloning is illegal in the UK and about the "good and bad" aspects of cloning. Skills that students identified using included listening, speaking, observing, sharing, thinking, group work, debating, making points clearly, discussing, reasoning, concentration and expressing opinions.

A subset of 18 students at one school were asked to select which part of the session on cloning helped them understand the topic best. They were asked to select from an interactive quiz (using TurningPoint handsets), a jelly model demonstrating cell nuclear transfer, the "Weird Al" Yankovic song and music video for I Think I'm A Clone Now, and the enquiry itself. 17% responded that the quiz had helped most, 11% the jelly model, 11% the song and 61% the enquiry.

Teacher evaluations

Six evaluations were returned from teachers who were present for sessions with their class. (the low response rate reflects the fact that some teachers were not present for more than one session, e.g. in schools were the project was delivered through different curriculum subjects; two teachers who were present for all sessions did not return the questionnaires). All six reported finding this approach useful for delivering the curriculum, for helping their students think about social and ethical issues relating to science and reported that the sessions helped to develop their students' thinking skills, scientific knowledge and social skills, particularly in more reticent pupils. Teachers were provided with access to resources for use in a Community of Enquiry (available on http://www.ulster.ac.uk/scienceinsociety/forwardthinking.html). Six teachers were trained in the use of the technique in November 2009 and others will be invited to attend a training event in 2010.

CONCLUSIONS

This approach shows potential for longer term use in secondary science as a way of engaging students with science and the associated social and ethical issues, identifying misconceptions and for promoting thinking skills as well as scientific knowledge and understanding. Although the limitations are that by handing over the selection of questions to students, it cannot be guaranteed that students will cover a specific part of curriculum content knowledge, there are opportunities to widen learning beyond the curriculum, link meaningfully with other subjects and with everyday life and for students to become more engaged with their own learning.

ACKNOWLEDGEMENTS

This project is funded by a Society Award from The Wellcome Trust. The researchers wish to thank the teachers and students who have participated in the Forward Thinking project

The project is funded by the Swedish Research Council. The research group is called SISC (Science in Social Contexts) consists of Britt Lindahl and Maria Rosberg at Kristianstad University, Margareta Ekborg, Christina Ottander, Eva Silfver and Mikael Winberg at Umeå University, and Malin Ideland, Claes Malmberg and Agneta Rehn at Malmö University (www.sisc.se).

ABSTRACT

We present a research project aiming at investigating how teachers and students in lower secondary school experience work with socio-scientific issues (SSIs). Our interest concerns the importance the actual content has for the students' interest and learning and how students' gender and attitudes towards science, affect their experience. Another interest is how the teachers describe their work with the cases, the students' learning and what difficulties they encounter in the work. We have compared students' and teachers' experiences of the SSI work. Data have been collected by questionnaires with students and teachers and interviews with teachers. The teachers confirm results from this and other studies that students are interested in working with socio-scientific issues. However some of results are contradictory. The teachers felt safe with content and work forms but they still arranged SSI as something special and even if they were comfortable with group work they generally did not seem to know how to facilitate the students' work. Both students and teachers found the work interesting and the teachers but not the students judged that the students learnt as much science as usual. Both students and teachers perceived critical thinking, search for information, and ability in argumentation as learning outcomes that were developed during the work with the case

Keywords: *Socio-scientific issues, secondary school, teachers, students, authentic cases*

INTRODUCTION

In this paper we report the results from a study of how students and teachers experience work with a number of socio-scientific cases constructed for this research project.

There are several arguments for making changes in secondary school science. Firstly, students often express interest in science but they find science in school difficult and without relevance for them (Lindahl, 2003). They are critical about both the content of the school subject and to how it is taught. The students feel that the content is set and that there is nothing to discuss, unlike other school subjects such as history and religious education. During the later years of compulsory school the interest decreases. For a long time this has been most obvious for girls but now it is becoming more common among boys as well

(Lindahl, 2003) At the same time, the students feel that they are not doing well in science - even if they have good marks. This is not the case for other school subjects (Lindahl, 2003; Osborne, Simon, & Collins, 2003). Results from the ROSE project – Relevance of Science Education indicate that there is a gap between what students are interested in learning about and what is taught in school (Oscarsson, Jidesjö, Karlsson & Strömdahl, 2009). It is also most obvious for chemistry and physics. New strategies for increasing young peoples' interest and knowledge in science and their ability to use science outside school are needed (Osborne & Dillon, 2008) to provide students with the knowledge they need for life in a modern society.

Secondly, the Swedish curriculum and syllabuses for science state that students should develop knowledge not only in scientific content but also in knowledge *concerning scientific activity* and knowledge *concerning the use of knowledge* (Skolverket, 2000). However, according to the latest national evaluation (NU03), these last two aspects seem to be taught to a lesser extent in school (Skolverket, 2005). Also, international studies show that many teachers teach the scientific content in preference to the nature of science (Sadler, Amirshokoohi, Kazempour & Allspaw, 2006). Unfortunately NU03 also shows that many students do not reach the goals for conceptual understanding, as described in the national course syllabuses in science for school year nine (Skolverket, 2005). In other words, students in general find science boring and difficult, they are not taught what is stated in the curriculum and they do not reach a satisfactory level in what they actually are taught.

Work with SSIs can be a means of overcoming some problems with school science: to raise interest in science, to cover all aspects of the curriculum, and to involve a more interactive and dialogic pedagogy. Some general characteristics of SSIs are: they are important for society, have a basis in science, involve forming opinions, are frequently media-reported, address local, national and global dimensions with attendant political and societal frameworks, involve values and ethical reasoning, may involve consideration of sustainable development and may require some understanding of probability and risks, and there are no ”right” answers (Ratcliffe & Grace, 2003). To work with SSI means to work with content both *in* science and *about* science, as stated in the Swedish curriculum. SSI are said to be vehicles for strengthening generic skills as team-work, problem-solving and media literacy (Ratcliffe and Grace, 2003). Decision-making and argumentation are also important in work with SSI. Research has revealed that such issues challenge students' rational, social and emotional skills (Sadler, 2004) and other studies show that students are interested in working with issues with a more humanistic perspective (Aikenhead, 2006). However, several problematic factors are identified, such as that the students can easily be distracted when they are working with complex issues where the outcome often is not clear (Zeidler, Sadler & Simmons, 2005). Aikenhead (2006) argues that issues with a humanistic perspective are often complex, and therefore difficult to understand. Sadler, Barab and Scott (2007) state that significant work remains in order to ascertain the link between SSI curricula and the learning of science content.

Research shows that teachers find it difficult to teach SSI as well as argumentation. The problem does not seem to be the content in itself, but rather to teach ideas about science and to conduct teaching which includes decision-making and argumentation (Gray & Bryce, 2006). Newton, Driver and Osborne (1999) report, that teachers often do not have faith in their ability to conduct teaching in which the students engage in argumentation. Teachers also feel insecure in to what extent they should be involved themselves in the classroom discussions and to handle the anxiety or emotions caused by, for example, work with gene technology (Bryce & Gray, 2004). Teachers also experience tension between educational arguments for devoting time to developing students' understanding of scientific processes and the classroom reality (Bartholomew, Osborne & Ratcliffe, 2004). Most teachers have inadequate ideas *about* science and there is a complex relationship between teachers' stated beliefs about science and how they actually present science in their classrooms (Abd-El-Khalic & Lederman, 2000).

Aim

We present a research project aiming at investigating how teachers and students in lower secondary school experience work with socio-scientific issues (SSIs). Our interest concerns the importance the actual content has for the students' interest and learning and how students' gender and attitudes towards science, affect their experience. Another interest is how the teachers describe their work with the cases, the students' learning and what difficulties they encounter in the work. We have compared students' and teachers' experiences of the SSI work.

The aim is operationalized in the following research questions:

- What cases did the teachers select?
- How interesting do boys and girls find the different cases?
- What are the teachers' and the students' opinions about the cases and how do the cases differ concerning how students judge currency, relevance of the task, and how difficult or easy the content and the task is?
- How do teachers describe their work with SSI cases in terms of students' work and learning?
- To what extent do SSIs provide opportunities for learning as perceived by students?
- What similarities and differences are there between teachers and students?

METHODOLOGY

In Ekborg, Ideland, and Malmberg (2009), we describe a conceptual framework consisting of six components chosen to describe the characteristics of SSIs. The components are: starting point; school subject; nature of scientific evidence; social content; use of scientific knowledge and level of conflict. The purpose is to use it as a research tool for the analysis of different dimensions in pupils' work with socio-scientific issues. The intention is to connect outcomes in learning and interest to the different components. We constructed six cases in which these components vary. All cases were current and authentic: that is, we have used real situations and neither rewritten nor adapted the original starting points of the case. In Sweden, school science is defined as the following subjects; biology, chemistry and physics. As issues related to health or the environment are usually of interest to the general public (Ratcliffe & Grace, 2003), the six cases were chosen so that the subject content is a combination of a doorway into an interdisciplinary topic, and traditional school science. The scientific content includes concepts, theories and processes that are found in most science syllabuses all over the world. However, the framework does not contain information about specific science content such as concepts and processes or suggests content *about* science. A teacher's guide was then developed (www.sisc.se)

The Swedish syllabuses are goal-driven and not very detailed, which has the consequence that teachers are free to choose content and teaching methods as long as their students reach the goals (Skolverket, 2000). It also means that it is almost impossible to give detailed instructions to Swedish teachers and expect them to be followed, as teachers are used to organize the work as they find appropriate themselves.

Sample

70 teachers with approximately 1500 students in Sweden volunteered to work with our SSI cases and each teacher chose one case. A questionnaire was used to measure students' attitudes towards and interest in science before starting to work with the case and a second

questionnaire (N=1100) after finishing a case. 55 teachers answered a questionnaire after the work and seven of them were then interviewed.

Questionnaires

This study is part of a larger study and therefore the questionnaires for students as well as for teachers include a rather large number of items. Here we only describe those that are relevant for this paper. The first student questionnaire aimed at describing the pupils' personal characteristics from several aspects. It included questions about gender, learning goals, attitudes toward science in school and society and beliefs about learning. The second student questionnaire, measured the situational characteristics of the SSI work and its perceived cognitive and affective outcomes and it was completed immediately after an SSI activity.

The teachers' questionnaire included questions about background information and there were three open-ended questions about students' reports, assessment and one question in which the respondents were free to write comments. The statements were chosen to get a brief overview of how different teachers organized the work and what their experiences were. The questions were organized in the following groups: Information about the teacher, the class and choice of case, The teachers' opinions about the case, How the classroom work was organized, Opinions about the students when working with the case, Opinions of different aspects of the students' learning, Reporting on what the students based their arguments on, Resources used by the students and The teachers' personal experience.

All questions (except gender) in the student questionnaires and most questions in the teacher questionnaire used Likert scales with five steps where 1 is *disagree* or *not at all* and 5 is *fully agree* or *to a great extent*, depending on the statement. Likert scale are arbitrary in the sense that we do not know the exact amount of interest or agreement but we assume that the respondents interpret the distances between each of the categories as equal sized intervals. One advantage of consider the scale as an interval scale is that it can be used in the most common statistical procedures (Ary, Jacobs and Razavieh, 1996). The data from the questionnaires were exported to an SPSS™ file. Descriptive statistics - frequencies, mean values, median and cross tabs were used. To test the statistical significance chi-square distribution were calculated. We have also done a Kruskal-Wallis test by comparing the answers for attitude, interest and sex as an analysis of significance.

Interviews

Semi-structured interviews were conducted with one teacher at a time. In the interviews the teachers were asked about: choice of case - why and alternatives; work with the case – detailed discussions about planning the work, about reasons for different choices and about outcome; personal reflections about the case - possible development of cases and influence on teaching. All interviews were recorded and transcribed verbatim.

Firstly, we identified some basic information about the teachers. Then the transcripts were read through several times. The analysis was performed in several steps. We started by coding what the teachers said about the case – content, both in and about science, work forms and outcome and what teachers said about science teaching in general. Based on this coding, we described how each one of teachers worked with the case and how they motivated their choices. We then saw some patterns which we further investigated by coding the transcripts according to beliefs about SSI, school science and how students learn.

RESULTS

In almost all classes the teacher chose which case to work with. Only in a few classes the students were involved in choosing case. Most chosen, with more than 350 students, were the cases *Me, my family and global change* and *You are what you eat* followed by *Are mobiles hazardous* with 200 students and *Laser treatment and nearsightedness* with 100 students. Two classes worked with the case *To hear or not to hear* and only one class with *Climate friendly food.*

The majority of students in this study is positive to school and describe themselves as *be doing well at school*. Less than 50 percent of the students describe themselves as interested in science, with boys and girls expressing a similar view. Approximately 20 % find school science difficult and again there is no significant difference between the sexes.

According to the students, all cases except one were interesting (table 1). There was a significant difference between how interesting the students found the different cases. The most interesting case was *Are mobile telephones hazardous.* Both boys and girls found that case interesting. It was followed by *Laser treatment and nearsightedness* and *You are what you eat*. In each of these cases, half of the student group agreed to the statement that the case was interesting and approximately 20 % disagreed. The only case that was not interesting was *To hear or not to hear* where approximately 25 % of the students found it interesting and almost 40 % disagreed. The case *You are what you eat* was more interesting according to the girls. Both Chi-square and the Kruskal-Wallis test show a significant difference between how girls and boys judge that case. The Pearson Chi-Square has a value of 18.123 (at 4 degrees of freedom) and a p-value of 0.001. All other cases were gender neutral.

Table 1. Girls' and boys' judgment of how interesting the cases were. The questionnaire used a Likert scale with five steps between disagree and agree. In this table steps 1+2 and 4+5 are merged together and instead of actual number of students the percentage is reported. The percentages are shown to facilitate comparison, however, the Pearson Chi-Square value is calculated from the frequencies on the five steps in the Likert-scale. The p-value is a measure of the statistical significance.

Case	Sex	N	The case was interesting			Pearson Chi^2 and p-value
			Disagree %	Midway %	Agree %	
You are what you eat	Girls	178	17.4	25.3	57.3	18.123
	Boys	182	28.6	31.9	39.6	0.001
Laser treatment and nearsightedness	Girls	64	17.2	32.8	50.0	0.056
	Boys	53	18.9	32.1	49.1	0.973
To hear or not to hear?	Girls	14	35.7	35.7	28.6	0.221
	Boys	23	39.1	39.1	21.7	0.896
Me, my family and global warning	Girls	202	27.2	29.7	43.1	1.006
	Boys	172	26.2	26.7	47.1	0.909
Are mobiles hazardous?	Girls	106	19.8	21.7	58.5	8.466
	Boys	101	21.8	26.7	51.5	0.076
Climate friendly food	Girls	11	27.3	45.5	27.3	2.369
	Boys	5	0	40.0	60.0	0.306

Both the students and the teachers found the SSIs to be current topics with interesting content and relevant tasks (table 2 and 3). According to the students all but one case had an average value above 3 in the aspect of how interesting the case was, and all had an average value above 3 in the aspects of currency. Furthermore the statistical test, i.e. Pearson Chi-Square values (X) and the p-values (*), show a significant difference between how the different cases were judged by the students (table 2). The cases differ concerning how students judge currency, relevance of the task, and how difficult or easy the content and the task are. The case *Me, my family and global warming* was considered the most up-to-date followed by *Are mobile phones hazardous.* The case *Climate friendly food* and *To hear or not to hear* were not so current according to the students. There was also a significant difference in how easy the students experienced the tasks of the different cases (table 2). The case You are what you eat was considered to be the easiest task and Me, my family and global warning the most difficult task. Overall the students considered the assignments easy to solve with no significant difference between boys and girls in aspects of how easy or current the case was. The teachers considered the content appropriate in relation to the syllabuses, but what is interesting is that they teachers did not, to the same extent, find them appropriate in relation to the students' prior knowledge (mean value 3.1).

Table 2. Students' judgment of the cases; how they value the content and the task in each case. The figures are mean values (average scores) from the 1-5 Likert scale used in the questionnaire where 1 is disagree and 5 is agree. X= the Pearson Chi-Square value and * represents a p-value of $p<0.05$ and ** a p-value of $p<0.01$

Case	N	The case was interes-ting X= 18.59*	Assign-ment related to a current issue X= 63.46**	It was fun to discuss the question X= 32.44*	The assign-ment was easy X= 48.96**	The assign-ment was boring X=22.94
You are what you eat	364	3.32	3.63	3.21	3.43	2.81
Laser treatment and nearsightedness	117	3.40	3.52	3.59	3.21	2.7
To hear or not to hear?	37	2.81	3.33	2.86	3.22	3.51
Me, my family and global warning	379	3.28	4.04	3.27	3.09	2.9
Are mobiles hazardous?	209	3.46	3.71	3.53	3.22	2.78
Climate friendly food	16	3.31	3.24	3.29	3.41	2.75

Table 3. How the teachers value the introduction of the case, the content and the task in each case. The figures are mean values on a scale 1-5 where 5 is agree to the different statements.

Case	Introduction Mean value	Content Mean value	Task Mean value
1. You are what you eat	4.5 (0.6)	4.5 (0.6)	3.8 (0.7)
2. Laser treatment and nearsightedness	3.8 (0.5)	4.3 (0.5)	3.8 (1.3)
3. To hear or not to hear?	4.0 (1.4)	4.0 (1.4)	4.5 (0.7)
4. Me, my family and global warming	3.7 (1.4)	3.7 (0.8)	3.6 (0.9)
5. Are mobile phones hazardous?	2.8 (0.5)	3.8 (0.5)	3.8 (0.5)

The teachers felt confident with the work with the cases. Most common was that the students worked in groups (mean value 4.2). Notable is that lab work was not common when working with the cases (mean value 1.8). Some teachers commented on the lack of lab work, e.g. "It was difficult to find appropriate labs so that it became more theoretical than usual science classes" (teacher number 9). Another reason for not doing lab work was that many teachers worked with the case outside regular science lessons, for example in a special week set aside for thematic work and without access to laboratories. Approximately 40% of the teachers taught part of the topic before introducing the case, which means that they did not use the case to teach new science content. More than half of the teachers chose to present goals from the teacher's guide to the students in the beginning of the work.

Even though SSI cases are about current topics debated and written about in media, the students did not use traditional media for information search to a great extent (mean value 2.6). The most common source was the Internet (mean value 4.1). They also used textbooks (mean value 3.9) and to less extent resources outside school, such as study visits or interviews (mean value 1.3). The teachers' answers also indicate some problems e.g. the students did not easily formulate questions, critically examine arguments or use media for more information about the task. The students did not find it difficult to search for information about the cases. Also, in all cases the students were satisfied with what the different students accomplished during the group work. They found the discussion and each other's standpoints important and perceived that the outcome of working with case had relevance for them. The average score for the girls was somewhat higher on the statement: it was fun to discuss the questions in the assignment. Similar to the teachers' opinion the students also report that the work forms used were quite similar to their regular teaching. The major difference is that in very few classes laboratory work was included when working with SSI.

Learning

We also wanted to know to what extent SSI provide opportunities for learning. Most teachers based their assessment of learning outcome on the presentations, which meant that they assessed oral group discussions and presentations. Few teachers did individual assessment. Even if the work was not assessed individually the teachers found that the students developed critical thinking, learnt to search for information, learnt scientific facts, learnt to apply scientific knowledge, developed understanding of science, and developed ability in argumentation (Table 4). Even if the seven teachers talked differently about teaching and learning, the object for teaching and learning is learning facts. All interviewed teachers, explicitly or implicitly, talked about knowledge as a set of facts which should be taken in by the students.

Table 4. Teachers' responses to statements about students' learning

The students learnt/developed	Mean value
critical thinking	3.7 (1.2)
to search for information	3.6 (1.2)
scientific facts	3.6 (1.3)
to apply scientific knowledge	3.6 (1.3)
ability to argue	3.4 (1.3)
understanding in science	3.5 (1.3)

Almost all students claimed that they learnt new facts during the work (table 5). The case *Laser treatment and nearsightedness* was considered to be the case in which the students developed most new knowledge according to their own judgment. The students reported that they learnt to argue for their standpoint and to search for and scrutinize information. Noteworthy is that the average value of the students self-reported learning outcome is higher for the statement 'learning new facts' than for 'learning science', even though the case was dealt with during science class. Neither did the students claim that they learnt more science than during regular lessons. There was a significant difference between the cases when it comes to how students perceived ‘learning facts’, ‘deal with information’ and ‘argue for an opinion’ but there was no significant difference between the cases when it comes to learning science. The students considered the case *Laser treatment of nearsightedness* as developing most new knowledge, also in science, and also in developing their argumentation skills. It was the case *Are mobiles hazardous?* that developed searching for and scrutinizing information most. The case *To hear or not to hear* were perceived as giving lower learning outcomes on all aspects.

Interpretation of SSI

All the teachers have ideas about connecting school science to reality, but they have not encountered the concept of SSI before. This raises the question of how they interpret the meaning of socio-scientific issues. It was most common that the teacher choose a case that fitted with content that was already planned to be taught. When working with the case the teacher uses the starting point to introduce the content, but does not introduce much new content. It is supported by the result that media and resources outside school are not used to find information. However, they did not automatically fit all the regular school content in these cases, e.g. few included common school labs. The fact that only one of the seven interviewed teachers included lab work can be interpreted as if it is not common to answer questions by doing experiments.

Table 5. Students self-reported learning outcome. The figures are mean values (average scores) from the 1-5 Likert scale used in the questionnaire where 1 is disagree and 5 is agree. X= the Pearson Chi-Square value and * represents a p-value of p<0.05 and ** a p-value of p<0.01

Case	I have learnt new facts X=45.54**	I have learnt to search information X=35.86*	I have learnt to scrutinize information X=32.99*	I have learnt to argue for my opinion X41.14**	I have learnt science X=24.23	I have learnt more than in regular classes X=21.40
You are what you eat	4.0	3.3	3.4	3.7	3.5	2.8
Laser treatment nearsightedness	4.5	3.5	3.5	4.1	3.7	2.7
To hear or not to hear?	4.0	3.0	3.2	3.7	3.3	2.3
Me, my family and global warning	4.0	3.4	3.2	3.7	3.5	2.8
Are mobiles hazardous?	4.2	3.7	3.6	4.0	3.5	2.7

The teachers do not express anything which can be interpreted as evaluating or discussing observations and results. However, there are some indications that the teachers reflect on some of these aspects. One teacher for example, discovers that different websites give different results when calculating amounts of carbon dioxide emissions. When he thinks about it again, he thinks this is a good thing because then he can talk with his students about these differences and why they occur. Another teacher dares to choose *Are mobile telephones hazardous?* and she is well aware of the fact that the information about radiation and health is contradictory. Several teachers talk in general terms about the importance of learning how to use and apply scientific knowledge, but they are vague and they do not give any examples.

CONCLUSIONS AND IMPLICATIONS

This study confirms results from other studies that students are interested in working with socio-scientific issues (Sadler, 2004; Aikenhead, 2006). However the teachers in this study do not seem to be as concerned as the teachers in Bryce and Grays study (2004) about teaching argumentation and decision making. They did not feel the tension between devoting time to developing students' understanding of scientific processes and the classroom reality (Bartholomew et al., 2004). Instead they found the cases interesting and felt safe with work forms such as group work as well as with the content. They answered that the students learnt as much as during ordinary teaching.

The students did not learn as much science as in ordinary lessons according to their own judgement and they found cases interesting, however they did not find them as interesting as the teachers did. Taking into account that the teachers commented in the questionnaires and talked more elaborated in the interviews about problems with the students' questioning and ability to critically examine media it is reasonable to believe that the work has been rather inefficient. Probably the students have not been properly facilitated, which explains the perceived learning by the students. Another reason for that the students do not find the work as interesting as the teachers do might be that almost none of the teachers included lab work. Even if the students did not learn more science than usual they perceived that they learnt some aspects of science e.g. more facts and to argue. This is in line with our interpretation of the teachers' understanding of knowledge. The idea is to deliver a set of facts to be taken in by the students.

Both teachers and students indicated that group work had been common and that there had been lots of discussion. Especially the girls appreciated the discussions. Reflecting these results with the students' perceived learning it is interesting to note that the students indicate that they learnt to argue but they did not learn more science. So what is their idea of what learning science is about? Maybe it takes some time to get discussions, argumentation etc. to work in way that feels rewarding and is understood as learning opportunities by the students. We believe that teachers need to develop strategies for facilitating group discussions.

ABSTRACT

This paper reports results from a virtual community of practice (ComPratica) used as a tool for bridging the research-practice gap in biology education. ComPratica gathers in-service high school teachers, preservice teachers, researchers, and graduate and undergraduate students. It includes forums and chats about matters related to science education, and has as a central activity the construction of collaborative action research, situated in real classroom conditions, involving teachers and researchers in non hierarchical teams. The initial success of the community is indicated by the high degree of participation of its members, the diversity of themes addressed in the forums, and the development of action research projects focused on the high school teachers' classroom, mostly focused on issues raised by the teachers themselves. In this paper, we describe the community of practice, discuss data concerning the members' participation, and offer a thematic analysis of the messages sent in its forums.

Keywords: *Community of practice, Professional development, Research-practice gap, Teacher education.*

THE RESEARCH-PRACTICE GAP: AN EPISTEMOLOGICAL ISSUE

A research-practice gap is generally recognized by educational researchers and teachers (e.g., Kennedy 1997; McIntyre 2005), and it is also a problem in science education (Pekarek, Krockover and Shepardson 1996). Kennedy (1997) discusses four hypotheses proposed to explain the perceived lack of connection between research and practice: (1) research is not sufficiently authoritative and/or persuasive, as a consequence of limits in its non experimental methodology; (2) research needs to be more relevant to teachers' concerns and classroom work; (3) research needs to be more accessible to teachers; and (4) the education system itself is either too stable or too unstable to be able to respond coherently to research findings.

The first hypothesis considers that educational studies have not shown enough quality to provide compelling, unambiguous, or authoritative results to practitioners. Even though it is currently not very relevant to understand the research-practice gap, this was the characteristic approach to this problem since the 1940s until the post-Sputnik era, in the 1960s. The debates were focused on research designs that might be capable of improving the quality of educational studies. Experimental or quasi-experimental approaches were thought to be necessary and, consequently, there was great concern with the isolation and control of variables. Since the mid-1970s, however, it became widely accepted that research is more likely to be relevant to educational initiatives and practices if it is performed in school and classroom settings, not in labs. We still worry, of course, about research design and knowledge reliability, but we ended up accepting that strict control of variables is impossible in most, if not all, classrooms.

The second hypothesis concerns the lack of relevance of research to teaching practice and is usually related to the limited interest of researchers in addressing teachers' questions, or acknowledging the constraints that act upon teachers' pedagogical work. Kennedy (1997, p. 5) mentions a "dilemma of relevance", which prompts us to put into question the very meaning of "relevance". This dilemma calls attention to the differences between the kind of knowledge built by teachers for use in their practices and the kind of knowledge produced by educational research. In view of these differences, it is not likely that educational research offers the recipes for teaching that, sometimes, teachers are expecting.

The meaning of the "relevance" of research to practice should be questioned from the standpoint of both teachers and researchers. The dilemma of relevance can be partly solved by a process of teacher education with regard to the nature of research and research-based knowledge. Moreover, reflective practice is also another avenue for solving the problem of relevance. Researchers, in turn, need to focus on questions resulting from the needs and concerns of teachers and other actors of the school system (Hargreaves 2000).

If research-based findings are to be used by teachers in the construction of, and reflection upon, their practices, they should be presented in an accessible manner. This is the central idea in the third hypothesis discussed by Kennedy. Research-based knowledge should be accessible in two senses; first, it needs to be available for teachers by means of journals aimed at a teachers' audience, internet resources, etc. Second, and more importantly, it is fundamental to present research-based knowledge in an accessible manner, with regard to teachers' understanding. That is, what is at stake is not only physical accessibility, but, most of all, conceptual accessibility. This leads, however, to another dilemma, since we tend to regard an idea as relevant and accessible if it shows a certain degree of agreement with our system of beliefs (or conceptual ecology). Consequently, research-based knowledge that is conceptually accessible to teachers may be research that does not challenge their presuppositions or introduce new possibilities (Kennedy 1997).

Changes in teaching practice will not follow, thus, from the simple act of informing teachers about research results. The dilemmas related to the relevance and accessibility of research can be discussed in terms of the necessity of framing research-based knowledge in an epistemological form that is more accessible to teachers and more in agreement with the reality of their work and knowledge.

These three hypotheses assume that research might influence practice if one could improve the methods, research questions, dissemination, or some other characteristic of academic work. The fourth hypothesis is more pessimistic, suggesting that several features of the educational systems hold back the influence of research over teaching practices. These systems would be either too stable and, thus, incapable of changing, or inherently instable, because of their susceptibility to passing fads. In one way or another, they would be incapable of answering in a coherent manner to educational research. Maybe this hypothesis is warranted, but simply to accept it may incline us to abandon our role of participants in an unceasing debate about the improvement of education. It is better, thus, to avoid taking this hypothesis at face value and go on with our attempts to bridge the research-practice gap.

McIntyre (2005) puts forward a different perspective on the research-practice gap, which can be connected with Kennedy's arguments about relevance and accessibility. From this perspective, the gap is primarily seen as a problem of relating two contrasting kinds of knowledge, which are at the opposite ends of a spectrum of kinds of knowledge related to classroom teaching and learning. Teachers' everyday work demands a kind of pedagogical knowledge that is very different from the knowledge that educational research is well equipped to provide. By 'pedagogical knowledge', we mean the knowledge that directly informs teachers' practice in managing classrooms and mediating students' learning. This is 'knowledge 'how' and is very different from the kind of knowledge to which research typically leads, which is propositional knowledge, i.e., 'knowledge that' (McIntyre 2005). Since research-based propositional knowledge cannot be simply translated into pedagogical knowledge, several steps are needed to bridge the gap between them. These steps from academic knowledge to practice, and from practice to academic knowledge, will become much easier if teachers and researchers are brought together in truly collaborative teams. In this manner, we will be in a better condition to make research-based knowledge accessible to teachers, even in cases in which their beliefs are challenged by findings and ideas about teaching and learning that seem counter-intuitive.

We believe that the research-practice gap should be a major worry for all educational researchers. Accordingly, we have been actively looking for ways of overcoming it in our own work. In this paper, we report results obtained in the construction and investigation of a community of practice (named ComPratica) that aims at bridging the research-practice gap.

COMMUNITIES OF PRACTICE AND THE RESEARCH-PRACTICE GAP

A community of practice (CoP) is defined by Lave and Wenger (1991) as a group of individuals with distinct sets of knowledge, abilities and experiences, who are actively involved in collaborative processes, sharing information, ideas, interests, resources, perspectives, activities, and, above all, practices, in order to build both personal and collective knowledge (see also Wenger 1998). When a CoP is effectively working, it generates and appropriates a shared repertoire of ideas, goals, and memories. It develops resources, such as tools, documents, routines, vocabularies, and symbols, which bring with them, to some extent, the knowledge built up by the community. In other words, a CoP involves praxis: shared ways of doing and approaching those things that are of interest to the people who constitute it. The concept of CoP is derived from a view of learning as a social rather than individual process. From this perspective, in order to learn one needs to participate, actively becoming involved in social processes, resituating (and not only translating or transposing) the meaning of formal descriptions and prescriptions while carrying out a given task.

Sociological and anthropological researches have documented the characteristics of CoPs and how their members work together and build their relationships (Lave & Wenger 1991; Wenger 1998; Brown and Duguid 20000). CoPs have also been the subject of extensive and relevant debate, focusing, for instance, in issues of language and power inside them (Barton & Tusting, 2005), or how CoPs' members can go beyond sense-making, involving a restricted form of reflective learning, towards critical reflective learning (Ng & Tan, 2009). CoPs have been increasingly seen as adequate tools for teachers' professional development. Consequently, a number of relatively recent applications have appeared, such as CoT, a teachers' community which functions as a preparation program for preservice teachers working towards secondary teacher certification (Barab, Barnett and Squire, 2002), the online CoP Tapped In (Schlager, Fusco and Schank, 2002), and Connect-Me, a virtual community of practice for mathematics teachers (Dalgarno and Colgan, 2007). CoPs can potentially catalyze the double movement from academic knowledge to practitioner knowledge, and vice versa, required to diminish the research-practice gap. That's why we engaged in building and investigating a CoP, named ComPratica, as a way of bridging this gap.

ComPratica includes high school in-service biology teachers, preservice biology teachers, science education researchers and graduate students, and undergraduate and graduate biology students. It is a virtual community of practice, implemented in the Virtual Learning Environment Moodle™ (http://moodle.org), a reliable and user-friendly platform, which is implemented in our university, is entirely in Portuguese, including the instruction manuals and tutorials, and does not have system requirements that cannot be matched by the computers and internet connections available to teachers, either in their schools or homes.

The community is focused on biology teaching at the high school level. It is organized around 6 different forums: (1) news forum; (2) forum about evolution teaching; (3) forum about genetics and cell & molecular biology teaching; (4) forum about ecology teaching; (5) forum about botany teaching; (6) forum about general issues related to science teaching. It was planned to foster the construction of short-term action research projects for the teachers to implement in their own classrooms, in collaboration with the researchers. These projects were intended to arise, for the most part, from the teachers' concerns. Face-to-face meetings are occasionally carried out, in order to discuss how the community is functioning, the planning of action research, the analysis of data gathered during the classroom research projects, or to present specific resources to the teachers, such as teaching sequences or materials, either produced by the community itself, or resulting from some meeting, journal or other source.

METHODS

The investigation was qualitative in nature, amounting to a case study about the use of CoPs as tools for teachers' professional development and for diminishing the research-pratice gap. That is, our main research questions are: Is ComPratica functioning as a community of practice, as defined in the literature? If this is the case, is it possible to find clues that it is an effective tool for teachers´ professional development?

ANALYSIS OF THE COMMUNITY'S DYNAMICS

We obtained reports about the date of entrance and the whole set of actions of each participant of the community by means of a tool included in the platform Moodle™ itself. These data were collected at April 10th 2009, i.e., after one and a half year of existence of ComPratica. We could not gather reliable reports for the subsequent months, due to a problem in the storage of the data in the Moodle™ platform. With the available data, however, we were able to produce a consistent picture of the community's dynamics. It was possible to obtain data about the increase in the number of participants throughout the months until February 2010. We also obtained from Moodle™ reports for each of the forums included in ComPratica, in order to examine the distribution of participation and messages among them, also identifying which participants initiated threads of discussion with more than one message in all of the community's forums (with the exception of the news forum). To obtain data about the messages sent in the forums and chats, we retrieved all the messages, building a database with all the written information in the community.

Thematic analysis of the forum messages

We used two main approaches to characterize the messages sent in ComPratica forums, examining them in terms of both their content and the nature of the activities performed by the members. Here, we will only present a thematic analysis of the messages, carried out from February 25th to March 1st 2010. We obtained categories through an inductive process while analyzing these messages. A message could be classified in a single or in several categories.

RESULTS AND DISCUSSION

The dynamics of the community

ComPratica was initiated at November 27th 2007. In February 2010, the community was composed by 87 members. In Figure 1, we can see the dynamics of the community in terms of the number of participants throughout time. The pattern of growth observed in the community after two years of existence is a sign of its health and evolution.

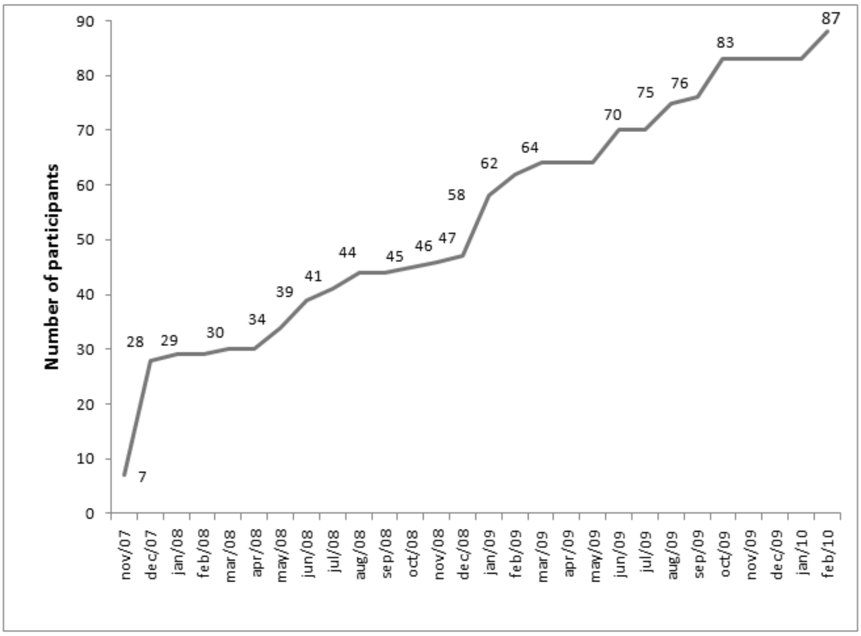

Figure 1: The dynamics of ComPratica in terms of the number of members throughout time (data from Feb 18th 2010).

Among the 87 current members, we find 32 high school in-service biology teachers (four of them also graduate students), 13 preservice biology teachers, 18 university teachers (ten also graduate students), 11 graduate students who are currently not involved in teaching, 9 undergraduate students, and 4 members who are engaged in other activities. The presence of a population with diverse interests and backgrounds is another indicator of the health of a CoP (Schlager et al. 2002) that is fulfilled by ComPratica.

Figure 2 shows the distribution of participation among the members until April 10th 2009, considering how many months have passed since their entrance in the community. We can immediately perceive a huge variation in the degree of participation among the members. Five members (7.8%) show the greatest number of actions in the community, ranging from 998 to 2101 records, including all kinds of action, not only writing messages. Three of them are high school teachers (VAP, ACS, DFA) and one is a preservice teacher (MAL). This suggests that the CoP is stimulating a significant engagement of at least part of the teachers.

While these three in-service teachers are quite active participants, writing many messages both in forums and chats, initiating threads of discussions, proposing topics for the chats, and engaging in the construction of teaching sequences for classroom action research, the pre-service teacher illustrates a silent manner of participation. We do not see her writing many messages or explicitly engaging in many activities. Nevertheless, by checking the records of her participation, we discover that she is constantly accessing the community, reading through most of the sent messages. It is important to notice, however, that the available data highly underestimates this silent participation, since all members receive the forum messages in their personal mailboxes, and, thus, can be participating silently without ever entering the community. In these cases, we can have no record of this participation. We need to use, thus, other means of assessing silent participation in the community.

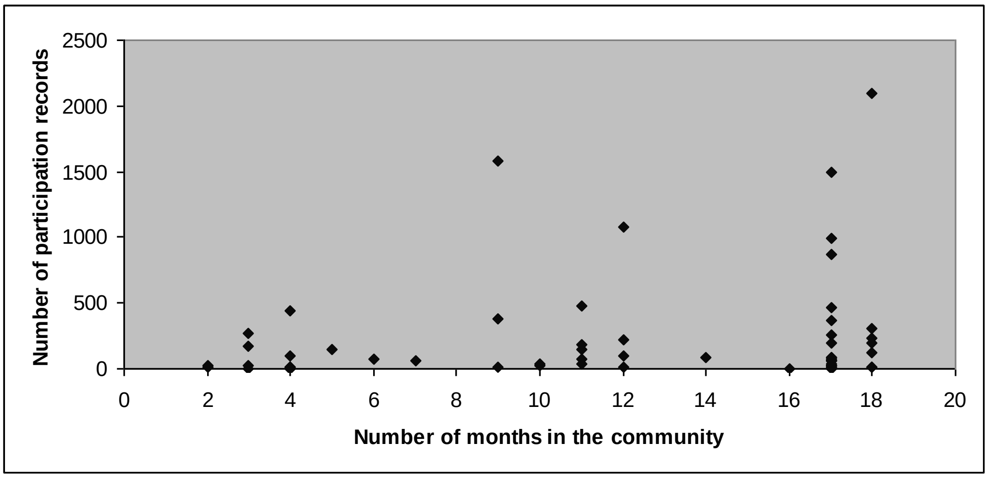

Figure 2: Participation of the members in ComPratica, in relation to the number of months since their entrance. Data from April 10th 2009.

There is a second group of members (20, 31.25%) who are often participating in the community through Moodle™, but does not reach values of recorded actions as high as the most active members (Figure 2). Anyway, this is also a quite significant participation, ranging from 92 to 869 recorded actions. Since many of these participants are in-service and pre-service teachers, their level of engagement provide further support to the conclusion that the community is really contributing to teachers' professional development.

Figure 3 shows the distribution of participation in the community until April 10th 2009 in a manner that considers silent participation with greater precision, since it takes into account the members' involvement with activities playing a central role in ComPratica. In the figure, members are distributed in circles according to their levels of participation, as indicated by recorded actions in Moodle™. Taking only these data into account, we find the five members with the highest degree of participation (7.8%) and 20 members with intermediate levels of engagement (31.2%). If we consider other activities that show an effective engagement of the members, as a way of including silent participation in our appraisal, such as (1) engagement in the construction, implementation, and testing of teaching sequences (MDG, CMU, CS, CF, CP, VRE, LCO, LCC, IS); (2) frequent initiation of threads of discussion (CS, MIB, LCO, LCC, IS); (3) involvement in the maintenance of the community (IG), we reach the figure of 16 members (25%) with a strong engagement in ComPratica. This inclusion appears as arrows in Figure 3, which show participants who move to the center of the community if we analyze other data besides the recorded actions.

If we consider that 25% of the ComPratica members showed, in the data gathered in April 2009, significant levels of participation, with no indication that participation has been diminishing in the last months, we will be able to conclude that the community has been and is very active. Indeed, it shows levels of participation that are much greater than those typically observed in virtual communities, where 90% of the users are generally lurkers, 9% contribute only intermittently, and a small minority (ca. 1%) answer for a disproportionately large amount of content and other activities (Nielsen 2006). Nielsen suggests the following distribution as being more equitable: 80% of lurkers, 16% of members contributing with some material, and 4% answering for most of it. In ComPratica, we observed until April 2009 an even better distribution of participation, with 5 (7.8%) members contribution with a greater amount of material and 20 (31.2%) also giving an important contribution to the community's dynamics (Figures 2 and 3).

We can describe this silent participation observed in ComPratica as a legitimate peripheral participation (Lave and Wenger 1991). This kind of participation is characteristic of communities of practice and plays an important role in professional and personal development. It can be conceived as a process of social learning in which participants gradually engage in exchanges and practices, moving from a more peripheral position to an increasing central place in the community. We observed this movement several times in ComPratica, particularly in the case of teachers who engaged more and more in classroom action research, even though they began (and some of them remained) without writing much in the community.

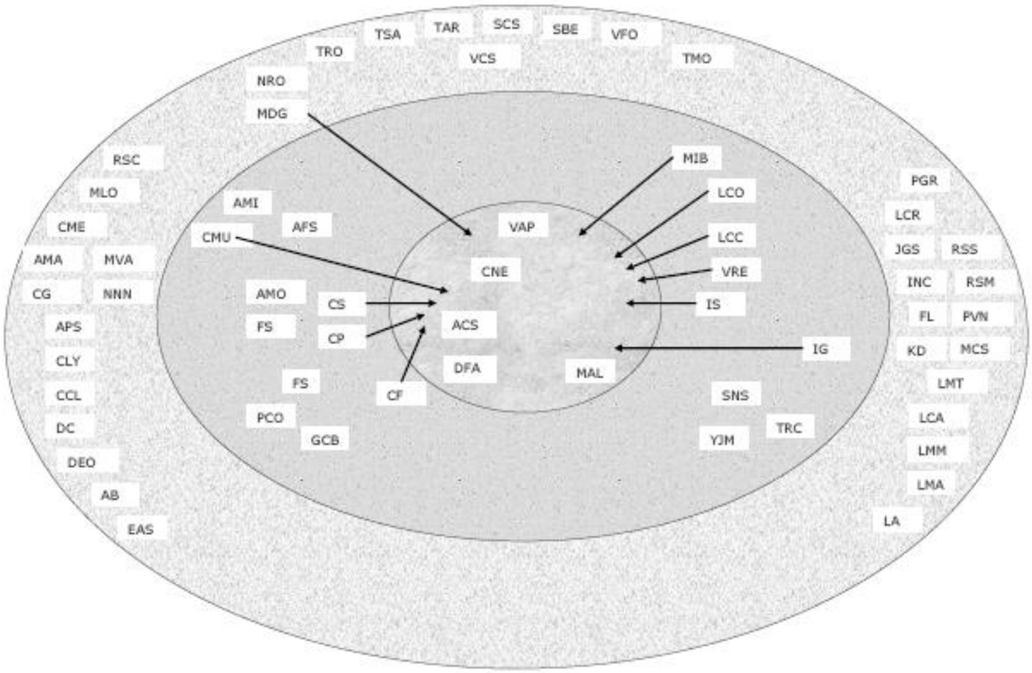

Figure 3: Diagram showing the levels of participation of members in ComPratica. Each member is represented by an acronym containing two or three letters. The outer circle includes members ranging from 5 to 90 recorded actions in the community. The intermediate circle shows members ranging from 91 to 990 actions. In the inner circle, we show members with more than 990 actions. The arrows indicate members with a level of participation which is higher than that indicated by the number of recorded actions in Moodle™. The criteria to identify these members are discussed in the text. Data from April 10th 2009.

All in all, a total of 893 messages had been sent to ComPratica until February 21st 2010 (on average, ca. 32 messages/month). Figure 4 shows the distribution of messages written in the community's forums (with the exception of the news forum) per members. One of the participants wrote much more messages than the other (CNE, 294 messages) due to the fact that he is one of the researchers in the group responsible for running the community and, in particular, for the task of stimulating participation, which is a key element in a CoP (Wenger, 1998). The members who sent more messages after CNE are, however, all high school in-service teachers (ACS, 82 messages; MIB, 70; DFA, 61; VAP, 57; IS, 52). This shows once again that the level of engagement of the teachers in the community is quite significant. A pre-service teacher also sent a considerable number of messages to ComPratica (CP, 24 messages). The same is true of two graduate students affiliated to the research group, who are also university teachers (CS, 42 messages; GCB, 37). Additionally, we should consider that 44 members (50.58%) of the community sent messages to the forums, which is yet another indication of their engagement.

Another data type showing this engagement concerns the initiation of threads of discussion by members of the community, considering only threads that indeed resulted in subsequent discussion (Figure 5). Once again, the fact that CNE initiated 25 threads of discussion follows from the particular role he plays in ComPratica. What is more interesting, thus, is the fact that high school teachers, such as ACS (11 initiations), IS (4), MIB and CMU (3), had provoked discussions throughout the existence of the community. Furthermore, the graduate students/university teachers GCB (6), CS (5) and LCC (3) also played an important role in stimulating discussions. All in all, 18 members (ca. 20% of the community) initiated threads of discussion, including 11 high school teachers, 2 preservice teachers, 4 graduate students (3 also university professors) and 1 university professor. These data add, in sum, to the evidence of substantial engagement of the teachers in the community.

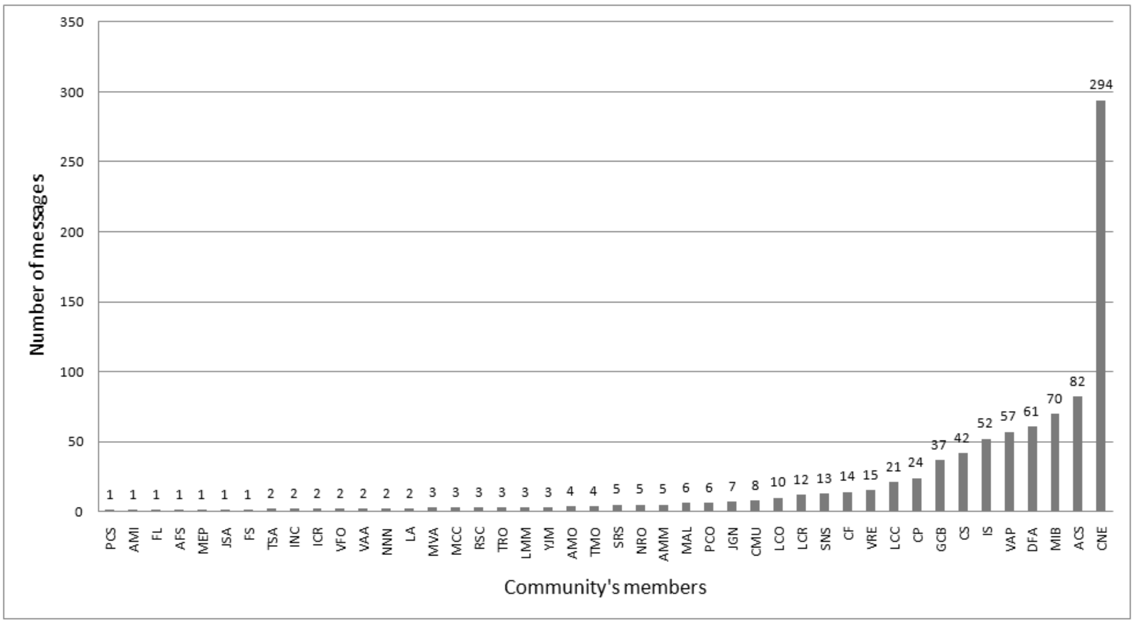

Figure 4: Distribution of messages written by the community's members in ComPratica forums, with the exception of the news forum. Data from February 21st 2010.

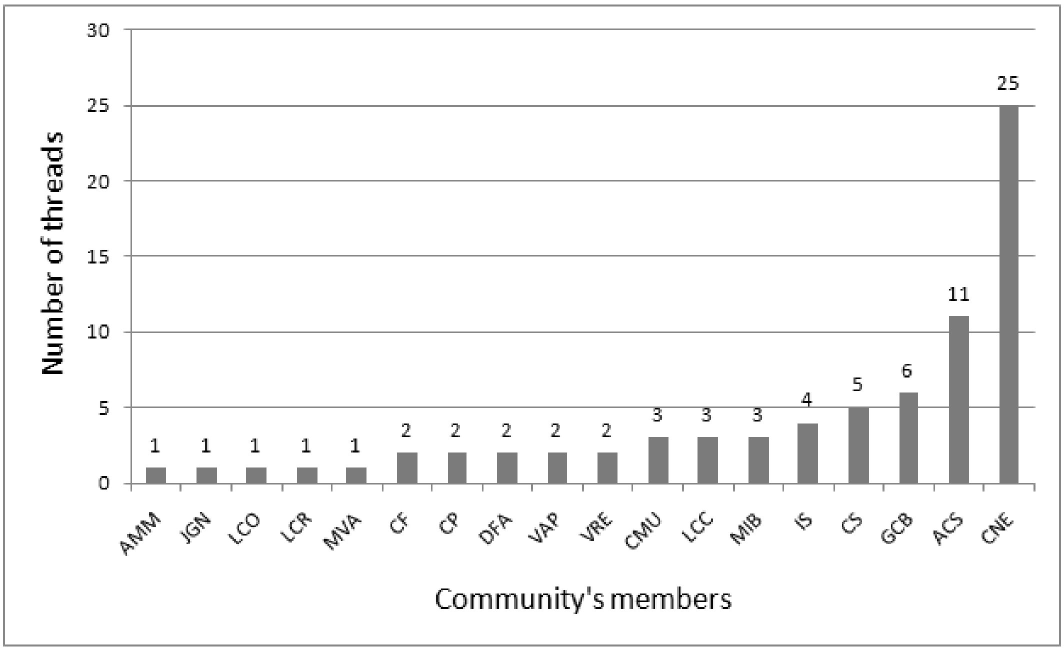

Figure 5: Initiation of threads of discussion by the community's members in ComPratica forums, with the exception of the news forum. Data from February 21st 2010.

Figure 6 shows the distribution of messages per forum in ComPratica. We can see that the forums that attracted most of the attention of the members were those related to general issues about science teaching (497 messages, 54%) and to evolution teaching (251 messages, 27.3%). Significant levels of participation are also seen in the case of the forum on genetics and cell & molecular biology teaching (124 messages/13.5%). The forum on ecology teaching shows a relatively limited number of messages (39, 4.2%). Finally, the forum on botany education has included until now only 9 messages (1%). We consider that there is a lack of interest in this forum, since the small number of messages cannot be merely explained by the fact that it is much more recent than the other forums. After all, in 10 months of existence, less than 1 message/month has been sent to this forum.

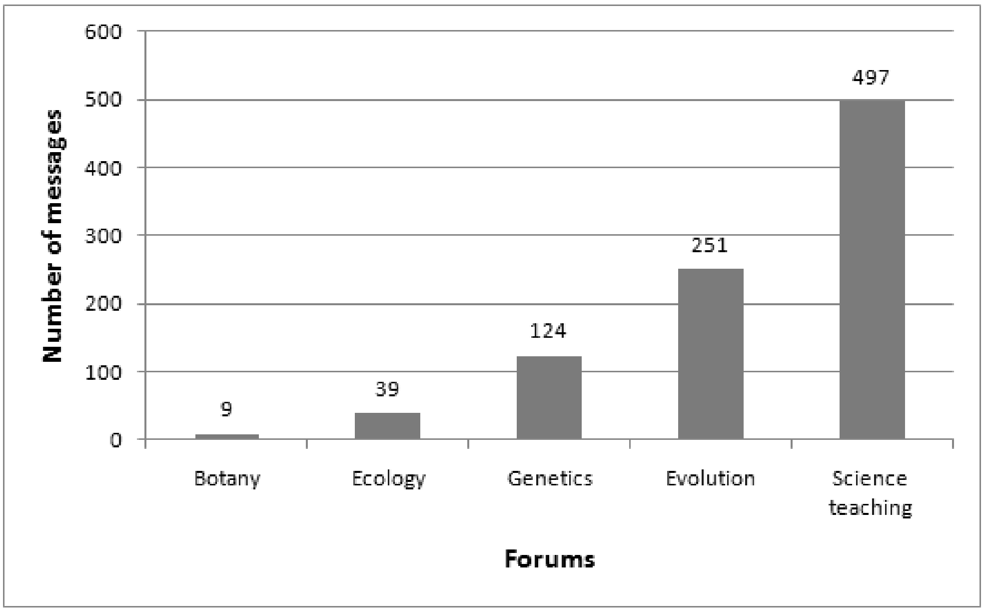

Figure 6: Distribution of messages in the ComPratica forums. Data from February 24th 2010. The total number of messages (920) differs from that shown in Figure 4 due to the interval of three days between the gathering of the data.

Thematic analysis of the forum messages

Figure 9 shows the distribution of messages sent to the forums of ComPratica (with the exception of the news forum). A total of 933 messages were analyzed. The discussion of the teaching sequences developed in the community was responsible for the largest number of messages (247, 26.47%). This is an important finding, since it shows that the community is indeed focused on one of its major goals, the construction of classroom action research about teaching sequences and instructional materials. As planned, action research has been playing a central role in ComPratica, providing us with opportunities of moving along the continuum between practitioner knowledge and academic knowledge portrayed by McIntyre (2005), so as to diminish the research-practice gap. Even though teaching sequences and pedagogical resources constructed outside the community are also discussed, most of the messages were devoted to the discussion of the teaching sequences collaboratively built inside it.

Educational themes were discussed in 178 messages (19.08%), including topics such as the current reform of high school in Brazil, the inclusion of special needs students in the science classroom, problems found in science textbooks, the paucity of the historical treatment of science contents in classrooms and textbooks, and the organization of science curricula.

Many messages (154, 16.51%) were devoted to the dissemination and discussion of texts and media programs, offering a significant contribution to its members' professional development and construction of teaching practices. This contribution also came from messages about internet resources (41, 4.39%), and courses and meetings (14, 1.5%).

The functioning of the community also deserved a lot of attention of its members (153 messages, 16.4%). Many of these messages were related to the organization of activities such as face-to-face meetings and chats. The most interesting of them, however, were those in which members proposed new kinds of activities to be carried out in ComPratica. This was the case, for instance, of a graduate student/university teacher who proposed that the community might have a specific locus for the members to upload texts reporting their classroom experiences or research results.

Among the educational issues discussed in ComPratica, we stressed teacher education and challenges of teaching biology or science, due to their central importance in the proposal of professional development underlying the community. Challenges faced by teachers in basic education were the topic of 115 messages (12.33%), while teacher education was addressed in 80 messages (8.57%). These discussions deserve attention because of the frequent occurrence of reports of the teachers' feelings in the face of the difficulties faced in teaching, which often led to reflections about the quality of their preservice education. This was particularly important to the beginning teachers in transition to practice, who often appealed to the experienced teachers in the community, as well as to the teacher educators, in search of advice about their first experiences as teachers. That's why we regard the discussions about the transition to practice highly important, even though they were the topic of only 31 messages (3.32%).

Conceptual issues were discussed in 97 messages (10.4%), mainly as a consequence of questions posed by the high school teachers. The depth and range of the concepts they wished to discuss were a bit surprising to us. In its two years of functioning, we saw in ComPratica conversations about issues such as the role of evolutionary thought in biology, the nature of learning in the science classroom, the role of tinkering (in opposition to design) in evolution, the relationships between science and religion, and the nature of the scientific methods.

Finally, the research-practice gap and role of communities of practice in bridging it also received some attention in the community (23 messages, 2.47%), in a kind of self-reflective loop.

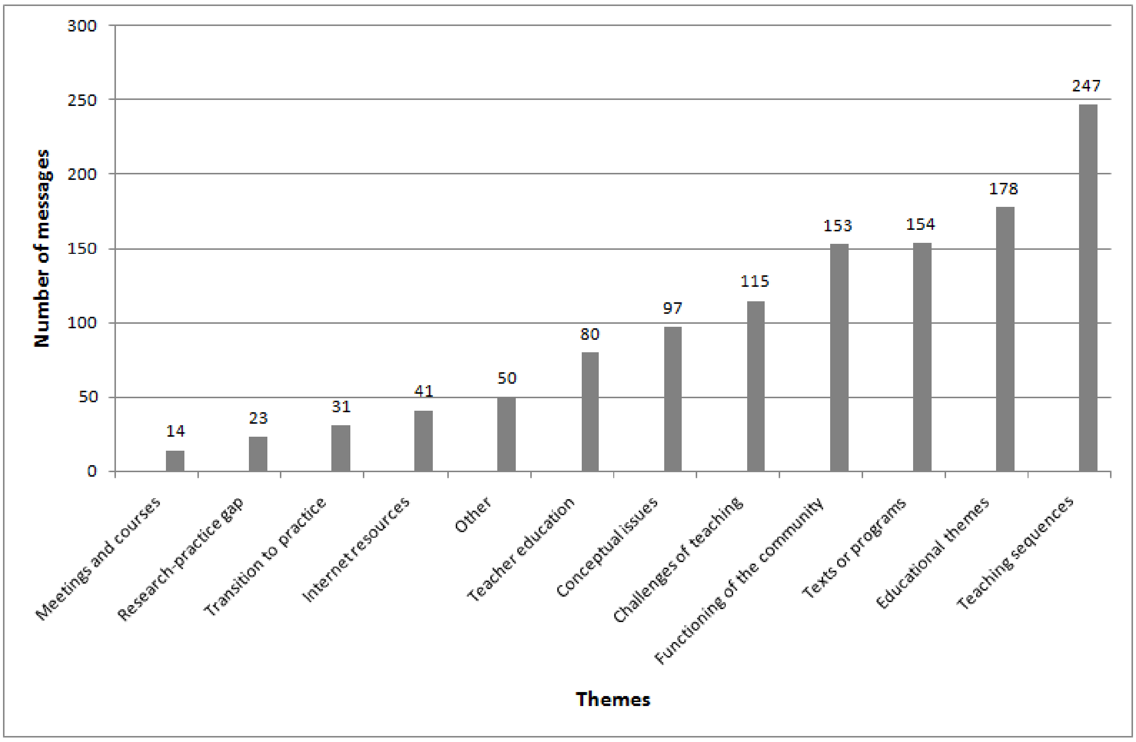

Figure 7: Distribution of messages sent to the ComPratica forums per theme. The categories of themes are explained in the body of the text. Data gathered February 25th to March 1st 2010. The number exceeds that shown in Figures 4 and 6 because this analysis was performed more recently.

CONCLUDING REMARKS

Our goal in investigating ComPratica was to find a way of bridging the research-practice gap. After two years of operation, we can say that this CoP is being effective in making the educational research we carry out much closer to teacher practice. A collaborative atmosphere has been built within it, with high levels of participation and engagement, and the construction of praxis in the form of classroom action research. ComPratica is making room for the integration of a relevant parcel of actors involved in teacher education, educational research, and pedagogical practice, contributing to the improvement of science teaching, the education of future teachers and teachers' professional development, alongside with building a greater proximity between research and practice. The results obtained in the first two years of ComPratica lead us the conclusion that it is growing up to be not only a "community of learners", but, above all, a "community that learns".

BIOLOGY STUDENT TEACHERS AS TARGETS AND AGENTS OF CHANGE

Doris Elster

University Bremen / Institute of Biology Education

Doris.Elster@uni-bremen.de

ABSTRACT

BIOKOMP (Competency-Oriented Teaching and Learning of Biology) is an Austrian project to facilitate the implementation of national educational standards. This requires Austrian schools to transition from the input orientation typical of science education to an outcome orientation. Are teachers prepared for this change? What is the impact of a university education on student teachers' attitudes towards competency-oriented teaching and learning? To investigate these key questions, a questionnaire survey was conducted at the University of Vienna in 2009. A total of 360 biology student teachers (223 beginners, 147 advanced) participated in the survey (quasi-experimental design; factor analysis). Additionally, qualitative data of a new model of school-university cooperation (the BIOKOMP Practical Course; 30 students, 6 teachers; action research) were analyzed. The main findings of the questionnaire survey are as follows: (i) students can be classified as subject-conventional (38%), subject-innovative (11%), method-innovative (26%), or pupil-oriented (25%); (ii) these classifications are based on seven factors that influence attitudes towards fostering competencies; (iii) there is an increase in subject knowledge from beginners to advanced students; (iv) however, only participants of the BIOKOMP Practical Course show a significant increase in epistemological knowledge and skills. To sum up: There is a need for new models of school-university cooperation through which teachers and teachers students work together to promote and foster educational reforms.

Keywords: *pre-service education, competencies, personality traits, national educational standards, educational reform.*

BACKGROUND AND THEORETICAL FRAME

Promotion of competencies in biology education

The disappointing results of the Third International Mathematics and Science Study (TIMSS) and PISA have given rise to a shift in the Austrian educational system, from the input orientation typical of science education to an outcome orientation. Many pupils are unable to apply the knowledge they acquire in school to the solution of complex problems, fail to work on an experimental basis, or fail to argue from the point of view of science (Baumert et al. 2001). These shortcomings of biology education show that the many competencies regarded as vital for participation in modern, knowledge-based society are insufficiently promoted (Bayrhuber et al. 2006).

In Austria the discussion of competencies is connected to the development of National Educational Standards (Lucyskyn 2006). Based on the concept of scientific literacy (KMK 2004), National Education Standards aim to enable students to actively participate in societal communication and to form opinions concerning technological developments and scientific research. A further goal is the development of scientific thinking and working, as well as the critical discussion of the limitations of scientific methods. In summary, the National Educational Standards define four competency areas: subject knowledge, epistemological skills and knowledge, subject-related communication, and decision making and judgment (see Table 1).

Teaching in this standardized framework requires new practices and a re-orientation of instruction from a traditional input orientation to an outcome-oriented approach. As shown by Terhart (2002), increasing attention must be paid to the development of teachers' competencies. Are teachers and student teachers prepared and willing to implement competency-oriented teaching? What is the impact of a university education in this school-based reform process?

Table 1. Competency areas and examples of standards.

Subject knowledge	▪ Understand biological phenomena, concepts, principles, facts. ▪ Convey basic biological facts and concepts, as well as impart complex knowledge, rather than relate details of the subject matter. ▪ Lay the foundation for cumulative learning by connecting biological concepts to concepts in other areas of science, and make these concepts applicable through both horizontal and vertical networking.
Epistemological skills and knowledge	▪ Utilize experiments and other inquiry methods, such as criteria-based monitoring and comparison and models. ▪ Foster an understanding of scientific thought on the working methods applied in biology.
Subject-related communication	▪ Collect and exchange subject-related information and reflect upon norms and values. ▪ Previous knowledge, notions held by pupils, and the learners' level of expertise are of crucial importance.
Decision making and moral judgment	▪ Recognize and assess biological facts on the basis of models of ethical reflection and discern descriptive and normative aspects. ▪ Systematically relate subject knowledge to relevant norms and values so as to arrive at a substantiated conclusion.

Founded by the Austrian Foundation of Research (FWF), the four-year project BIOKOMP (Competency-Oriented Teaching and Learning of Biology) aims to facilitate the development and implementation of standards (Elster 2010) at the levels of pre-service and in-service education.

In the first stage of the project, teachers and student teachers build learning communities (Lave & Wenger 1991; Elster 2009) to plan competency-oriented materials and units. These materials are tested in the classroom. Later, they reflect on classroom experiences and discuss pupils' competencies. In the second stage of the project, competency-diagnostic units are offered via the Internet to establish a blended learning scenario.

On the development of teachers' professionalism in learning communities

The discussion of competency orientation in biology education is strongly connected with a discussion of teachers' professional development. It is assumed that reflection and networking are the keys to promoting change and should underpin school-based reforms (Elster 2009; Elster 2010).

According to theories on teachers' professional biographies (Terhart 2001), occupational development is largely based on a teacher's subjectively experienced and digested teaching practice. Consequently, accumulation of practical knowledge and helpful routines in a teacher's behavior will not be affected by general theoretical insight and developments–i.e., a teacher's behavior runs the risk of remaining subjectively isolated. Hence, there is a need to provide support systems to enable teachers to link subjective experience with theory.

The BIOKOMP project will provide support on a different level. It is assumed that continuing professional development programs are most effective if they include central aspects of professional practice that offer participants the opportunity for "situated learning" (Lave & Wenger 1991). This is ensured by the concept of professional development in learning communities, based on the theory defined by Brown (1997). According to Brown, the experience gained by teachers—in cooperation with student teachers—as a result of their teaching practice can be linked with teaching theories to trigger educational reform processes. Although in the short run this will entail practical modifications of the current teaching practice, in the long run a continuing professional development is anticipated.

Learning communities involving both teachers (student teachers) and researchers of science education provide the settings for the conceptual development of instruction. Teachers implement the plans in the classroom. In subsequent meetings the members of the learning community reflect on the gained experiences in order to facilitate the development of both the concepts and the school's teaching practices. Both the planning processes and reports of results will be accompanied by the teachers' and professionals' reflections to help the teacher develop into a critical and reflecting practitioner (Schön 1987).

It is one of the goals of the BIOKOMP project to integrate biology student teachers into learning communities of teachers and researchers. This is done in the framework of an innovative lecture, the BIOKOMP Practical Course.

The BIOKOMP Practical Course—an innovative model of teacher education

Traditionally, Vienna University's teacher training program is not much different from the curriculum for its biologist training program. Only recently has it become possible to design courses that are specifically addressed to future teachers and that create at least some links between theoretical coursework and teaching practice in a school context. One of the first innovative courses of this kind is the BIOKOMP Practical Course, a new model of university lectures in which student teachers and teachers work in teams to cooperate in the development of competency-oriented teaching materials and units.

BIOKOMP teams one in-career teacher with four to six student teachers. First, they determine the previous knowledge and possible questions of pupils in the second to sixth form (ages 12 to 16) in the school in which they are about to teach. Second, they plan teaching sequences on their topic (e.g., fostering epistemological knowledge and skills using experiments with living animals). On one hand, the teaching sequences offer basic subject knowledge; on the other, they allow pupils to do experiments and to take responsibility for their work as much as possible. For this purpose, the team designs several "stations" at which small groups of pupils can plan, conduct, analyze, and reflect on experiments, assisted by a student teacher.

Another important part of the course is the pupils' reflection on their approaches and on their processes of knowledge acquisition and competency development. The student teachers document their experiences and the findings of the competency diagnostics in a portfolio. These portfolios form the basis of the project reports towards the end of the course.

The teachers of the classes in which the student teachers have their practical experiences introduce the student teachers to the class and show them their facilities and equipment. They do not intervene in the process but rather reflect, together with the student teachers, on the classroom experiences and pupils' competency development.

Is the BIOKOMP Practical Course successful in promoting student teachers' willingness to foster competency-oriented teaching and learning? Are there differences between the participants of the BIOKOMP Practical Course and students who do not participate in the BIOKOMP lectures?

The personality approach in biology teacher typology

Compared to the overall population, biology teachers and student teachers represent a relatively homogenous group. However, differences in professional practices have been identified, especially in regard to readiness to implement new teaching concepts (Neuhaus & Vogt 2005). Whether and in what way personality traits (according to the Five-Factor Model by McCrae & Costa, 1999) have an impact on the attitudes of biology student teachers have not yet been established on an empirical basis.

Against the theoretical background outlined above, this study intends to establish empirically founded types of student teachers (Kluge 1999). This classification will be made in accordance with (i) their personality traits ("Big Five"); (ii) their professional self-concept and attitudes towards teaching and learning (Neuhaus & Vogt 2005); and (iii) their general attitudes towards teaching and the promotion of the following competency areas: subject knowledge, epistemological skills and knowledge, subject-related communication, and decision making and judgment (Elster 2007; Lücken 2006). These characteristics will be related to (iv) the duration of university education (beginners or advanced students) and (v) participation in the BIOKOMP Practical Course.

There are three core research questions:

(1) Do biology student teachers differ from each other in respect to (i) their general attitudes towards teaching and learning, (ii) their attitudes towards fostering competency areas, (iii) their epistemological skills and knowledge, and (iv) their personality traits?
(2) Are there differences between beginners and advanced students?
(3) Are there differences between participants of the BIOKOMP Practical Course and non-participants?

RESEARCH DESIGN

A multifaceted research approach

To investigate the research questions, the author uses questionnaires in a quasi-experimental design (beginner and advanced student teachers) to analyze the student teachers' attitudes towards promoting competency-oriented teaching and learning and to analyze their epistemological knowledge and skills.

Additionally, an action research approach (Altrichter & Posch 1998) is used as a tool for professional development as well as for measuring and analyzing professional development within the BIOKOMP Practical Course.

Action research is expected to support teachers (or student teachers) in establishing a research relationship with their own practice. It should increase their professional knowledge, enhance the effectiveness of teaching and learning, and broaden their autonomous scope. It should empower teachers as "reflective practitioners" to develop their "tacit knowledge" (knowledge in action) through "reflection on action" (Schön 1983). It is assumed that various premises can be made transparent in a value-neutral way by "mirroring" practice. This can facilitate reciprocal learning processes.

Methods, participants, data source

Questionnaire survey. From October 2008 to January 2009, 360 student teachers at the University of Vienna were asked to complete an anonymous questionnaire.

Description of the participants: 81% female, 19% male; 223 beginners, 147 advanced students; age between 19 and 45.

Description of the questionnaire: 126 items in 6 sections:

- *Attitudes towards teaching and learning* (22 items; 4-point Likert scales; based on Neuhaus & Vogt, 2005)
- *Attitudes towards fostering competency orientation* (20 items, 4-point Likert scales; based on Elster 2007; Lücken, 2006)
- *Personality traits* (22 items, 5-point Likert scales; based on McCrae & Costa 1999)
- *Own experiences* with biology as a school subject (27 items, 4-point Likert scales)
- *Epistemological skills:* analysis of two experiments and development of one experiment (open questions)
- *Demographics* (age, gender, years of university education, subsidiary subjects)

The data were analyzed in SPSS using descriptive and factor analysis, as well as means, t-test, ANOVA, factor and regression analyses.

Portfolios. Additionally, in 2008 and 2009, two BIOKOMP practical courses were conducted.

Description of the participants: 30 biology student teachers (90% female, 10% male; all advanced students; age between 22 and 27) and 6 biology teachers (5 female, 1 male; age between 45 and 53).

Data sources: 30 student teacher portfolios with the following contents:

- Description of school and participating teacher (including interview transcript)
- Investigation of pupils' preconceptions, knowledge, and interest (e.g., regarding experimentation with living animals)
- Planning and testing a competency-oriented teaching sequence
- Reflection on class experiences, competency diagnostic, and teamwork

FINDINGS AND ANALYSIS

Based on the data gathered from the questionnaire survey (N = 360), the following results can be reported:

Biology teacher student profiles

Attitudes towards teaching and learning

Regarding student teachers' teaching and learning approaches, four subscales can be identified (explorative factor analysis; four factors [value>1] explain 63.12% of the variance). Based on these subscales, four student teacher profiles can be defined (see Table 2):

subject-conventional profile (38% of the student teachers)

subject-innovative profile (11% of the student teachers)

methods-innovative profile (26% of the student teachers)

pupil-oriented profile (25% of the student teachers)

Table 2. Attitudes towards teaching and learning

Subscales	Number of items	Exemplary item	Realiabilty Cronbach's *α*
Subject-conventional profile	n = 6	The biology teacher should be a subject expert.	α = 0.76
Subject-innovative profile	n = 6	It is important that the biology teacher integrate current research themes into the lessons.	α = 0.86
Methods-innovative profile	n = 5	The biology teacher should be open to innovative methods.	α = 0.72
Pupil-oriented profile	n = 3	The biology teacher should teach themes in a socio-scientific context.	α = 0.61

Attitudes towards fostering competencies

As a result of the factor analysis, the author identified seven subscales (explorative factor analysis; seven factors explain 81% of the variance). The subscales, number of items, and reliabilty are reported in Table 3.

Table 3 Attitudes towards fostering competencies

Subscales	Number of items	Exemplary item	Realiabilty Cronbach's *α*
Subject knowledge	n = 5	In my biology lessons, pupils shall learn domain-specific knowledge (e.g., evolution).	α = 0.77
Theoretical experimental skills	n = 3	I want to instruct my pupils in scientific thinking and scientific methods.	α = 0.73
Practical experimental skills	n = 3	The pupils will learn how to plan, perform, and analyze an experiment.	α = 0.82
Subject-related communication	n = 4	The pupils will be able to interpretate biological diagrams.	α = 0.60
Ethical judgement	n = 3	The pupils will learn to argue scientifically in bioethical discussions.	α = 0.75
System thinking	n = 2	It is necessary to foster interdisciplinary thinking.	α = 0.45
Judgment in the context of sustainability	n = 3	It is important that the pupils learn to accept the environment as something protectable.	α = 0.71

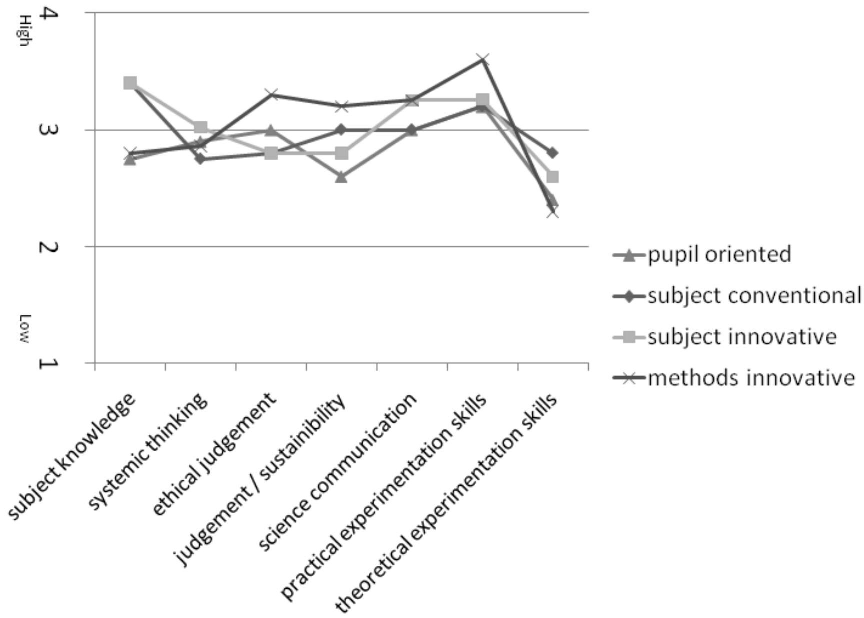

Figure 1. Correlation between student teacher profiles and attitudes towards fostering competencies (N = 360; 4-point Likert scales; 1 = I totally disagree, 4 = I totally agree)

Figure 1 illustrates the correlation between student teacher profiles and attitudes towards fostering competencies. The intention to foster competencies is generally high (4-point Likert scale; means 2.5). Differences exist on the scales of subject knowledge (subject-conventional profile and subject-innovative profile > pupil-oriented profile and methods-innovative profile), ethical judgment, and judgment in the context of sustainability (methods-innovative profile > other profiles). Fostering practical experimental skills is more important than fostering theoretical experimentation skills (e.g., planning or analyzing an experiment).

Correlation between personality traits and gender

In regard to the Five-Factor Model of McCrae & Costa (1999), the five subscales ("openness to innovations," "compatibility and cooperation with others," "conscientisness," "neuroticism," and "extraversion") can be confirmed by factor analysis (five factors [value>1] explain 81% of the variance). Figure 2 shows the distribution of these five factors between male and female students. Significant differences exist only on the scales "neuroticism" (t-test; $p<0.01$) and "conscientiousness" (t-test; $p>0.001$). There is no significant difference between beginners and advanced students or among the four different student teacher profiles.

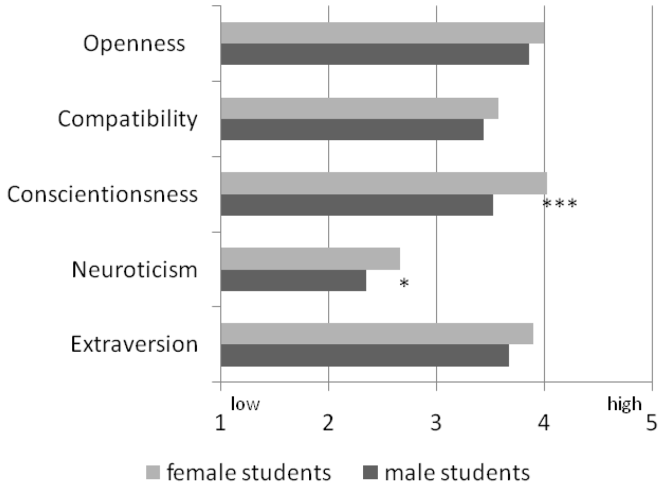

Figure 2: Comparison of personality traits of male (n = 72) and female (n = 288) students. 5-Point Likert Scales. 1 = I totally disagree, 5 = I totally agree. *** $p<0.001$; ** $p<0.01$

Beginners and advanced students

Correlation between epistemological skills of beginners and advanced students

Only 39% of the participating students could identify mistakes in the conduct of experiments. The scores (0-1) of pupils' answers ranged from 0.575 (min) to 0.975 (max). The average score was 0.92. There was no significant difference between beginners (0.90; SD 1.02) and advanced students (0.92; SD 0.82). The author assumed that the student teachers' ability to assess classroom experiments and their epistemological skills could be more developed.

Correlation between beginners' attitudes and advanced students' attitudes towards fostering competencies

It is important for beginners as well as advanced students to foster subject knowledge (see Figure 3). Fostering subject-related communication and ethical judgment is of less importance. In regard to knowledge acquisition, there are differences between "theoretical" (e.g., to think over how to perform criteria-based comparision of plants) and "practical" (e.g., to plan, perform, and analyze an experiment). The results show that there is a significant increase in the attitudes towards fostering theoretical experimental skills ($p>0.01$), systemic thinking ($p>0.001$), and subject knowledge ($p>0.001$) from beginners to advanced students.

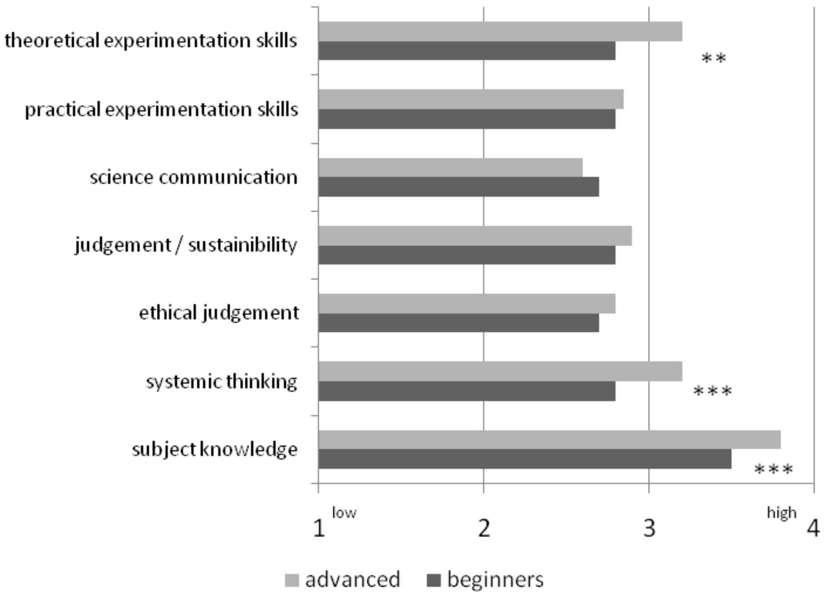

Figure 3. Comparison of attitudes of beginners (n = 223) and advanced students (n=147) regarding fostering competencies. 5-Point Likert Scales. 1 = I totally disagree, 4 = I totally agree. *** p<0.001; **p<0.01

Participants of the BIOKOMP Practical Course compared with non-participants

Based on the analysis of the portfolios of 30 student teachers, the main results can be summarized as follows:

(i) The epistemological knowledge and skills of the participants of the BIOKOMP Practical Course are higher than those of non-participants (participants > non-participants; see Figure 4).
(ii) There is a difference in the attitudes towards fostering subject knowledge (participants < non-participants).
(iii) There is no difference in the attitudes towards fostering ethical judgment or judgment in the context of sustainability.

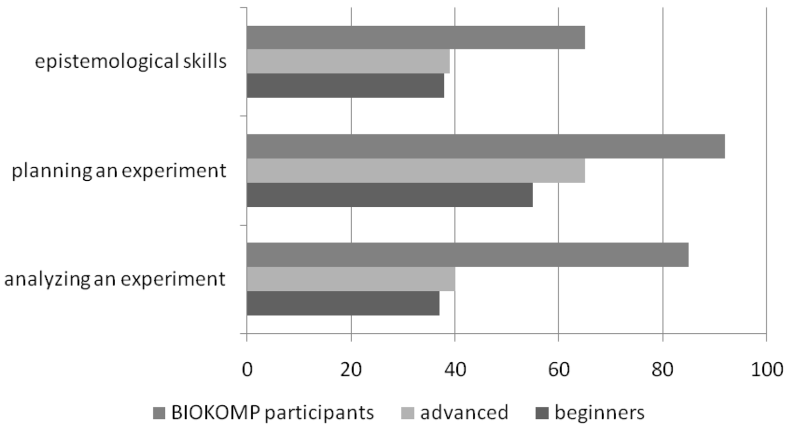

Figure 4. Epistemological knowledge and skills of BIOKOMP participants (n = 30), beginners (n = 223) and advanced students (n = 147). Scores in %.

CONCLUSIONS AND IMPLICATIONS

The initial findings of BIOKOMP allow the classification of students into four profiles. Whereas 49% of the participating students (N = 360) are subject-related (innovative or conventional), 51% are pedagogical-related (method-innovative or pupil-related). These profiles differ in regard to the student teachers' attitudes towards fostering seven competencies: subject knowledge, theoretical experimentation skills, practical experimentation skills, decision making and judgment in a bioethical context and the context of environmental education and sustainability, subject-related communication, and systemic thinking.

There is no correlation between student teacher profiles and personality traits, but there is a correlation between gender and the personality traits neuroticism and conscientiousness (female > male). Extraversion, mental stability, and conscientiousness are accompanied by commitment and openness in promoting competency orientation.

University education has little impact on the attitudes of the student teachers in regard to fostering competencies in the classroom. Significant differences exist only in the willingness to promote subject knowledge, systemic thinking, and theoretical experimentation skills (advanced > beginners); but fostering further competencies based on the standard framework is not reflected or promoted.

The participants of the BIOKOMP Practical Course show a high increase in experimental skills (planning and analyzing experiments) and in epistemological knowledge, whereas the knowledge of non-participants (beginner and advanced) is lower.

In summary, the BIOKOMP Practical Course is an effective tool for fostering competency, diagnostic and epistemological skills, and knowledge. The learning communities of teachers, student teachers, and researchers provide support for student teachers as they reflect on the change from input orientation to outcome orientation in teaching and learning. Student teachers (as well as ongoing teachers and in-career teachers) can be seen as both agents and targets in the implementation of National Educational Standards.

Further research needs to be conducted on how participation in BIOKOMP learning communities influences the concepts of teaching and learning and the professional development of in-career teachers.

ABSTRACT

The declining interest for science and technology among pupils in the Western world is a threat against economical growth, the welfare system and also a democratic problem. A key person for a change is the teacher. We must therefore, as a start, identify what and how teachers in science teach. Results from a survey of physics teacher in Sweden who teach energy in the course Physics A in upper secondary school are presented. Through a questionnaire the teachers were asked what they choose to teach and what methods they use. We found that a majority of them focus on basic physics concepts, their relations and text book problems solving. Overall they teach in a traditional manner, without valuating content and without connecting to the environment, society or future technologies. From a cluster analysis of the answers three different groups of physics teachers were revealed. A large group named the Mainstream Group, a second group, the Future Solution Group, and a third Challenger Group. The latter consist of teachers who, in addition to basic concepts and relationships, also teach with a more valuating content, allowing sustainable development to characterize the content and use a variety of teaching methods and material.

Keywords: *Physics education, physics teacher, energy education.*

INTRODUCTION

Physics education should empower future citizens in a way that enables them to participate and contribute to debate about the role of physics in society and the issues surrounding physics (Cross & Ormiston-Smith, 1996, s. 656).

The Physics subject content in upper secondary school, have an aim for students to achieve understanding of sustainable energy, and consist of basic physics concepts and their relationship. These are exemplified not only in "limited contexts" (a notion that stands for an application, scientific phenomena or an example to which the basic concept can be linked) but also in broader contexts, such as the students own energy use and the energy flows through society and through nature. Within this broader context, it is necessary that problems, such as environmental problems and efficiency problems occur and that a discussion on future solutions is involved. An even distribution should be established between the physical concept, its context and "limited contexts" on one hand and the broader context, related problems and solutions on the other. In addition to the basic physics knowledge, and its connection with the limited contexts, such as certain natural phenomena and technical applications and a basic understanding of the energy flows through the society, students should be able to reflect on the economical and political decisions and values related to energy use (Engström, 2008a; 2008b). The students' own use of energy may be a starting point in that, to let students think about their own situation and compare it with the situation on other continents. The Swedish curriculum for physics (SKOLFS 2000:49) also states the objective that the student should be able to discuss ethical issues related to physics.

An even distribution of the subject content did not appear in physics textbooks or in *one* classroom study when analyzed (Engström, 2008a; 2008b). The results instead show that the emphases are on basic physics concepts, their relationship and large focus on calculation skills. This despite the fact that the curriculum stresses the need for students to obtain knowledge and understanding of energy issues in society and impacts on the environment from the use of energy. Such knowledge is made possible by relating the physics knowledge into context, for the students to 'think in systems', so they understand the processes and problems that the energy use causes, and that the human energy system causes changes in the natural cycles.

The present study is based on the results of an investigation by Engström (2008a, 2008b) on what constitute an appropriate subject content in a physics course in upper secondary school for students to understand and to be involved in society's energy issues, and to realize what sustainable energy stands for. In this article we describe results from a subsequent deeper and broader study of physics teachers - what *subject content* they teach and *how* they teach in terms of energy in the Physics course A (related to a subject content for sustainable energy use) in the Swedish upper secondary schools. Out from this we will present different types of physics teachers.

BACKGROUND

‘SOMETHING MORE’ - WHAT AND HOW IN PHYSICS TEACHING OF ENERGY

Engström (2008a, 2008b) emphasised the importance of reaching an understanding of the problems and solutions, not "only" an understanding of the context. SOU 2004:104 (Swedish official report from the government) mentions that it is not enough for people to obtain knowledge of the cause - effect - conditions that science has highlighted if we want individuals to understand how sustainable development can take place and if we as individuals will realize what we can do to contribute to sustainable development (Öhman, 2003). According to SOU 2004:104 education need to support students to both clarify the causal relationship in a field and point out what individuals can do to influence events in a sustainable direction.

Ideally, the subject content contributes to the students’ ability to realize the strategies that must be asserted in the future, for example requirements on future technologies and what wise choices that are important to make in a person’s lifestyle. Such subject content can be compared to Roberts (1982) "science, technology and decisions - emphases." It is important that students want to work for sustainable development locally and globally (Gayford, 1991; SOU 2004:104). It requires teaching strategies for a holistic approach, a Vision II (Roberts, 2007) where students receive science knowledge for citizenship.

The current Swedish curriculum (Lpf94) value-system, including physics teaching, emphasises a democracy perspective. Teaching should for example enable students to examine their own energy use in discussions, in calculations and in concrete issues. This has two purposes, first the personal experience provides a better understanding and second the students themselves will develop a commitment (Space, 2007), that they need to change attitude and behaviour (Gayford, 1991), that they receive an “action competence” (Öhman, 2003).

To receive “action competence” students have to be trained in detecting and solving problems, and trained to develop critical thinking and they must also gain insight into the natural cycles in order to understand what is happening in different systems (Hansson, 2000). Teaching may also very well contain investigative contexts in which students learn content and recognizing situations in which the content has a value (Barab & Luheman, 2003). Students may get a line of argument, so they can relate physics concepts to contexts, and that they within these arguments realizes that one can and must evaluate different aspects (Space, 2007). The *Reality-based* learning that education for sustainable development requires is very important but contacts with the local community are few and sparse in the school (Öhman, 2003). The student must get a chance to lives through *democracy* in education. To create knowledge means that one, according to Öhman (2003), builds a relation with the world. According to UN (2003) participatory and a holistic approach should imprint the education, students should be encouraged to critical thinking and reflection, education must be process-oriented and participant regimented.

DILEMMAS AND PROBLEMS FOR ’SOMETHING MORE’ IN PHYSICS TEACHINGS

A *dilemma* is that the physics subject has to make students transfer knowledge to another context and “something more”, while at the same time becoming one with the physics culture. To become involved in a knowledge culture is to think, act, talk in a certain way - to master the natural sciences. This culture of natural science is guided by its tradition and its approach (Schoultz et al., 2003; Andersson, 2003; Ingelstam, 2004) for example the importance of understanding a notion in a scientific way. But, as Andersson et al. (2003) argues, scientifically not acceptable perceptions can be part of a set of values which are important for an individual person and the individual's involvement and critical thinking and the school should promote a development in society (which requires that students receive a certain insight) which must give students the right to think freely and express their opinions (Öhman, 2003). A *problem*, exposed with experiences from the PLONE – project (with the intention of democracy in education by including students’ influence), is that it will became difficult for many science teachers accepting that their situation changed to a smaller proportion of lectures in whole class, and more to be a listening party who provides adequate feedback on students' own statements and briefings (Kortland, 2002).

A TRADITIONAL WAY OF TEACHING PHYSICS

The teacher studied in Engström (2008a, 2008b) has a major focus on helping students to succeed in calculations. The teaching is based on the physics textbook and the teacher has selected the appropriate section and allows students to do most of the calculations. Communication in the classroom consists mostly of one-way, the teacher is lecturing and the students are listening and taking notes. This method of teaching is reflecting a attitude consistent with several studies (Thomas, 1990; Tobias, 1990; Staberg, 1994; Benckert &

Staberg, 2001) giving that the subject of physics is a culture not easy to enter and not welcoming, especially for women and to alter traditional teaching is not easy but also not always welcome even among the students. The subject is regarded by the pupils as describing, not reflecting, and answering question never posed by them. Science is becoming a fossil for them (Sjøberg, 2005).

Physics is traditionally seen to be highly mathematical. “Physics teachers have a tacit understanding, strongly shared by the students, that the important aspects of physics have to do with manipulations of mathematical symbols” (de Souza & Elia, 1998, p. 3). In physics as academic subject a common approach is to preserve the contents, with a focus on traditional physics concepts, its scientifically correct definitions in order to understand the context (facts) and to perform calculations (Ingelstam, 2004; Gyberg, 2003)

PHYSICS TEACHERS VIEW AND CONSEQUENCES FOR SCHOOL PHYSICS

Physics teachers in secondary school have a more traditional view of science than elementary teachers. They mean for example that “the only valid way of gaining scientific knowledge was through the application of inductive methods based upon observation and controlled experimentations” (Pomeroy, 1993, p. 262). Teachers in secondary school have a more formal science training which can explain their “deep initiation into the norms of the scientific community” (Pomeroy, p. 269). Why secondary teacher have these values and beliefs can also depend on influences by years of exposures to the presentations of science by text books, an idealised model of science, or working for a long period in schools that value factual knowledge, schools “that often encourage control over creativity and reward teaching students fact auspices of educating them” (Brickhouse, 1989, p. 448).

Physics teachers’ practice teaching within the boundaries defined by very powerful socializing forces and due to Cross & Ormiston-Smith (1996) this has considerable consequences for teaching activities which do not overtly support these values. Some of the standard outcomes of the processes of socialisation of physics teachers are, very shortly: that physics deals with objective knowledge gained through formalized scientific methods, that physics is a difficult subject, that the content of physics is free from the influences of culture and gender, that the achievements of physics can be seen as an ever increasing understanding of nature and therefore power over nature, that the history of physics can be understood by projecting our present knowledge and understanding back in time, that in the minds of teachers the knowledge produced by physicists is placed at a higher order than other forms of knowledge, schooling of physics is likely to be the same wherever physics is taught depending on progress towards increased knowledge requires a systematic approach to knowledge acquisition – progress in physics requires progression via a universally syllabus (Cross & Ormiston-Smith, 1996).

Hansson (2000) argues that the traditional subject division in school makes issues relate to a subject to be locked into specific situations and approaches. The truth is written in the book, in the subject, and expressed by the physics teacher, a person who is perceived as clever because he demonstrates mastery of a subject that is difficult to tradition, a view which, among other, Berner (2004) highlights. It is likely that the scientific culture of objectivity is reflected in textbooks and in teaching. It can be a resistance to evaluate and emotionally take a position on various issues. Gyberg (2003) shows how physics do not involve environmental issues in the same way as for example, the biology subject. Gyberg also describes how energy education in physics is marked of the tradition of facts in physics and do not give the contents related to valued issues the same status.

RESEARCH QUESTIONS

The whole study aim to examine, *based on given frames, steering documents, subject content from Engström (2008a, 2008b), how and what physics teachers in Sweden teach*. We also ask *Are there any challengers*?

METHODS

The Selection Process

To reach all the physics teachers who teach Physics A we contacted all, 1025 secondary schools in Sweden, by e-mail. We informed about the study and asked questions designed to find schools giving the course during the academic year (2008-2009) and asked for physics teachers e-mail addresses. To schools that failed to respond after two weeks we sent a new e-mail with the same questions. Of the 1025 schools we have not received responses from 45 schools. The current e-mail list of 976 physics teachers (Physics A) was reduced (when the survey was closed) of the following reasons: that e-mail address ceased to exist; the teacher is on leave, sick, maternity or other reasons. The range covered by the survey, the respondent list amounts to 913 physics teachers (their e-mail addresses), but the selection may include the addresses of the persons employed by such schools or in municipals but do not teach Physics A, persons who don´t answer the questionnaire. As a web-based survey tool Netigate were used (http://www.netigate.co.uk/) and the teacher answered the questionnaire anonymously.

The preparation of the questionnaire

The questionnaire consists of seven parts and the questions are a mixture of open questions that require written answers and claims to be answered with either yes / no or choice of options. Alternatives are made of actual responses/opinions or claims such as in high grade / low grade, never / seldom / often, etc. The questionnaire includes questions and statements dealing with both *what* and *how* – questions (part 1 in the questionnaire) and questions giving empirical data for the analysis of *why the teachers do as they do* (part 2 – 7 in the questionnaire). Part 1 contains questions about the energy teaching practice in the course Physics A. In total the section includes 86 issues, claims, etc. in which the respondent is asked to take a stand. These questions have a background in and has been reworded based on the study on the topic content for teaching about sustainable energy in Physics A course (Engström, 2008a; 2008b). The questions aim to describe what is taught in terms of energy in Physics A and how teaching is carried out. Part 2 – 7 in the questionnaire are based on surveys made by Pierre Bourdieu (1984, s.512) and other researchers, all using the concept of capital etc. (Broady, 1998) for the analyses. The questionnaire was tested by four physics teacher (one woman, three men) who recently taught the course Physics A. Adjustments were made of certain issues out from their comments.

Tools for result generating and cluster analysis

From Netigate a report is obtained and a data sheet for statistic analyses program “SPSS” (http://www.spss.com). In the report all the variables are summarized in the response rates, presented in bar charts and in free text answers. The free text answers were coded for new variables presented in order to complete SPSS data sheet. The results from the Netigate – report, in which all variables are presented with response rates (also in SPSS data sheet, from which we get frequency tables), presents statements about what and how the physics teachers teach.

We also sought for groups or cluster of teachers using those variables that comprise the choice of teaching with a more valuating content (level D, E and F from table 1). This was done through a cluster analysis by SPSS where we looked for groups of teachers selecting the same subject content. In the cluster analysis we “cluster together variables that look as though they explain the same variance” (Field, 2000). We can explain a cluster analysis as a “way of grouping cases of data based on the similarity of responses to several variables” (Field, 2000). In this special case we made a hierarchical cluster analysis choosing Ward`s method (Squared Euclidean distance, Z-scored for variables, dendogram for presentation).

RESULTS

The response rate

When the survey was closed after six weeks the response rate had reached 29%. This was with three reminders and a personal letter accompanying the final reminder. The survey was answered by 268 persons and was opened and attended by another 222 people and was not opened by 423 persons. The empiric underlying the analysis and the result obtained in this study describes the circumstances of the particular group of 268 teachers. We cannot draw any conclusions as to whether the results are generalisable since there is no access to comparative national statistic for the agreed response rates over different variables such as gender, age, hometown size, education, and years of teaching and current home district. In general, the response rate among the 268 persons for each statement/question came to between 88 and 97 %.

WHAT DO TEACHERS TEACH IN PHYSICS A?

Figure 1 shows the percent of the respondents, and to what extent they respond strongly agree on the respective claim, to each level from table 1.

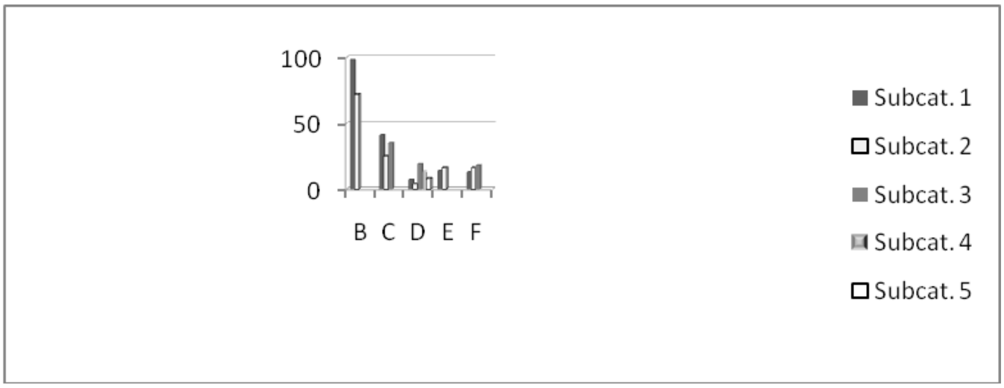

Figure 1. Percent responding, (responding strongly agree about teaching that content), per level in the structure of content.

Table 1. Levels from Engström (2008a, 2008b), a structure of content in energy education in physics.

F-level	More valuating content. Strategies and solutions for the future. 3 subcategories.
E-level	More valuating content. Problems. 2 subcategories.
D-level	More valuating content. Larger context driven by human activities and needs. 5 sub.
C-level	More fact in content. Basic science and technology, ”limited context”. 3 subcategories
B-level	More fact in content. Basic, traditional physics. 2 subcategories (sub. 1: basic energy concepts)

All teachers are teaching basic physics concepts but in summary, approximately 30% of the teachers *teach no* efficiency and environmental problems and strategies for sustainable energy, level E and F respectively. An exception is that 20% do not teach about future technologies. Significantly, almost 20% *refrain from* energy conversion phenomena such as heat engines and almost 70% *refrain* from energy conversions of for example biomass. Furthermore, interpreted the subject content related to environment, politics and ethics are missing. 79% of the teachers focus on the content with the aim that students will learn to calculate with the basic physics concepts and their relationships. Only 13% lets sustainable development guides the content of the energy component of Physics A.

How do teachers teach energy in Physics A?

The teachers say that it is important to build upon the curriculum and implementing it in teaching (72%). The course starts with the teacher having lectures, and then students may calculate and experiment in groups (69%, not true for 5%). Approximately half of all teachers *do not* let the students do work thematically. 22% give students the opportunity to in various ways put their knowledge of physics concepts in a wider context, for example, to link the phenomenon of global warming to climate change. Only 11% let the students work in groups with the course content that they adapt to current events in society and the media. 43% of the teachers let students' have their own discussions, both in group and when they have dialogue in the classroom. 23% give the students space to discuss and evaluate society's energy issues. About 16% of the teachers let the students be involved by determining the content and as many let the students work in teams with specific projects that can be related to concepts, etc. in the curriculum and want them thus to understand the concepts and contexts.

ARE THERE ANY CHALLENGERS?

The cluster analysis is based on *what* the teachers teach and resulted in 8 different teacher clusters. In the analysis we took as input what the teachers answered about teaching a more valuating content (level D, E and F, table 1). The mean value of each category for each cluster has then been calculated, out from the response from every person in the cluster. All questions for the categories have been used in this calculation to find what can be called a center of gravity in opinion. For each cluster we thus have three values, coordinates, to position the cluster in a coordinate system. If all clusters positions are plotted in a 3d-system with the D, E and F categories as axis they will roughly fall on a diagonal axis. In figure 2 we have projected this plot in two planes: D-F and E-F respectively. The figure shows that there are differences, for example that cluster 8 and 2 are with their positions polarized from cluster 3, 6 and 1. Cluster 4, 7 and 5 can be seen as describing something in between.

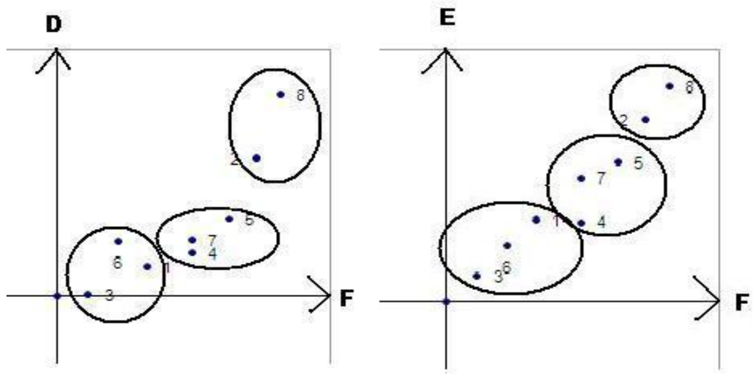

Figure 2. The positions of the 8 clusters in a system where the axis responding to content from levels D and E respective F. It shows the clusters distribution between themselves. For example cluster 8 teachers have a large amount of content from all D, E and F-levels. Cluster 3 teachers have nearly nothing of content D, E and F in their teaching. The elipses give how we out from the cluster analysis and response to the "how" questions, have presented the teachers in three groups.

After we found these clusters we put them in relation to *how* the teachers teach. With cross tables we found characteristic features. By doing a cluster analysis based on what the teacher teach and then finding common features for both what and how we have landed in *three* different groups. Generally we can see main differences between the groups concerning statements with numbers 20 - 34, expressed in table 2. The most distinctive results are visualized in bar charts, figure 3, 4 and 5.

Table 2. Statements from questionnaire. Numbers related to figure 3, 4 and 5. H=How, W=What

34	H	I let the students be involved and determine the content in energy in Physics A.
33	H	I let the students work in teams with specific projects that can be related to concepts, etc. in the curriculum, I want them thus to learn to understand the concepts and contexts.
32	W, H	I let the students work in groups with the course content that I adapt to the current events in society and the media.
31	W	I let the notion of sustainable development guide the content of the energy component in Physics A-course.
30	H	I work thematically in the energy part of the Physics A-course.
29	W	Students will determine themes or projects to work with.
28	W	I let the students have space to discuss and evaluate society's energy issues in Physics A.
27	W	My teaching is not directly related to the book. It is based on any current events in society, TV, article etc.
26	W	My way of teaching is based on students' own discussions, both in group and when we have dialogue in the classroom.
25	W	I do my own calculations examples adjusted to what I am talking about and what the students want to discuss.
24	W	I give room for and take a starting point in the students' experience in energy issues in society.
23	W	I read my remarks on the curriculum (physics), governing document on sustainable development, etc. and translate them into practical teaching.
22	W	I believe that students in Physics A, first of all should be developed for citizens to have a good understanding of energy issues.
21	H	I often use other teaching materials in addition to physics A-book in my teaching about energy in Physics A.
20	H	My way of teaching is based on letting students work more in groups, with both theory and in laboratory work.

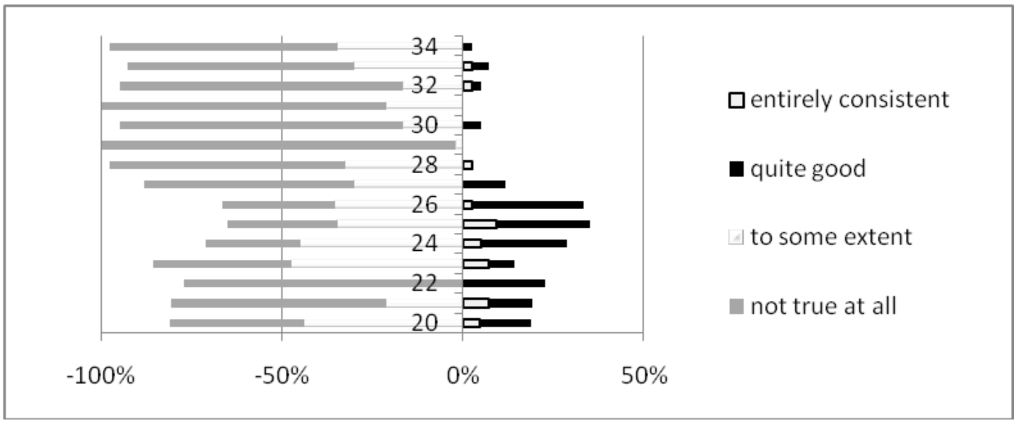

Figure 3. The Mainstreamer group. Example from cluster no. 3 in fig. 2.

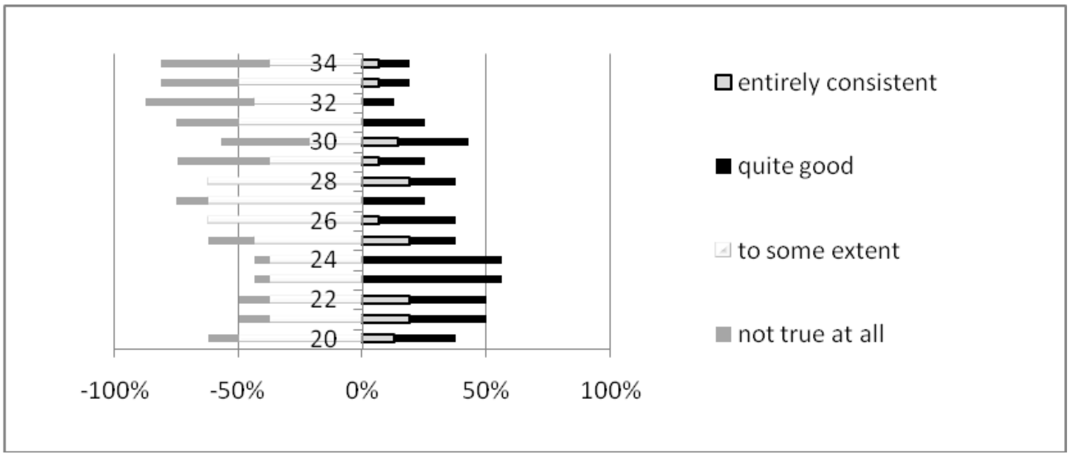

Figure 4. Future solutions group. Example from cluster no. 7 in fig. 2.

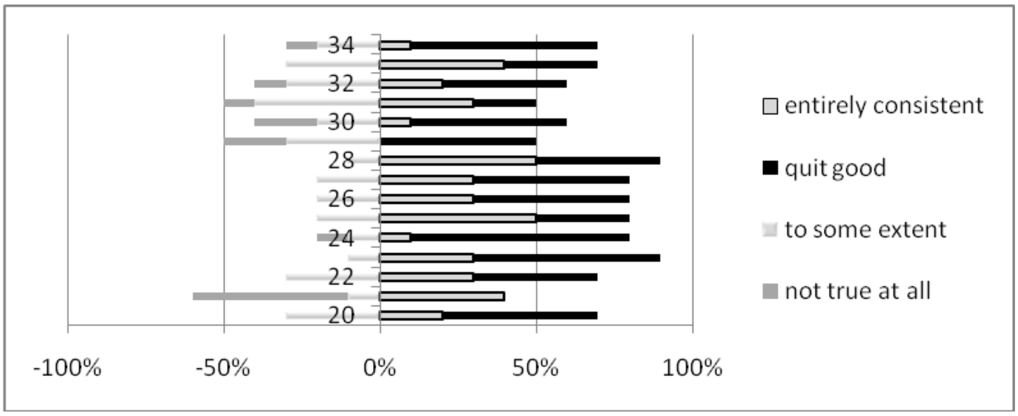

***Figure 5*.** The profile present answers from cluster no. 8 in fig. 2. *The Challenger group.*

A SHORT DESCRIPTION OF THE DIFFERENT GROUPS – WHAT AND HOW ABOUT TEACHING

The Mainstreamer group

The teachers we describe as traditionalists or mainstreamers includes 46% of the teachers. They teach nearly nothing of the more valuating content. However there is one exception; some of them teach about efficiency problems (15% in one of three clusters responding strongly). In another clusters there are three exceptions; teaching about efficiency problems (10% responding strongly), students own energy use (21%) and political issues (16%). Teachers in the last cluster teach nothing, without exception, of the more valuating content. For all The Mainstreamer clusters, the teacher *do not* let the students be involved and determine the content, work in teams, work in groups with course content adapted to events in society and media and they do not let sustainable development influence the content. They do not work thematically or give students space to discuss and evaluate society's issues.

Future solutions group

The group we call *the future solutions group* includes 39 % of the teachers and have clusters characterised by technology optimism, environmental issues respective teaching based on students experiences. One cluster teaches mostly strategies for the future, a large amount of solutions for the future and efficiency problems. But also about the students own energy use and economical aspects. Another cluster teaches about future solutions but also both efficiency- and environmental problems. The teachers in two clusters use to teach thematically and they want students to develop for citizens to have a good understanding for energy issues. They want to encourage their students to choose further studying in energy technology field and they let students discuss and evaluate society's energy issues. In this future solutions group we also find a cluster with teachers assuming the students experience and base teaching on student's discussions.

The Challenger group

This group consists of two of the clusters, totally 14 % of the teachers. The most clear challenger group includes the teachers that teach all of the more valuating content, 60% - 100% of the teachers responding strongly on every statement (related to level D, E and F in table 1). Sustainable development and actual issues in society influence their physics teaching. This group also includes teachers in one cluster that teach almost all of the more valuating content with only a few exceptions; some ethics and politics (only 12% responding strongly).The most clear challenger cluster also have students work thematically, in groups, with actual projects and they let students discuss and develop their own projects, see figure 5.

DISCUSSION

Generally the physics teachers in upper secondary school, physics A course, refrain from subject content dealing with context related to the external environment, energy flows in which human activities are included and context of policy-making, vision, human values etc.

The study resulted in "common features" for all physics teachers and their teaching as answer to the research questions about what and how they teach. These "common features" can be described as: The curriculum is steering the teaching, A standard text book in physics is used, The teaching is led by the book and the teacher deals with typical tasks at the whiteboard, The students do calculations individually and as homework, Group work is common for special issues: dealing with tasks from the textbook or laboratory work. Some teachers remain in these features within their teacher profession (meaning their pedagogical development and in their will to include issues of the society).The cluster analyses shows that these teachers correspond to a clear discernible and dominant group of teachers. But the analysis also shows that there are two other groups with descriptions including more than “common features”.

We can, relating to the research questions, say that the three groups diverge about the *What – question* but have more in common coming to the *How-questions*. For example the teachers appreciate group work and discussions in the classroom, but here we also meet some sort of limit of what is appropriate. Most of the teachers let the students discuss tasks from the text book about how they understand basic concepts and laws. It is not common to focus on the students themselves to determine the content of teaching, to connect the content to the current issues and to let students assess different energy solutions which are important ingredients in teaching for sustainable development.

The physics subject can be seen as a homogeneous, largely characterized by the ideal of scientific knowledge that one can observe and understand the proper laws of regularities in nature. This view is also illustrated as common among all physics teachers in this study as nearly 100 % of them report that they go through basic concepts, relationships and physical laws in their teaching. But with this study we have shown that there are physics teachers who teaches energy differently in the sense that they select a wider topic content compared to the "traditional" and that they include other teaching methods. These Challengers seems within the frame provided for the teaching of Physics A (curricula, textbooks, etc.) carry out a teaching including a valuating content, systems thinking, problem recognition, etc., without giving up on factual knowledge. The Mainstreamer group has an more internalistic view on their physics teaching while the Future group and the Challenger group can be described as having a more externalistic view (Frängsmyr,1984; Sjøberg, 2005). We connect these descriptions of teachers views (internalistic or externalistic) to Roberts (2008) two visions (I and II) about science education. The Challenger group looks on physics as something useful for both higher education and membership in society and furthermore important for insights about sustainable development. The Mainstreamer group teaches physics in a traditional way and give the students who find physics easy and interesting what they want.

In a coming paper the study is to proceed with these teacher groups and explore who they are and why they do what they do. Responses are sought both in the analysis of the questionnaire, and the analysis of the various fields which affect school physics such as politics by the governing documents, science and technology and science education field.

ABSTRACT

The significance of History and Philosophy of Science (HPS), as a medium used to strengthen scientific education within the population, has been vastly recognized. However, it has only been prioritized with regards to historical and philosophical respects in the pre and in-service teacher programs, giving second place to the sociology of science, which has even been viewed with suspicion by some researchers. We propose that reflection is necessary concerning taking the sociological perspective in science when educating teachers, and we highlight that the sociology of scientific knowledge, and especially the work of Bruno Latour and the "Studies on Science", can have an important pedagogic potential.

Keywords: *History and Philosophy of Science (HPS), sociology of science, Studies in science, Science teacher education, Bruno Latour.*

INTRODUCTION

One of the most important subjects in science teaching research is the debate concerning which ends and aims scientific education should currently strive for, a debate that places scientific competition and scientific literacy face to face, that is to say knowledge about the science vs. knowledge about the culture of science (Matthews, 2000). The History and Philosophy of Science (HPS) approach plays a significant role as mediator in this debate. Yet, when the time comes to incorporate HPS into the science curricula as a means to achieve new goals, other perspectives, such as those contributed by the sociology of science, have been largely overlooked; with a few notable exceptions, the fields of sociology of science and science education have existed in isolation (Cunningham and Helms, 1998).

In acknowledging that in the teacher's pre and in-service programs it is fundamental that science teachers know at least something about the history and the nature of the subjects they teach (Matthews, 1994), preference has been given to the epistemological aspects such as the tenuity of scientific knowledge, methodological plurality, theoretical weight in observation, the relationship between science and technology, science as a historic enterprise socially situated in the passing of time, characteristics of scientific reasoning and the rational reconstruction of scientific theories (Aduriz-Bravo, Izquierdo and Estany, 2002; Erduran, Áduriz-Bravo, Mamlok-Naaman, 2007). All the while sociological aspects are seen as juxtaposed with those of philosophy; sociology is used to distance the normative view of science from a descriptive perspective, the "how science should work" from the "how science really works in our society" (Zemplén, 2009).

The suspicious eye that many science education experts cast on the sociology of science is a product of the image it has within scientists, reflecting the various pressures and controversies it has confronted as a discipline, which in its beginnings decided to keep to the margins of science in order to make impartial, external observations, but that later took a "sociological turn" with which it then became more critical and "interfering" as it turned its interests towards the "social influences" that science has supposedly always been free of and on which it has founded its power and validity.

Initially, sociological research moved around the outskirts of "genuine scientific activity", using weak approaches that limited themselves solely to studying scientific misconduct from the social perspective, a stage known as the "sociology of error". To this initial trend belongs the work of researchers such as R.K. Merton, M. Orstein, H. Brown and D. Stimson, in the years ranging from the 1930s to the 1940s (Solís, 1994). These explanations based on causal powers, and which characterize certain types of scientific narratives, gave direct way for many philosophers to consider "external" sociological explanations to science, justifying a division between the internal/external side of science and in which the "rational", "epistemological" or "cognitive" should be in opposition to the "social" (Rouse, 1991). This tension has propagated to the nature of science, bringing an ideal science against a real science, that of epistemic norms to that of historical practice, that of philosophers to that of sociologists, on a balance scale that as seen previously, is tipped to one side by science teaching.

Laudan (1986) criticised and explained, from a position based on the principle of arationality (a demarcation criterion through which sociology of knowledge can intervene to explain beliefs if and only if those beliefs cannot be explained in terms of their rational merits), this Gordian knot in which sociology has tended to consider many episodes of history of thought irrational (and hence, sociological), that are, according to other models of rationality, completely rational. This tendency strengthens the debate between rationality and irrationality, a clash that according to Allchin is not an armchair intellectual debate but rather a power struggle. "It is about the scope of authority of science. Hence, the discourse typically evokes deep emotions. Under standard protocol, one first declares one's allegiances, so that everyone knows whether to treat the speaker as a hero—or to despair that they have succumbed to some imagined "axis of evil" the roles assigned alternately, according to perspective" (Allchin, 2003: 936).

This conflict, which has a part in the so-called "Science Wars", and because of its purely political connotations and origins should have been kept far from the educational environment, is unfortunately present in science teaching. Thus, a great number of researchers have taken the side of giving the role of the villain to the sociology of science. Slezak (1994a) does not hesitate to declare that the claims of contemporary sociology of scientific knowledge (SSK) bring with them serious, educationally and culturally deleterious implications for the rationale and practice of science teaching, hence, science teachers should resist admonitions to accept the findings of the sociology of science; and at the same time describe the moral and intellectual depravation of the SSK, due mainly to its historicist, contextualist, and relativist view of scientific theories. He also declares that there is little reason to take these views seriously, though their widespread popularity is cause for concern among science educators (Slezak, 1994b). Similar opinions characterised in many cases by associating relativism with sociology of science are shared by other researchers like Irzik and

Irzik (2002); Izquierdo (1996), Izquierdo and Aduriz-Bravo (2003); Kragh (1998); Mathews (1994,1997) and Solbes and Traver (2003).

These positions against the sociology of science are discussed by other researchers who take the responsibility of highlighting certain aspects such as the importance of the sociology of science in describing human relationships, beliefs, and values that pervade science, challenge stereotypes and erode the unwarranted status and permanence of science to stress human and societal components and context (Cunningham & Helms, 1998). As such, sociology should not be considered as opposing science or the scientific world-view, but instead could be used to form the basis of a well-informed view about science (Zemplén, 2009), and for developing informed citizens (Kelly, Carlsen and Cunningham, 1993). Moreover, science cannot be divorced from its human context, since it is, above all, a human activity (Allchin, 2003). In fact some of them have even developed research studies in which they have shown the positive role the inclusion of the sociology of science plays in the classroom and formation of teachers (Barab and Hay, 2001; Cunningham, 1998; Zemplén, 2009).

Cunningham and Helms (1998) state that the considerations which originate in the sociology of science should reach the students, since ignoring these understandings not only misrepresents science, but also differentially discourages certain populations of students from further science study. The mythical image of science as the “impossible” field to which only a few privileged “geniuses” who know mathematics can gain access to can avert students from science as a case study by Calabrese-Bartn and Yan (2000) has clearly demonstrated, a case which could quite easily be that of many students. Some classes in which the sociology of science has admittance can make science study more democratic, thus it should be rated “E”: Essential for Everyone (Allchin, 2003).

How then, do we reconcile this dichotomic position between a sector of science teaching that sees a relativist, postmodern, skeptic, etc. risk in incorporating the sociology of science in the science classroom, and those who see such an incorporation a necessity? More so, when it can be declared that this dichotomy springs from an older one, product of power relations, a political battle, between the rational and the irrational, between the normative and the practical, between philosophy and the sociology of science? How can we make decisions when the conflict gets lost in profound “reflections” that don't overcome the range of rhetoric or the provocation between the two sides? For Allchin (2003) the key is in dismantling the mythic impression that to be “social” or “constructed” is to be irrational or relativist and instead look towards the work of philosophers who, motivated by the feminist critique, have made contributions in trying to understand the epistemology of the sciences from other outlooks. This includes the work of those such as Sandra Harding, Helen Longino and Miriam Solomon, who have shifted epistemic norms beyond the individual, to include the social, or of Andrew Pickering who emphasizes the significance of human agency in the presence of the imminent fact of the impossibility that science occurs without scientists. Also, highlighting the ideas of Bruno Latour, David Hull and Alvin Goldman, who help strengthen the philosophical view of science from a sociology perspective.

For us, the key is in accepting the risk of including the sociology of science as another ingredient in science education, in the same way the importance of philosophy and the history of science have been recognized, as well as in considering the potential of one of its facets that is rarely discussed, but that is necessary in science education: the emotional dimension. For us this aspect can be vastly explored in the work of Bruno Latour and thus we present a few considerations regarding his thought, with the aim that they be a point of reflection and maybe even an inspiration in science teaching.

LABORATORES, CONTROVERSIES, BLACK BOXES AND NON-HUMANS

Taking a tour through the thinking of Bruno Latour implies a movement through different moments in the sociology of science that followed the works of Kuhn. A discipline that instead of studying the reactions between scientists, the reward system and and institutional affiliations, decided to move to showing the fundamental social character of objects, facts and discoveries of science, the sociology of science became the sociology of scientific knowledge SSK (Latour and Woolgar, 1995).

Nieto (1995) describes the SSK as a program of critical research that was not interested in analysing the finished products of knowledge, but rather in the process of their fabrication; it changed from searching for formal criteria of demarcation and legitimacy to setting out to explain in a casual fashion the existence of all types of knowing. Inside this tradition it is assumed that scientific knowledge is a social construction, where science is subject to and depends on the conventions and negotiations, on the interests of individuals and specific communities, and that said conventions and interests can and should be explained. Golinski (1998) explains that for the SSK scientific practice is viewed as having an indefinite lifetime and overdetermined, and that scientists are not obligated by logical deduction of present beliefs or biased evidence to develop their ideas towards a particular direction, being able to make practical judgments that can be sent down to their local subculture where there is an investment of resources and skills in order to reach the ends pursued.

In line with the SSK are the works of Barry Barnes, Donald MacKenzie and David Bloor from the School of Edimburg, who constitute the nucleus of the sociology of science's Strong Programme and with which it's primarily associated, especially by critics such as Slezak. Nonetheless also part of the SSK are the works of Steve Shapin and Simon Schaffer who base their sociological research in the empirical study of controversies instead of in a social traditional history, and that of Harry Collins, one of the pioneers of the investigations around scientific controversies in the 1970s, for whom scientific facts can be explained socially leaving aside the arguments that appeal to the impersonal rules of experimental procedure. The importance of these controversies has been recognized in science teaching (Kipnis, 2001; Mathews, 1994).

For Latour (2008) the study of the innovations and controversies has been one of the first privileged places where it was possible to maintain objects as visible mediators, distributed, referred, by more time, before they became asocial and invisible intermediaries. Latour and Woolgar (1995) explain how the facts are constructed in such a way that once the controversy stops, they are taken for granted, and after the controversies end the unique things that remain are claims lacking author, lacking judgment or polemic and even lacking any reference to the experimental mechanism that generated them. At the end of the controversy one goes from the angriest controversy to the tacit knowledge, the step is progressive and continuous - at least when everything passes with normality, which by all means happens rarely. These authors insist on the fact that “while there are plenty of controversies, nature is never used as a final arbiter since nobody knows what it is or says.

But once the controversy is closed, nature is the decisive arbiter" (Latour and Woolgar, 1995: 94).

Another one of the aspects of the SSK in which Latour has made important contributions is that of etnomeotodological research. The 1976 Bruno Latour and Steve Woolgar's *Laboratory Life*, was a pioneering study in the field of ethnographic studies of specific research laboratories, which indicated a different path towards a sociology of scientists, in opposition to the traditional sociology of science, which limited itself to studying patterns inside disciplines, institutions, ethics, public understanding, reward systems, legal disputes and only with great prudence proposed to establish "some relations" between some "cognitive" factors and some "social" dimensions, but without insisting too much on it (Latour, 2008). This study was followed by the works of Karin Knorr-Cetina and Michael Lynch, at the beginning of the 1980s, the first sociologists who worked in studies of direct observation of the practical works done between experimental scientists. These researchers looked to vindicate the idea that the interactions between small groups are not less "social" than the forces on a large scale (Golinski, 1998).

These works, in the core, implied a redefinition of the term "social" which now dealt with different phenomena from the evident influence of the ideology, the scandals or macroinstitutional factors of science, factors that scarcely explain the fact that science's social character is explained in the idiosyncratic, local, heterogenous, contextual and multifaceted character of the scientific practices (Latour and Woolgar, 1995). For Knorr-Cetina (1981) there are many surprises that await us when entering a laboratory to study a group of scientists. The idea that this enterprise can be easily defined in some idealised epistemologic terms is refuted, this preconception crumbles when the ethnographer is able to see that the success in making things work is much more mundane than that of the search for the truth, which is never finally reached. Ethnographic research is a realistic task that tries to truly represent the social order of life in the laboratories and research institutes just as they are, this approach is much different from trying to explain science macrosocially since it allows us to understand the contingent and contextual features of its products.

When entering the laboratory, ethnographers were faced with the fact that the rational/social dichotomy was obsolete, that the distinctions between the cognitive and the social, the technician and the professional, the scientific and the non-scientific, were erased in scientific practice constantly; that the traffic between the social and technical or scientific areas was also subject to scientific negotiation, that it could be more clearly glimpsed if the research was directed towards scientific production on course before being directed towards its historical descent, and so the emphasis was put on considering scientific products like the first and the more important result of the "cognitive" operations, which are mediated by a social process of negotiation located in time and space, instead of on the taking of an individual logical decision (Knorr-Cetina, 1981). The main idea was that "scientific activity was not 'about nature', but a fierce fight to construct reality and the *laboratory* was the place of work and the assembly of productive forces that made possible such a construction" (Latour & Woolgar, 1995: 272). Many of these points have been criticized widely by Slezak (1994b), but as Alchim (2003) suggests, it is now the hour to stop interpreting that everything that contains the terms social or constructed implies irrationality or relativism.

His ethnographic experience allowed Latour to understand that the realm of the construction of science goes beyond the walls of the laboratory and the rising dichotomy between the micro and the macrosocial. Thus, in *Science in action* (Latour, 1987), he presents the bases of his new program: *Studies on Science*, that constructing on and extending the SSK bases, distanced itself from the radical way of the sociological project and it decided to go beyond being a reflection on science to include the general problem of the social order (Domènech and Tirado, 1998). In later works, Latour has extended his questionings and explanations about the total objective of the social explanation of scientific practice, suggesting neither the aim of the explanation nor the categories to which usually the sociologists appeal would have to be maintained. Latour demands "a turn more, after the social turn", that become real in his program (Golinski, 1998).

The program of Latour describes how the practices in which scientists and technologists are involved reshape the social world at the same time as they create natural knowledge, the reason for which it is unsuitable to invoke sociological categories to explain scientific practice. Instead of taking care of those overambitious causal explanations, the analyst must simply "follow" science and technology professionals in the way they manipulate material, social, and linguistic entities (Golinski, 1998). For Latour (2001) the *Studies on Science* are able to reveal, *a posteriori*, all the work that scientists and politicians had to do to become themselves in a weave inextricably united; the work of the "social" researchers does not consist in affirming *a priori* that "some connection" between science and the society exists, since the existence of this connection depends on what the actors have done or ceased doing to establish it. *Studies on Science* simply provides a way to disclose this connection when it exists.

In the proposal by Latour (2001), one that is not totally sociological, but neither totally philosophical, the scientific adjective is the one that defines access, by means of experiments and calculations, to entities that in the beginning did not have the same characteristics as humans do, here science changes entities that at the outset are alien to social life and which soon go little by little to being socialized (the nonhuman ones), starting to live between us, through the bridges tended by the laboratories, the expeditions, the institutions and others, just like the last historians of science have very frequently described. For Latour, the discussions about science have became to be questions over *logic* (is it a straight or curved path?) from *sociological* questions, (is it a more or less solid association?) where it is possible to study how the causes and the effects are determined, which elements are related to each other, how large and resistant the bonds are, among others. Latour calls sociological issues to answer these questions and the only thing that is said to be known about these trajectories is where they go, how many people cross them, with what type of vehicle they travel and if they are comfortable to travel, not if they are correct or if they are mistaken.

This process of "tracking" breaks down the idea that scientific speech is purely literary or fictitious owing to the possibility of resorting to the laboratory instruments that produced the original "inscriptions" represented in the texts. It is possible to see also how these instruments are "blackboxed" and soon go from user to user, increasing their authority as long as they move away from their place of origin. In the eyes of Latour the facts and the machines are transmitted in the same way, going through the chains people tied through networks that make the movement from local knowledge to *technoscience*'s labs around the world possible and that allows the reformed world which reassembles the special devices of which the material artifacts are done to be seen. Hence, that the facts and the machines are able to survive in a world beyond the walls of the laboratory (Golinski, 1998).

For Latour (1987) the “solid facts” or the “highly sophisticated machines”, or the “powerful theories” or the “unquestionable evidences” are black boxes. All these terms that allude to strength and power, indicate clearly the immense number of associations reunited in these boxes, so out of proportion, indeed, that it is what maintains the multitude of allies in its place. The impossible objective of opening the black box becomes possible (if noneasy) if the researcher moves through time and the space, until he/she finds the controverted subject in which the scientists or the engineers hardly work. Thus instead of locking up the technical aspects of science in that box and looking for its social prejudices and influences *after*, it is more favorable to be present *before* the box is closed and it becomes a blackbox. The black box, that simplifying device about which we did not need to know more than the entrances (inputs) and the exits (outputs), must be opened, without paying concern to the how controversial its history is, how complex is its operation, or to the extensive, commercial or academic, network that supports it.

So, the important choice is to make the entrance through science and technology by the back door of science in-the-making, and not by the more imposing of processed science. Latour in *Reassembling the social* explains: “The process of “making of” any enterprise offers a vision that is sufficiently different from the official. Not only it takes to us behind scene and it makes us know the capacities and the tricks of the professionals, but also it offers a rare vision of how it is that a entity emerges from the nonexistence when its temporal dimension is added. Even more important when one crosses a construction site undergoes the disturbing and exciting sensation of the things could at least be different, or that still they could fail; sensation that never is so deep when one faces the ended product, by beautiful or impressive that is” (Latour, 2008: 132)

LATOUR FOR THE SCIENCE TEACHING

Of the works of Latour, that as a group of professors of chemistry interested in the Didactics, we have been able to read, to analyze and to enjoy there are three aspects that we considered valuable and that can be exploded in science teaching: 1) The implications to work shoulder to shoulder with the scientists, 2) The role of the historical reconstructions, the “black boxes” and their relation with the contents of science textbooks and 3) The empathic and affective implications to grant agency the nonhuman ones.

Latour confers a great importance to the practice of science and to working closely with the scientists. From his two-year stay in the Salk Institute with a group of investigation in neuroendocrinology directed by Roger Guillemin, who would later go on to gain the Medicine Nobel Prize in 1977, and that is documented in *Laboratory Life,* and from his expedition in the region of Boa Vista in the Brazilian amazonian forest with a group of edaphologists and botanists who carried out a study on the dynamics of the vegetation and the differentiation of the ground that appears in the second chapter of *Pandora'a Box*, Latour describes, analyzes and establishes relations about the complex that is science and the scientific work.

The reading of those two texts mentioned previously motivates us to know the scientific work *in situ*, to think about science like a process that can be very local and simultaneously have unsuspected reaches, and first of all it motivates us to leave the classroom to go in search of the scientists, those characters who move like managers or administrators, but who also can be in front of “strange” equipment and their registries, while they make political decisions that can guarantee the continuity of their projects. Volante, de Almeida and Queiroz (2007) explain how after reading a few chapters from *Laboratory Life*, a group of students change their conception that to be a "scientist" is "to be in the laboratory" and understand the complex range of activities that a scientist must carry out along with purely experimental work.

To work shoulder to shoulder with the scientists, as Barab and Hay (2001) describe when presenting the results of the project Science Apprenticeship Camp (SAC), can be a way to engage students in authentic scientific inquiry, to allow them to gain understanding of the communal nature of science, and to facilitate the adoption of ways to perceiving and interacting with the world that are consistent with those of real scientists. To work with the scientists changes the conception it means to learn sciences, moving from the memorization of decontextualised facts and skills described by the professor or texts to the appropriation of the socially contextualised practices of a community. Moreover, this direct emotional relation with science can help to break certain myths, those that create abysses between an idealised science and the students and teachers.

With just seeing what scientists do and how they do it, and trying to track down where all the elements tied with their work go and come from, (resources, equipment, personnel, institutions, allies, molecules, bacteria, etc.) it is possible to conceive the complexity of science and to associate it with the networks with which Latour has tried to explain it. The important thing in this point is: *that real approach with the scientists and all its advantages (including the emotional one that consists of recognizing the scientists as human beings) should be considered like part of the sociological component in the pre and in-service programs,* and also, we consider the fact that the experience of the scientific practice can serve to reinforce, thanks to the discussion with who makes science, the epistemic concepts as Allchim (2003) asserts, that is to say, that through the scientific practice sociology and philosophy are complemented, and so with certainty, any effort that is made in this sense will have a positive yield in the classroom.

With respect to the second point, we want to point out that certain claims done by Latour must be considered in the sciences education: the use of the historical reconstructions and the way these are presented in science textbooks. Important aspects arise from his analysis, about the history of science, the protagonists of that history, how it is made official, and how it is sterilised and packed in “black boxes”.

There are two historical cases on which Latour has written widely: one on the scientific controversy between Louis Pasteur and Felix Pouchet and one on the entailment of Frèdèric Joliot with the project for the constructing an atomic reactor in the heat of World War II. Both cases are presented in the History of Science, edited by Michel Serres (Latour, 1998a; Latour, 1998b), but they have been boarded from different approaches in other publications (the case of Pasteur in the Pasteurization of France (Latour, 1988) or the Pandora's Hope (Latour, 2001) for example). The reading of these texts would have to be essential in any pre and in-service program, because it provides an interesting discussion about the role of controversies, specifically when the times comes to analise the history that appears publicly, a history of winners, great men (no women, of course) and of heroes.

Latour and Woolgar (1995) point out that when researchers (especially historians) only address science products, the facts, they have the easy task, that is, “they arrive after the battle and they only need a reason to explain the failure that leaves defeated in the controversy” (Latour and Woolgar, 1995: 97). A claim that already had been done by Ravetz

(1973) when he affirmed that the history of a controversy must be carefully processed not to present the victorious side (retrospectively) of the resulting theories, like lawyers for the obvious, while the losers are slandered, and at the same time compelled to allow their failures open their eyes to the truth, and so the task of the history of science becomes re-encountering the victories that lead them to the establishment of the standard knowledge in science textbooks.

Latour and Woolgar (1995) explain: “In a certain sense the historical explanations are necessarily literary fiction. Just as it appears in textbooks, the historians can move freely through the past, own knowledge of the future, have knowledge of the future, have the capacity to examine scenes in which they are not present (and never they will be), have access to the motivations of the actors, and (as God) be omniscient and omnipresent, able to judge the good and the bad. They produce histories in which a thing is the “sign” of another one and in which the disciplines “bloom”, “mature” or are “rejected” (Latour and Woolgar, 1995: 121). The history of the science that we use in our classes and that is present in the training materials, in some cases with the aim to motivate our students, in order to present hard sciences in a smoother way, more human and therefore to make it more popular, as indicates Kragh (1992), can not only reduce the historical dimension of science to the chronological level or anecdotal but it can, on the emotional level, transmit an idealised image of science where there are only winners and where the beaten ones do not at least have the right to being mentioned, an image of science which for some can be injurious between students. *The pre and in-service teacher programs would not have to be satisfied with teaching the advantages of historical reconstructions, a sociological critic about them and of how they appear in science textbooks is necessary.*

Finally we want to mention the microbes, “the microbes of Pasteur”. Latour describes them like decisive allies in the war between Pasteur and the spontaneous generation, a war that this one lost between 1860 and 1864. Latour unlike other sociologists of science confers it a special role in the scientific activity to which denominates the non-humans. Molecules, microbes, diesel engines, neutrons that in a deterministic moment in the scientific work have been fundamental. Non-humans that are also mobilized in course of the controversies and if lacking would generate “different histories”.

Latour gives agency to them, a concept that until then had been exclusive to humans and in addition it emphasizes how highly social they can be thanks to science, allowing them to leave the place they where always hidden in and and to go to live between us. To read the texts of Latour that speak of Pasteur and his microbes is an exciting experience that although certainly resembles a novel story in some cases, (sometimes science is thus), it allows us to see the history of the science in another way. It is simply impossible to not “fall in love” with the microbes as the story advances. That empathic aspect that is shown recognizing that science is not only one human enterprise but there are “others” that take part in it and constitute it “socially” is something different from that which has been usually sold to us, it is what we highlight as one of the most important points in the work of Latour.

It is important from the point of view of whom and how we are today teachers and students, very different from the students and teachers of fifty years ago for which educative systems were designed in which still we are immersed. “Postmodern” students and teachers living in a world which surround us by the “products” of science, a world in which the differences between science/technology are no longer so evident, where the barriers between all the categories and dichotomies we once had are lost almost completely, a world where our students do not want to know of science and in which a little empathy and affection, by those nonhuman could even be the key to make engage them in science.

In the end what Latour teaches us is that next to those solitary scientists whom official traditional history has been in charge of to present to us. Locked up in its laboratories are immense amounts of people, resources, institutions and obvious non-humans that today make possible that their names be what they are, is only necessary to investigate better and to follow the threads that science is leaving its step. It also teaches us to think about science as something more complex beyond all the "black boxed" theories, concepts, products and processes and invites to us to know more, to want to see science like something social, just now what someone in the past insisted on separating is the hour to return to reunite it. *Any teacher program of NOS would have to be directed to motivate the teachers, to reunite again nature with society.*

CONCLUSIONS

In this work we have attempted to give a tour of the thought of Bruno Latour, along with the development of sociology of science in the Pos-kuhnian Era. In spite of not basing our claims on own empirical research we consider, through theoretical reflection, three aspects of the work of Latour to have great potential in pre and in service teacher programs:

1. Personal experience of teachers with scientists in the setting where science is carried out
2. Critical sociological reconstruction of the history of science, especially of the one which appears in textbooks
3. The need to understand the enduring relationship between the social and the natural

These three topics present in the work of Latour are expressed in the emotive, a dimension that has been consigned to the second plane in science education and that should be recovered in the teacher programs with the aim of drawing closer and demystifying the science with which we want our students to engage.

WHAT DO PRE-SERVICE TEACHERS THINK ABOUT VISUALIZATIONS AND IT'S USE IN CHEMISTRY INSTRUCTION?

ABSTRACT

In science and science education the interest and the use of visualizations has increased greatly in recent years (Gilbert, 2005; Ferk & Vrtacnik, 2003). The reasons for this growth are very well known and consensual: the exponential rise in the memory capacity of personal computers and the associated investment made in software development and the increasing belief that visualizations some how help pupil's learning. So in this new teaching environment, educators introduce several types of visualizations in their own classes with the purpose of getting better learning results. On this work we try to understand what a group of pre-service teachers think about the general use of visualizations in chemistry instruction and the specific reasons and thoughts that underlie their own choices as teachers in a mini-course that they presented to middle pupils at S. Paulo's University, Brazil. The research indicates that these pre-service teachers had a weak theoretical knowledge about this issue; their conceptions are superficial and based mostly on their experience as pupils. We can also say that based on recent research (Wu, Krajcik & Soloway, 2001; Gilbert, 2007; Briggs & Bodner, 2007), they show misconceptions about this issue, such as: don't recognize the cognitive value of visualization or the knowledge of codes and conventions of representations. Therefore there is a high risk of using visualizations inappropriately and it will lead to serious fails in pupil´s apprenticeship.

Keywords: *Visualizations; Chemistry instruction; Teacher's conceptions.*

INTRODUCTION

The use of visualizations in chemistry instruction became a new field of research. In the last years, four very different groups of people (computer software specialists, scientists, educationalists and cognitive scientists) have promoted the development, the discussion and the use of visual tools in sciences instruction (Gilbert, 2007), nerveless research evidences are only in the beginning. There are more questions than answers. The role of models and visualization in science and science education has been discussed in the last years in several studies: what to study, how to do so, what constitutes good practices, or how to evaluate the outcomes of that practice are some of the challenges that researchers have faced and will continue to face in the next years.

There is a central topic that often crosses these studies which is the definition of the term "visualization". According to Gilbert et al (2008) there are two conventions, in convention 1, visualization is a verb (to visualize something is to mentally act on it), in convention 2 visualization is a noun (visualization is something in the public realm). Inevitably, there are also studies that cross the two conventions, for instance, studies about “visuospatial thinking”.

We found literature approaching this issue in the sense of convention 1 that dealt with questions such as: How is a visual representation turned into knowledge? What are the mental processes that are involved in attaching a meaning to a representation? What mental and brain processes are involved in “seeing”? (Reiner, 2008). Other authors (Gilbert, 2007; Rapp, 2007; Rapp & Kurby, 2008; Briggs & Bodner, 2007) also present their ideas about these concerns. Gilbert refers the importance of developing “metavisual capability” or “metavisualization”, the acquisition of fluency in visualization and the making of meaning for any representation (Gilbert, 2008). This author suggests that this development could be done by general good practice in the use of representations by teachers and in textbooks and by the specific cultivation of the skills involved (Gilbert, 2007). For Gilbert the skills involved are: being able to move fluently between two-dimensional and three-dimensional representations of a given model (translate); being able to mentally change the perspective from which a given three-dimensional representation is viewed (rotation); being able to operate on the representation itself, particularly in terms of taking mirror images of it (reflection and inversion). This author also suggests that in order to become metacognitively capable in respect of visualization, pupils should:

- *Know the conventions of representation, both for the modes and major sub-modes of representation that they are likely to encounter;*
- *Know the scope and limitations of each mode and sub-mode i.e. what aspects of a given model each can and cannot represent; (Gilbert, 2007, p.21)*

One problem with this approach is the difficulty to evaluate the pupil’s status in respect to metavisualization, in order to solve this problem Gilbert suggests the use of some available tests for assessing competence in some of the key aspects of visualization at the lower level of metavisualization. In this lower level:

> *‘An individual is capable of: reflecting about many features of the world in the sense of considering a comparing them in her (sic) mind, and of reflecting upon her means of coping with familiar contexts. However she is unlikely to be capable of reflecting about herself as the intentional subject of her own actions.’ (Von Wrigth, 1992) (p. 60-61) (quoted in Gilbert, 2007)*

Assessing performance at the upper level of metavisual competence could be done by interviewing the pupils as the tasks in the tests are being completed. At the upper level, an individual is capable:

> *‘Reflecting about one’s knowledge or intentions involves an element which is absent from reflections about the surrounding world. Self-reflection presupposes, in the language of mental models a ‘metamodel’: in order to reason about how I reason, I need to access to a model of my reasoning performance’ (Von Wrigth, 1992) (p. 60) (quoted in Gilbert, 2007)*

Using another approach Rapp and Kurby discuss the importance of the construction of mental models by the pupils. Without these models learning becomes very difficult, especially in chemistry. In Rapp (2007) this author discusses the construction of mental models related directly to the use (and potential) of visualizations as educational methodologies. Rapp presents mental models as abstract representations that store the spatial, physical, and conceptual features of experiences, useful for retrieval in the service of problem solving, inference generation, and decision making. He goes deep and points:

> *'In summary, mental models are internalized, organized knowledge structures that are used to solve problems. They are encoded with respect to the spatial, temporal, and causal relationship of a concept. They can be run to simulate that concept, in order to assess alternative viewpoints and consider possibilities not readily available or apparent.' (Rapp, 2007, p. 46)*

In Rapp & Kurby (2008), these authors try to make the connection between 'external representations' and 'internal representations' and relate these studies to educational situations. How to draw effective visualization experiences that help pupils internalize those visualizations and achieve learning? For these authors the solution maybe:

> '*By designing 'visualizations' in ways that align with the nature of memory, it may me possible to more effectively help pupils understand those challenging concepts. In addition to finding better ways for pupils to learn complex concepts, 'visualizations' may also aid pupils in dealing with unfamiliar, but potentially related, problem solving situations.' (Rapp & Kurby, 2008, p. 48)*.

In this line of studies we find also two authors (Briggs & Bodner, 2007) that point out again for the construction a mental model. On their qualitative research, while working on each tasks the participants were encourage to verbalize what they were thinking at the moment, they conclude that when participants were working on a mental molecular visualization/rotation task they invoke components of a mental model. They identify four static components: referents, relations, results and rules/syntax, and a fifth dynamic component: operation. They refer also that participants use the constructed mental models as mental tools to complete the task. From these outcomes these authors also claim that:

> '*Improper visualization may cause flawed representation and lead to incorrect results. This is an important lesson to teachers. We must be very careful of the manner and precision with which we scaffold our pupils as they construct their mental models of domain-accepted concepts. A flawed mental model can have an impact on reasoning beyond what one might expect.' (Briggs & Bodner, 2007, p.70)*

These are some of the key ideas that we found in literature, several other authors and studies work on this trend providing insights into understanding the process of visualization, and into designing the learning environments in a manner that is adaptive to the behavioral and brain processes known data.

Like we mentioned before, there is another trend of research that uses the term visualization in the sense of convention 2, a noun, something that has been placed in the public realm in either a material object, visual, verbal or symbolic form. Here we found several studies (Wu, Krajcik & Soloway, 2001; Ferk et al, 2003; Santos & Greca, 2005; Tasker & Dalton, 2006; Savec, Vrtacnik & Gilbert, 2007; Kozma & Russel, 2007b; Arroio & Honório, 2008) that by using a different approach try to evaluate the use of different kinds of visualizations in chemical instruction. Most parts of these studies are only quantitative and through a series of specific tests they try to evaluate the pupil's apprenticeship and indirectly the effectiveness of the visualization used.

Therefore, we began to encounter some studies where a component of qualitative research is introduced. The aim of this introduction is to obtain rich information of how pupils develop an understanding of chemical concepts while using visualizations as helping tools in learning. A great part of these tested visualizations are software with virtual 2D and 3D images and in a few cases animations and simulations or combinations of various representations (e.g. concrete three-dimensional models, virtual computer models, static two-dimensional computer models, stereo-chemical formulas).

We also found an interesting work that talks about the need to develop “representational competence” (Kozma & Russell, 2007a) in the pupils. This term is related to the skills and practices that are needed for a person to build and use a variety of representations or external visualizations, to think about, to communicate with their peers, etc. These authors also present an investigation (Kozma & Russell, 2007b) using five chemistry multimedia visualization projects using different approaches. The authors conclude that all five projects shown an improvement in the learning of chemistry concepts and development of scientific investigative process skills. In this work the authors left some recommendations for visualization-based instructional activities which we highlight: there are no carefully designed experiments that tell us when it is best to use animations versus still pictures or whether dynamic molecular models are better than physical ball-and-stick models. There is no data about the precision of how these various media can be used together and when is best to do so. Now days, all these practical issues are left up to the judgment of instructors and instructional designers.

According to what we have referred before, we also find studies that cross these two conventions and try to examine the role of visuospatial cognition in chemistry learning (Wu & Shah, 2004). This interesting work shows that visuospatial abilities and more general reasoning skills are relevant to chemistry learning. They also conclude that some of the pupil’s conceptual errors are due to difficulties in operating on the internal and external visuospatial representations and some visualization tools have been effective in helping pupils. This study also presents five principles for designing chemistry visualization tools: (1) providing multiple representations and descriptions, (2) making linked connections visible, (3) presenting the dynamic and interactive nature of chemistry, (4) promoting the transformation between 2D and 3D, and (5) reducing cognitive load by making information explicit and integrating information for pupils. With these five principles the authors expect to enable us to help pupils understand chemistry concepts.

In the mean time teachers introduce these tools in their classes, sometimes without the necessary and desirable training on these subjects therefore contributing to the unsuccessful learning that has dominated the field during the past years. Many of the concepts studied in chemistry are abstract and are inexplicable without the use of analogies or models, so visualizations are here to stay and we think instructor’s use will be more as an educational methodology.

METHODOLOGY OF RESEARCH

We adopted a qualitative research in our study, applying a semi-structured interview to groups of pre-service chemistry teachers from a Chemistry Teaching Methodology II class from University of São Paulo (USP), São Paulo, Brazil. During this class these pupils had to prepare a mini-course to offer to secondary school pupils. This mini-course takes two days, and these graduates are responsible for the entire mini-course (subjects, methodology, assessments). At the end of these mini-courses we applied an interview to each group with several questions. The first set of questions (nine questions, common in both interviews) were more general and aim to know what conceptions they have about visualization and it's use, the next questions (three for the first group and four for the second group) were about their own choices of visualization to be used in their mini-course classes and one last common question about misconceptions.

According to Bogdan and Biklen (1994), the use of interviews is the best approaching tool to study people that share a particular feature. What they share between them will be revealed when they talk about their perspectives rather than when they are watched during their activities. Here we present the outcomes of the interviews made to two different groups of graduates. Each group was composed of 7 graduates that planned, presented and evaluated two lessons of secondary school pupils. The discourses' analysis was made with the contributions of Michel Foucault's theory of discourse.

RESULTS OF RESEARCH

As we mentioned before each group answered to a first set of questions with the purpose of finding what they think, understand about visualizations and its use in a general way. Here we have to point out that we use the term visualization in these interviews in the sense of the convention 2, a noun, something (visual) that was used for the graduates in the presented lessons.

First group: general questions

The first group chooses to plan a mini-course about a content of the secondary school curriculum 'Separation mixture methods'. On each question we are going to present the key ideas revealed by the group, so to the first question "Why do you decide to use visualizations in your mini-course?" The graduates answered that they were looking for something to start the lesson, in order to make an introduction with impact. They also said that they were searching for pupil's previous conceptions about this content, and visualizations seem to them a good way to help pupils to retrieve information. They also referred that the use of related images about the issue on discussion provides pupils with some information, but not all the information, forcing them to remember what they already knew about this content.

The second question was "What kind of visualizations do you use?" They said:- "2D statics images"-,- "Photos"-. The third question was "Why do you choose this kind of visualizations?" They answered: "Because of the simplicity", "Because, it was easy to build the sequence of transformations in each separation method." Related to what they said before, they only want to have some starting points with little information, nothing dynamic or too complex.

The fourth question was "The visualizations choice was engaged with some epistemological, ontological or axiological conception". To this question graduates showed same difficulty in understanding what was really asked. After some explanations about the meaning of these three terms the graduates said: -"No, we didn't think about that previously." They revealed that they were more concerned about the verbal discourse, the best image's sequence, than the images itself. They also referred that in respect to the values (axiological) they used "*good sense*" in order not to offend anybody, but they agreed for instance that in some images they showed some food brands. They said that the images were "clean" and for them they don't fell any effect when they watched these images and if it caused some impact on pupils it wasn't their intention, but once again they were more concerned with the sequence than with each image.

The next question was "Do you feel that the type and the quantity of visualizations used was suitable to your purposes?" They answered that there was some excess, and perhaps they should have changed a few images. They feel that it was one specific image that caused some confusion in pupils, and that they should have thought better on this choice. They also referred that even with some bad choices they achieved their goal (retrieve information using visualizations).

To the sixth question "The visualizations were there to illustrate or they hold information?" They answered that they hold some information. They wanted pupils to use the images as helping tools simultaneously with the verbal discourse to achieve the concepts of the content. Most of the images were related with the pupils quotidian, trying to keep their attention.

To the seventh question "Do you think that the use of visualizations must be framed with verbal information? Why?", They immediately answered -"Yes, and in a meaningful way". One graduate insisted on the idea that they should be complementary, and others mentioned that it was always necessary to have some kind of verbal information in order to guide the message that we pretend to pass. These graduates also referred that if there is a lack of framing between visualizations and verbal information it could create a conflict in the pupils' mind.

The eighth question was "Do you believe that the used visualizations helped the pupils' learning? What data do you use to answer this question?" The graduates answered -"Yes"- they mentioned that the images were used to contextualize the issue. One of them said – "the image made its role"- , and other said that in pupils' activities in class they used images a lot.

The ninth question was "Do you feel as teachers that the use of visualizations some how help your teacher's role. Why?" First they said that it helped to get their attention because they think that the more senses (audition, vision) they use, the more attention they get. One graduate said that maybe the visualizations make the teacher work less hard, others add that the visualizations make things "easier".

First group: specific questions

The next three questions are about their interventions and choices on the mini-course, so the tenth question was "On your mini-course when you approached the attainment of cooking salt you use one sequence of three images without any verbal discussion of the transformations between each image. What do you think that the pupils thought in that moment about those transformations? They answered that even they knew that probably some pupils may not know the right transformations, later when they discuss this they will have the opportunity of work in some misunderstandings or alternative conceptions.

The eleventh question was "During your mini-course one of you said to a pupil - "Ethanol is a molecule."-, without showing any visual element or any question with the intent to inquire if she knew the meaning of "molecule". What do you think that this pupil may have "imagined", or what kind of concepts she retrieved from her memory (if she already had something) in the moment that you introduce this abstract identity from the submicroscopic world of chemistry?

The answer was that even their perception was that the pupil didn't understand yet the molecule concept they felt that they should give a "scientific explanation". Later, they hope that someone could explain her better what a "molecule" is. They added that when they realize that she didn't know what a molecule is, one of the graduates tried to relate to quotidian's uses so at least she could identify this substance. After some group discussion about this intervention they agree that their lack of experience as teachers led them sometimes to have difficulties when they have to deal with unexpected situations.

The twelfth question was "On your mini-course sometimes you use the expression - "Are you seeing?"- applying to pupil's abstraction. How can you be sure that the pupil "saw" what you wish he had seen? They agreed that sometimes they "fall" in this situation, and when they realize (sometimes by the look in the pupil's face) that they weren't seeing anything, they try to make them externalize their thoughts in order to help them in a better way to achieve the concept.

The last question was again a general one "What consequences could arise from pupil's misconceptions on the teaching/learning process in chemistry?" Here the opinions were a little divided. Some graduates think that nothing is definitive, with time and good teachers the pupils will have the opportunity to correct these misconceptions, but others felt that these misconceptions could lead to great problems in future apprenticeships. They argue that all the concepts in chemistry are very connected, and there are some key concepts that compromise the apprenticeship of others. They believe that in some cases this lead to unmotivated pupils because they start by not being able to give meaning to the chemistry concepts.

Second group: general questions

The second group chooses to plan a mini-course about a content of the middle school curriculum 'Solutions and concentration'. As we mentioned before on each question we are going to present the key ideas revealed by the group, so to the first question "Why do you decide to use visualizations in your mini-course?" The graduates answered with several adjectives about visualizations, they said that they are: conspicuous, appellative, inducing. They also mentioned that both themselves and the pupils like visualizations and they are used to watch in their own classes as pupils. They felt that they should do something different. They want to get their attention, create interest and impact.

The second question was "What kind of visualizations do you use?" They answered: a video clip, a TV news (movie) and an animation, and with some hesitation one of the graduates added the red currant solutions that they show at the end of the first lesson as something concrete. The third question was "Why do you choose this kind of visualizations?" They answered that the pupils are used to see that kind of images. In order to explain salt dissolution they needed a dynamic visualization, so they choose one animation. They also said that they think that movement is very important; helps to get and keep pupil's attention.

The next question was "Do you feel that the type and the quantity of visualizations used was suitable to your purposes?" They answered that it was "nice", they felt happy with their own choices. The fifth question was "The visualizations choice was engaged with some epistemological, ontological or axiological conception". On this answer and like on the other group, graduates showed same difficulty in understanding what was really asked. After some explanations about the meaning of these three terms the graduates began to say yes, but their answers were not coherent, clearly they were talking about another perspective. They kept telling what they expected that visualizations could do, and even said that they thought in these issues; nevertheless they couldn't concretize any coherent answer.

To the sixth question "The visualizations were there to illustrate or they hold information? They answered that the video clip was illustrative, the news was "*to make them think*" and the others hold some information. To the seventh question "Do you think that the use of visualizations must be framed with verbal information? Why?" First the graduates answered -"No"- , - "Not necessarily"- , and then they said that they didn't think about that. Some hesitate and said -"Yes"- , a graduate said that if there is some verbal information (written) it could split pupil's attention. In the end the opinions' were divided, some of them said yes, but others still think that it was not necessary to have a framing.

The eighth question was "Do you believe that the used of visualizations helped the pupil's learning? What data do you use to answer this question?" The graduates said "Yes" and they reported only the animation. They said that they applied an inquiry to the pupils before the animation and other inquiry after they saw the animation, and they felt that the pupils have improved their knowledge about this issue. They said that the answers pos-animation were more coherent.

The ninth question was "Do you feel, as teachers, that the use of visualizations some how helps your teacher's role. Why?" They answered –"Yes, all the resources used were necessary." In the case of animation, they felt that it was completely necessary, without them it was very difficult for them to explain to pupils this process. They also added that the concrete red currant solutions they showed were very important, the pupils had the opportunity to make some reflection on something that belongs to their quotidian.

Second group: specific questions

The tenth question was "At the end of your second lesson one of you refers: We are going to present a video that shows what happens when we put salt on water". According to this introduction, what do you think that pupils thought about this phenomenon? First they didn't understand the question, after some explanations, one graduate said -"We didn't say that it was a representation!"-. Now, they all agree that it was a bad approach, and perhaps pupils thought that the animation was a "zoom" that a powerful camera did to the water. Nerveless, some graduates hesitated and said that this approach was not incorrect, it's expected that these pupils already know that in chemistry we always deal with models and representations and in some textbooks they also find this kind of language. These graduates even ask if it was productive to be always saying that we work with representations. They put the question – "The pupils pay attention when we say that this or that is a model?" They added – "We should discuss that they are representations, but it's not necessary to do this every lesson."

The eleventh question was "On the presented animation about salt dissolution, what do you think that pupils identified as the cubic structure of green and white balls? The graduates answered -"The salt"- and then they agreed that they still have a lot of difficulties to make a displacement to the pupil's thoughts and try to see their point of view. They hope that pupils didn't pay attention to the cubic structure.

The twelfth question was "On the same animation, what meaning do you think that pupils gave to the plus and minus signs that were on white and green balls, respectively? They answered that they don't know if they gave some meaning to that signs and that maybe they already know that they represent ions. If they never heard anything about ions, they believe that they just look at is as different kinds of atoms, and that one day they will have the opportunity to work on this concept and attribute some meaning to this observation. They also mentioned that wasn't the moment to discuss this concept and perhaps they pay more attention to the color of the balls than the signs. The thirteenth question was "Do you think pupils related in a correct way to the chemical symbols and the balls that were chosen for its representation?" They said that they didn't discuss this detail with them; they only tried to demonstrate with the animation what happens when you put salt on water.

The last question was again a general question "What consequences could arise from pupil's misconceptions on the teaching/learning process in chemistry? Some graduates answered that the pupils could carry these misconceptions for years compromising chemistry apprenticeship. Others said – "You fail the test." A graduate added that it depends on the importance of the concept, if it was a key concept such as atomic model, it could compromise all chemistry apprenticeship, if not the pupil will have the opportunity to clear up the misunderstandings. One other graduate admitted that it was just when he was preparing some classes that he had the opportunity to clear up some misconceptions, and this could be a serious problem, because sometimes teachers disseminate errors as instructors.

CONCLUSIONS AND DISCUSSION

Analyzing the outcomes of our interviews we can say that these pre-service teachers use visualizations as helping tools that they know by their own experience as pupils, that it can get pupils attention. It seems that they use visualizations mainly to run way from traditional class and second because of their educational value. Although they attributed cognitive value to visualizations, for instance, in order to make abstract concepts easier to understand, the first reason it's to make classes more pleasant.

When they are asked to explain their visualization's choices they show a weak theoretical knowledge about this issue, they aren't yet sensible to the impact of visualizations and they don't know how to use them in a fruitful way. It's clear on their answers that their visualization use is more concerned with the external effect that visualizations cause, than to the internal effects of visualization. They never mentioned the supposed role of (external) visualizations on internal visualizations (mental models) and it seems that they aren't really aware of visualization's *power*. We could say that they use visualizations in a *naive* form. This was very clear when they used the animation; first they never mentioned its use as a representation and second they don't discuss with pupils the codes and conventions associated to every visualization. They expected that like they said "*The images made their role*", and if everybody uses them, so they must be important for learning. They completely forgot that the intended purpose of the visualization and its relation to the referent is obvious for the teacher but sometimes is opaque to the novice pupils (Uttal & Doherty, 2008).

When asked about epistemological, ontological or axiological conceptions in visualization's use, they show some lack of knowledge in this area, even those who said "yes" to the question, like we mentioned before, their answers were not coherent and clearly they didn't think previously on these important questions. Once again on the answers to this question they show that they were more concerned with the verbal presentation, than with visualizations. They don't realize that each visualization convey a lot of information and values that sometimes are a little disguised but they are quickly assimilated by an interested pupil, and instructors must be always aware of these situations. These thoughts are very present when they said that some visualization was used only to illustrate or "to make them think".

A question that made some different opinions appear between the two groups was about the simultaneous use of verbal and visual displays of information. For one group it was clear that visual display must have always some verbal information in order to guide the pupil's perceptions, the other group had divided opinions but most of them said that verbal information was not necessary, in fact it could split pupil's attention. One graduate also said that this display of information should be complementary, but when asked to concretize a little more why, they weren't able to give a direct answer.

These sources differ in the fact that, textual information presents information in a linear sequence, whereas visual information sources provide all the information to the learner simultaneously (Thorndyke & Stasz, 1980; Larkin & Simon, 1987). When we have a textual display, the cognitive processing is directed by the structure of the text, but when we have visual display the processing of information is directed by the learner, so additional attentional processes for acquiring information from scientific visual information is needed (Gobert, 2007). Thus, teachers must be aware of these demands and find knowledge acquisition strategies for acquiring information from complex visualizations in chemistry.

When asked about if they felt that visualizations helped them as teachers and the pupils learning, they all said "yes" in both situations. For the pupils they based their opinions mostly on their perception of how pupils enjoy the images, nerveless one group mentioned that the inquiry that they applied after showing some visualization appears to have more coherent answers and then they attributed this improvement to the visualization use.

For them as teachers, they all said "yes" for several reasons: keep their attention, make "*things easier*", and make abstract things visible. And here we have to notice that one group of graduates almost shows a dependence of visualizations. On the animation's use the group felt that was completely necessary to use the animation. It was as if they didn't know how to explain this process without this visualization tool.

The answers to the questions about the specific choices that they did on their mini-course show us that there is a lack of training both in this area and as teachers. As pre-service teachers they show natural lack of experience, for instance, when they use the word molecule without knowing if the pupil had already internalize this concept, and when they realize that the pupil didn't know what was a molecule, they try to solve this problem giving an example.

Another difficulty that they show and feel it's when they try to see pupil's point of view. This fact is very evident in the answer to the last question; some graduates seem to have difficulties to make the necessary displacement to the pupils' minds. They based the answer on their own experience as pupils and if some how they could clear up some misconceptions, it's possible that other pupils could do too. They aren't yet taking in account the class pupil's diversity and the nature of chemistry concepts. On the other hand they also show a lack of theoretical background necessary for them to apply these new tools with some effectiveness in chemistry teaching. Like we mentioned before there is an absence of some knowledge related to the skills need to give meaning to any visualization.

First they don't show any particular understanding that it is necessary to improve *metavisual competence* on the pupils and that they must know previously the codes of representation, the conventions that underlie the visualizations, and second it seems that some of them begin to believe that visualizations could be a panacea for teaching some difficult scientific topics. We also believe that they don't see the visualization's use as a teaching methodology but just some helping tools that in punctual moments could give some help on chemistry teaching.

These findings reinforce our previous study (Ferreira & Arroio, 2009) where these graduates showed uncomfortable with these issues. In this work we concluded that their training course discusses these topics in some subjects but in superficial way. We also found that their conceptions are not solid, and sometimes even become misconceptions.

"KITCHEN STORIES" - ASSERTIONS ABOUT FOOD AND COOKING AS A FRAMEWORK FOR TEACHING ARGUMENTATION

Erik Fooladi

ABSTRACT

The recent years have seen an increased interest in science education aimed towards the nature of science and inquiry. Within this context, promotion of reasoning and argumentation in school science has come forth as an important field of research. The present contribution is a work in progress aimed at involving pre-service teacher students in work towards development of a cross-curricular framework for teaching argumentation and inquiry. Herein the explicit teaching of Toulmin's argumentation pattern is utilised for students to analyse claims, expand them to build complete arguments and plan open-ended inquiry with regards to assertions (i.e. claims) about food and cooking collected from authentic sources in everyday life, herein termed "kitchen stories". Results from the pilot study indicate that students, starting from the claim, are able to construct complete argument patterns including all the elements given by Toulmin (claim, data, warrant, backing, rebuttal, qualifier), as well as to give suggestions to setups for experimental investigation of the kitchen stories. Possibilities and prospects are discussed of using kitchen stories for the teaching of argumentation and inquiry.

Keywords: *Argumentation, inquiry, open-ended, Toulmin, food, cooking, science, kitchen stories.*

INTRODUCTION

The present contribution describes a work in progress consisting of two parts. Firstly, an account is given promoting a novel framework for teaching argumentation and inquiry in cross-curricular settings, science being the major player. The second part describes a pilot project underway in which pre-service teacher students take part in the initial testing of this framework at University College level. It is argued that the present framework should be of relevance at a wide array of levels across education and research alike. As a byproduct of this, it is demonstrated how Toulmin's argumentation pattern may be applied in a new way in the analysis of assertions about food and cooking, what is herein termed "kitchen stories".

ARGUMENTATION IN SCIENCE EDUCATION

Within the international science education community and among policy makers it has been defined as a major challenge the development of quality teaching methods to promote scientific literacy, focussing not only on *what we know* but also on *how we know* and *why we do so* (e.g. Driver, Newton, & Osborne, 2000; Osborne & Millar, 1998; Rocard et al., 2007).

Consequently, the recent years have seen an increasing amount of research focussing on promotion of various cognitive skills in science education such as talking, reading and writing science (e.g. Wellington & Osborne, 2001) as well as the development of students' competencies in reasoning and argumentation (Driver et al., 2000; Duschl & Osborne, 2002; Erduran & Jiménez-Aleixandre, 2008; Osborne, Erduran, & Simon, 2004a). This emphasis has paved the path for new innovations in teaching for science literacy such as Keogh and Naylor's concept cartoon framework aimed at use in classrooms (Keogh & Naylor, 1999, 2000) and the IDEAS resource by Osborne et al. for promoting teachers' own qualifications in argumentation as well as facilitating pupils' learning of argumentation (Osborne, Erduran, & Simon, 2004b; Simon & Johnson, 2008). It has been advanced that teachers' own argumentation competency and skills are a prerequisite for quality argumentation to be appropriated in classroom discourse (Osborne et al., 2004a), and Simon et al. (2006) contend that within continuing professional development to promote argumentation in classrooms "[…] *it is teachers' initial understanding of argumentation that determines their development […]*" (p. 256). Furthermore, these and other researchers argue that *explicit* instruction of argumentation is necessary in order to efficiently facilitate higher-order thinking and argumentation strategies among teachers and pupils alike. Such explicit instruction might take the shape of teaching reasoning patterns in general (Zohar & Nemet, 2002), or the introduction of specific argumentation tools, such as Toulmin's argumentation pattern (TAP, see below) (e.g. Erduran, Simon, & Osborne, 2004; Osborne et al., 2004b; Simon et al., 2006). Accordingly, there is a need to develop a diverse range of teaching strategies and tools not only directed towards pupils, but also for the development of pre-service and in-service teachers' knowledge and skills in argumentation, in which we anticipate shall be able to carry out quality instruction. These strategies and tools should include an explicit treatment of argumentation and reasoning.

The Toulmin argumentation pattern (TAP) in science education

In research related to argumentation, Toulmin's argumentation pattern (Toulmin, 2003) has gained foothold as an efficient analytical tool for the education researcher in the study of argumentative student discourse (e.g. Erduran et al., 2004; Jimenez-Aleixandre, Rodriguez, & Duschl, 2000; Zohar & Nemet, 2002). In some cases TAP has also been utilised in the explicit teaching of argumentation, in shape of a tool for teachers to gain an increased understanding of discourse in their own classroom (Osborne et al., 2004a) or the epistemic nature of their own discipline (Simon et al., 2006), or introduced directly to the pupils as part of instruction on nature of science topics (Osborne et al., 2004b). In Osborne's (2004a) words: "*the use of these features of TAP offer teachers a richer metalanguage for talking about science and for understanding the nature of their own discipline*" (p. 1015). Therein, "these" are the detailed elements of Toulmin's pattern, as opposed to the composite, and thus simplified, terms "ideas" (claims) and "evidence" (data, warrants etc., see below). Hence, TAP allows for the instruction of argumentation in a way that explicates the rhetorical elements of an argument as it is commonly used in natural settings (Driver et al., 2000; Toulmin, 2003). The essential parts of an argument according to Toulmin's pattern are

Claim – the assertion put forth

Data – facts given in support of the claim

Warrants – provide the connection between data and claim

Backings – commonly agreed upon assumptions in support of the warrant

Qualifiers – special conditions under which the claim holds true

Rebuttals – statements that contradict either of the other elements

These elements may be drawn out in the shape of a visually clear and distinct flow chart-like manner (see below). Note that such a pattern does only offer analysis of *validity or coherence of arguments*. Questions about "correctness" or "truth" must hence be evaluated otherwise, such as whether the data put forward supporting the claim are true or not, or to what degree an expert opinion is credible or trustworthy. Also, each of the elements of a given TAP might be considered a claim in itself, and consequently one TAP might induce one or more new arguments. These facts bear direct relevance to the work herein, and will be discussed below.

"KITCHEN STORIES" - ASSERTIONS ABOUT FOOD AND COOKING

In the world of food and cooking, assertions about what to do, how to do it, and occasionally why to do so, are abundant, be it in first rate restaurants or in the everyday cooking at home. Within the branch of food science called Molecular gastronomy (e.g. Barham et al.; This, 2002; This, 2009; van der Linden, McClements, & Ubbink, 2007), also termed "science-based cooking" (Vega & Ubbink, 2008) or "evidence-based cooking" (Enserink, 2006), such assertions have gained attention as objects of study. By some, they have been termed "culinary precisions" and are collected for the sake of historic, cultural and culinary knowledge building, and for analysis of whether they are true or not (This, 2002, 2005, 2006). For educational purposes I suggest that "kitchen stories" might be a functional and sufficiently neutral term and will be used herein (the rather common term "kitchen myths" is avoided as it carries unwanted connotations, amongst them that myths are often not true). Kitchen stories are at the present being collected by the thousands in several countries, foremost in France (This, 2008), examples being "*mushrooms should not be washed, but only lightly brushed*" and "*sprinkle lemon juice on sliced apples or pears to avoid the fruit turning brown*". It has been suggested that kitchen stories might be categorised according to what might be termed "expected likelihood": 1) some stories seem wrong and they are wrong; 2) some seem wrong and they are true; 3) some seem true and they are wrong; 4) and some seem true and they are true, and finally 5) uncertain stories which fall outside the first four categories (see This (2005) for examples). However, I contend that these categories lack precision and are rather difficult to apply in a scientific framework, and there is therefore room for some alternative rationale for categorisation and analysis of these stories. From the viewpoint of argumentation theory, bearing in mind Toulmin's argumentation pattern, kitchen stories might be considered to be *claims*. Being product of tradition, tacit knowledge, everyday development and handing down from one person to another, only occasionally such claims carry justifications explaining why the advice should be followed. Even more seldom are the claims backed by empirical data, and consequently TAP might provide a heuristic for detailed exploration of kitchen stories. When dealing with such stories, several of the argumentative components might not be stated explicitly, or be missing altogether. Through the process of "building a TAP" from a given kitchen story, a clear picture of the argumentative strength of each assertion emerges. One example of such an analysis is given in Figure 1.

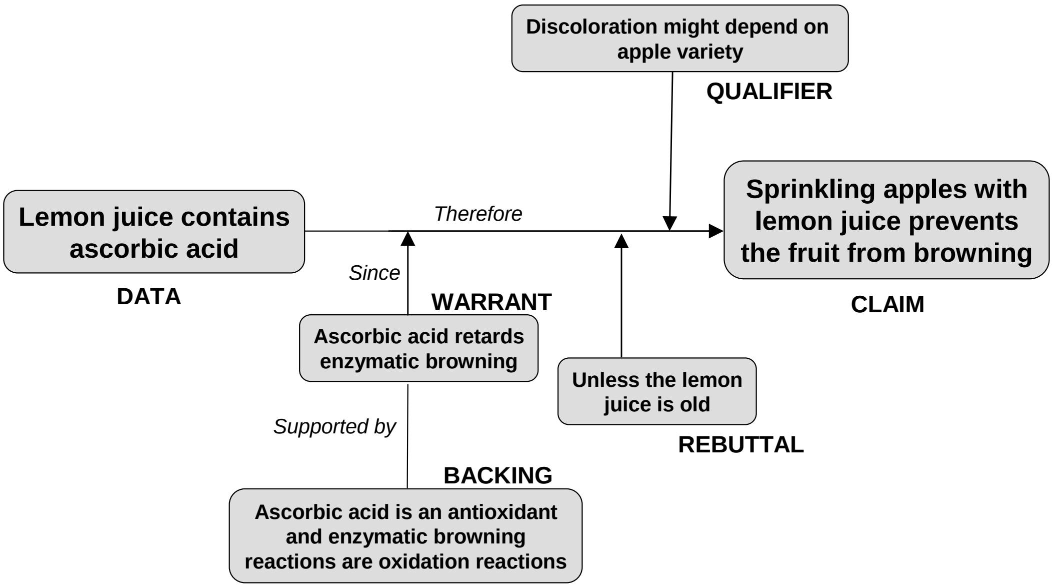

Figure 1. Example of TAP applied on a kitchen story about enzymatic browning processes. In this case, the TAP is completed, starting from only the claim, using inference and scientific content knowledge. Note that it is commonly possible to build more than one TAP from a given claim. The one shown here offers one example among several possible.

The project described herein seeks to integrate argumentation, in particular TAP, with kitchen stories to achieve a framework that can be utilised to promote understanding of concepts of evidence and argumentation, at the same time allowing for inquiry into authentic situations with relevance to everyday life.

PROMOTING ARGUMENTATION AND INQUIRY THROUGH ANALYSIS OF KITCHEN STORIES

Assertions concerning food and cooking, like the ones mentioned above, are firmly rooted in tradition and everyday life, and are familiar to most pupils, students, teachers and the general public alike. Due to the vast number of kitchen stories, this brings about a virtually inexhaustible source of potential inquiry projects. Also, kitchen stories are readily available for almost everyone to collect, given a cookbook, searching the internet, or interviewing primary sources such as family members, artisans or chefs. To my knowledge, the precedence for teaching argumentation, and TAP, is dominated by discussion of predefined questions, concerning either scientific or socio-scientific issues (e.g. Jimenez-Aleixandre et al., 2000; Kelly & Takao, 2002; Kolstø, 2006; von Aufschnaiter, Erduran, Osborne, & Simon, 2008; Zohar & Nemet, 2002). Kitchen stories afford an approach in which questions span between open-ended and fully guided. This might depend on various matters, such as whether the phenomenon in question is known to the teacher in prior, whether it is the teacher that chooses a predefined kitchen story or the pupils are given the task to go hunting for kitchen stories to explore and so forth.

The focus of the project described herein has hitherto been to involve pre-service teacher students in order to promote understanding of evidence and argumentation through the explicit instruction and use of TAP. 20-30 Norwegian students in food & health (a school subject closely related to home economics) and science classes attended a teaching sequence consisting of two units of each three weeks dealing with kitchen stories, argumentation and inquiry. The students were of mixed educational backgrounds and were at different points in the progress of their teacher education. They were organised in groups of 3-4 participants and group composition was as far as possible sought maintained throughout both units.

TEACHING PROGRAMME AND PRELIMINARY RESULTS

At the outset, the contents of the first unit were predetermined whereas the contents and focus of the second unit was left partially open. This way, it was possible to incorporate and utilise results and experiences acquired underway in the further development of the programme. The assignment was not subject to final examination, but formative assessment was given throughout the process in order to support the groups' progress.

FIRST UNIT – BUILDING VALID ARGUMENTS FROM KITCHEN STORIES

The unit was initiated by teaching sessions on argumentation in relation to the nature of science, citizenship and everyday life. The students were presented to TAP together with complementary teaching tools such as concept cartoons (Keogh & Naylor, 1999, 2000). They were allowed to practice the use of TAP on arguments and claims that had in prior been prepared by the lecturer, beginning with exercises on small, well defined problems, moving on to increasingly open-ended argumentative analyses. These preliminary tasks were done as group assignments with plenary summing up. This way, instruction was to model the use of TAP in a "controlled environment" so that all students should be able to reach a more or less definite conclusion on how to construct a complete TAP when starting from a claim. Following this teaching sequence, the groups were given a detailed prescription of which steps to take in order to solve the kitchen story assignment. It has been shown that careful structuring and modelling of the students' tasks is a prerequisite in order to support argumentation practice (Osborne et al., 2004a). Hence, a high level of detail was given in the assignment description, each step promoting skills in specific aspects of nature of science and argumentation. The students were asked to:

1. *Collect a number of kitchen stories from various authentic sources of their own choice (number equal to four stories per group member).*

   The sources emerging were various internet pages, cookbooks or personal communications (e.g. family members, friends or the students themselves)

2. *Among the collected stories select 3-4 which were to be scrutinised using TAP.*

   In this process, the groups had to make decisions about which assertions were more likely to end up as successful complete arguments as well as, at a later point, being verifiable in experimental inquiry (see below).

3. *Build a complete argumentation pattern including as many as possible, preferably all, the elements given by Toulmin.*

   The students were to expand from the claim resulting in a complete, albeit hypothetical, argument. A complete argument according to Toulmin's pattern might be valid, but still not "true" or "correct" in the sense that one or more of the elements might be faulty even though the argument itself holds. As a result, it was necessary for the students at a later point to test or challenge the various elements, and possibly revise the TAP according to scientific content knowledge or empirically derived information.

4. *Give some initial suggestions to how the kitchen stories under study might be tested experimentally.*

This part was given in order to prepare the students for the second phase in which some of the stories were to be tested empirically (i.e. in the case of sprinkling lemon juice on apples the students might suggest a comparison experiment subjecting apple slices to various conditions, such as vinegar, water, air, aqueous solution of pure ascorbic acid etc.).

5. *The results were to be documented as a written report containing information from all steps of the process.*

   Emphasis was given on students being able to justify choices and explicating their reasoning during the analyses. Furthermore, an extensive written response was given in order for the students to correct and refine their own work, since this was to be used as basis for phase two (described below).

The information at hand collected from this teaching process is not of sufficient quality to allow for a rigorous analysis of student responses and learning outcomes. However, some preliminary implications might be noted. Firstly, the students report that application of TAP on such authentic questions is a demanding task, but some groups were still able to successfully construct complete TAPs along with sensible suggestions to setups for experimental investigation. For a number of groups supervision was required in order to reach a complete and coherent TAP, and through this misconceptions concerning TAP or its elements could be identified. Examples of kitchen stories from the student assignments are (author's translations)

- *"Kiwis contain a compound that can dissolve jelly and is therefore not suitable in cakes and desserts that contain jelly"*
- *"Sprinkle the cutting board with water when cutting onions and you will avoid tears"*
- *"If you keep lettuce leaves in a bowl of cold water with ice cubes until the ice has melted the lettuce will become crisp and delicate"*
- *"Cooking carrots: the finer you chop the carrots before cooking, the more vitamin C will be lost"*
- *"For an extra light omelette, salt should be added after beating the eggs (rather than before)"*
- *"Bread and cakes stay fresh longer if you put an apple in the bread- or cake box"*

Secondly, in many of these analyses all the elements of TAP seemed to appear naturally as part of the process. This includes even rebuttals and qualifiers, the presence of which are often considered to represent argumentation at a higher and more demanding level (Erduran et al., 2004). One example of a TAP completed by the students is shown in Figure 2. From the figure it is worth noting how argumentation and science content knowledge are naturally integrated.

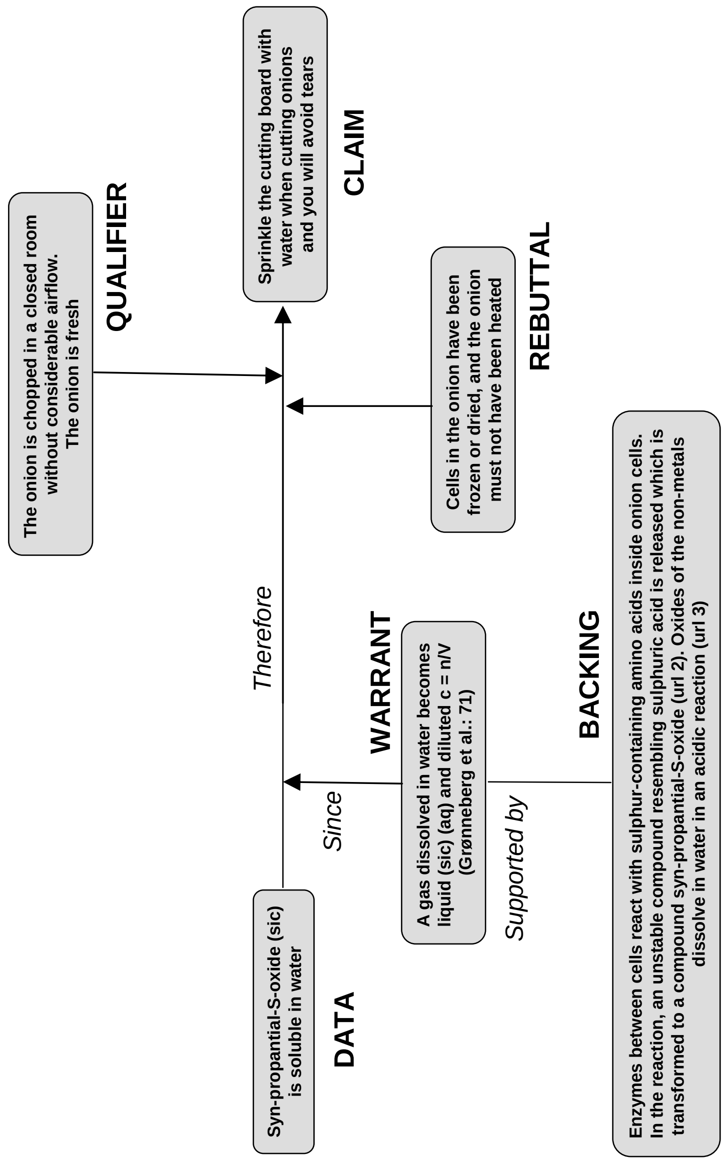

Figure 2. TAP constructed by students, starting from a kitchen story (claim). Author's translation.

Thirdly, in most cases it was necessary for the students to use appeal to authority-strategies (appeal to expert opinion) in order to complete the TAP and justify their scientific explanations (Walton, 2005). In doing this, a majority of the groups met problems in dealing with the epistemic status of various information sources. Examples include the use of commercial actors as sources for information:

"*[…] this is a source that has interest in being trustworthy*" (author's translation, students describing the web site of the Norwegian Egg Information Service)

"*It seems reasonable to believe that Coop has a certain justification for the assertions they publish on their web site since it is a trustworthy grocery chain*" (author's translation, students describing information from an "old wives' tales" page on the web site of the Coop supermarket chain)

Also, authority due to experience or craftsmanship emerged, such as

"*Assertion no. 7 is found in "The single person's cookbooks for absolute beginners". It is to assume that the authors of this book have good knowledge about cooking*" (author's translation)

This does not relate directly to the use of TAP, but rather to questions about truth or correctness (i.e. epistemological matters). A possible interpretation might be that the students hold domain specific, and contrasting, notions about source credibility between science and everyday life, as represented by the kitchen. The present information does not allow for drawing any conclusion on these matters, however, but represents an interesting lead to follow in future studies.

Hence, the main inferences that might drawn from this first part of the study is that, with varying degrees of scaffolding through supervision, (a) the students were able to build complete TAPs from a claim; (b) the students were able to give reasonable suggestions for experimental setups in order to investigate the claims (not described in detail herein); and (c) there was need for an increased emphasis on source evaluation. As a result, the following unit was designed so that the students had to explicitly discuss and justify their evaluation of the various information sources.

SECOND UNIT – EVALUATION OF SOURCE CREDIBILITY AND EXPERIMENTAL TESTING

This part was carried out the following semester, and the students were to build upon their first report as well as the detailed written response from the lecturer. This assignment was structured in a similar manner as the first phase, and the students were asked to:

1. *According to the lecturer's response, revise and re-evaluate the kitchen stories and TAPs from the first phase.*
2. *Carry out a critical evaluation of the various information sources and references used in the analysis, especially those used for justification purposes.*
3. *Make a justified choice of one or two among the analysed stories for experimental testing. Make a detailed plan for this testing based on a simplified version of the hypothetico-deductive method.*
4. *Carry out the experiment as planned.*
5. *Document the results in the shape of one experiment report for each kitchen story based on the IMRaD research paper format (Introduction | Methods and materials | Results | and | Discussion). Each report was to contain both the revised argumentation analysis of the story as well as a detailed source evaluation and an experimental account. In addition, one document was to be submitted containing the group's reflections concerning choices made, the work process and so forth.*

As part of the source evaluation, it is worth noting that there is a distinction between information sources used for kitchen stories (claim) and sources of factual information that are sought to fill the function of the other TAP elements. In the former, no emphasis is given to the trustworthiness or credibility of the source, whereas the epistemic status of the latter (data, warrant, backing, qualifier and rebuttal) is imperative.

DISCUSSION AND PROSPECTS

The framework described above consists of several elements, all of which are relevant to a nature of science-perspective in education. First and foremost, it is shown that kitchen stories provide for an entry point to teach argumentation. The topics covered by kitchen stories draw on both socio-scientific and subject-content matter and might provide a bridge between these two, rather than leaving one to choose between one or another which often seems to be the case (Osborne et al., 2004a). An explicit approach to teaching argumentation is achieved as students are forced to formulate the various TAP elements themselves in the process of building a valid argument. Furthermore, kitchen stories clearly invite the students to utilise all the elements in Toulmin's pattern; rebuttals and qualifiers emerge as natural elements when the claim is challenged. As an integral part, students need to evaluate the credibility and trustworthiness of various information sources, subsequently leading to the planning and carrying out of experiments.

Zohar and Nemet (2002) refer to previous research giving important factors in the explicit instruction of argumentation. These are shown to be a) knowledge about the structure and nomenclature of arguments and about the characteristics of a good argument; b) writing for enhancement of argumentation skills; c) teaching metacognitive knowledge about argumentation; and d) using authentic problems. The framework described herein will answer to at least three among these four characteristics, allowing for the application of TAP in a meaningful manner on authentic situations; a science teaching in which scientific enquiry is not only imitated by introduction of hypothetical problems but driven by real-life questions. Furthermore, von Aufschnaiter et al. (2008) reported that prior content knowledge, or experience, is *a prerequisite for* rather than a product of quality argumentation among pupils. Since kitchen stories might represent situations somewhere in between socio-scientific issues and scientific content knowledge they might provide opportunities for bridging the gap between scientific content knowledge and everyday issues (e.g. one needs to have a certain understanding of chemical reactions to be able to explain why the ascorbic acid in lemon juice prevents the apples from turning brown). This affords interesting possibilities for future research into the continuing study of the interrelationship between argumentation and scientific content knowledge. Subsequent to the argumentative exploration, experimental inquiry is introduced as a natural continuation. Lawson (2003) proposes that synergy effects might arise when inquiry (in shape of hypothetico-predictive argumentation concerning scientific concepts) and argumentation are linked. It might be contended that this is indeed the case when students study kitchen stories from the perspectives of argumentation and further plan and carry out experiments on order to test one's hypotheses concerning culinary claims.

However, school teachers might argue that involving pupils in collecting kitchen stories might pose a somewhat "risky business", since one cannot foresee the outcome and content knowledge covered by such a project. In such cases, the framework might include a few "ready-made" inquiry topics in order to model/scaffold how such a project might be accomplished, such as ascorbic acid in enzymatic browning, why one cannot make jelly with fresh kiwi or pineapple (degradation of gelatine by proteases from the fruit) and how this can be remedied, and so forth.

Future work within this project will aim at a more rigorous data collection in the use of kitchen stories for teacher education as well as exploring the potential for using this framework for other groups of students such as lower and upper secondary school, and possibly even primary school pupils. Indeed, Garcia-Mila and Andersen (2008) refer that children are shown to be able to justify claims as early as five years of age. Hence, the potential for kitchen stories as framework for such education purposes spans across almost every level of education, from lower primary school to university education. Even though food and cooking is a universal and essential aspect of life wherever humans exist, there should be cultural implications that need be addressed in order for the kitchen story framework to be applicable to education in diverse cultural contexts. Thus far, Scandinavian students have been the primary target, but it would be of great interest to expand this perspective to include a culturally more diverse range of students and pupils.

Finally, the field of argumentation (i.e. the use of TAP) might afford contributions of use even for molecular gastronomy as emerging scientific discipline, at least in the case of "culinary precisions" (kitchen stories) in which examples are emerging in the research literature (e.g. Dawson, Han, Cox, Black, & Simmons, 2007; Oruna-Concha, Methven, Blumenthal, Young, & Mottram, 2007; This, Meric, & Cazor, 2004). Hence, an intriguing perspective would arise if argumentation through science education could contribute towards knowledge building within the pure science, for once turning the perspective the opposite way around.

ABSTRACT

Studies on the teachers' conceptions of teaching and learning are not recent. The related results have been used, among other purposes, to help teacher education, itself. In Brazil, some studies on the teachers' conception of Distance Education (DE) have already been conducted, although they lack detailed information. This research, which is part of a larger research project conducted in several regions of Brazil, has the objective of investigating science teachers' conceptions of DE, both in the initial and continuing teacher's education. A case study was performed, in which questionnaires and interviews were used to collect data from 33 teachers in 18 towns of the State of Paraná. The results revealed that the teachers' conceptions varied from a range of negative characteristics to others connected with the need for DE. Four different groups of conceptions were identified: Distance Education as a Deceitful perspective, as a Useful resource, as a Possibility and as a Need. Regarding the initial teacher's education at distance, the rejection rate is higher than in relation to its application to the teacher's continuing education. The data presented herein may be used in teachers' education programs to make the teachers reflect and reconstruct their conceptions based on concrete information on the DE possibilities.

Keywords: *Distance Education, Teachers' conception, Science teachers.*

1. INTRODUCTION

Studies on the teachers' conceptions of teaching processes started in the early 70s, when many movements were initiated aiming to implement educational reforms.

Some authors described these conceptions as mental structures involving beliefs, concepts, meanings, mental images, etc., (Thompson, 1992), or as cognitive systems of beliefs and knowledge (Anderson, 1989).

The concept of science teaching, for example, was used by Hewson and Hewson (1989) to describe the teachers' ideas and interpretations used to take decisions about to the curricula.

The conceptions related to teachers' education have already been considerably investigated and studied (Roth, 1992) and according to Anderson (1989) the conceptions act as personal theories, which drive, among other things, the pedagogical practices of teachers. The author also says that teachers are responsible for rebuilding their own conceptions of teaching and learning through the course of their professional development.

In Brazil, the teachers' conceptions of DE have also been focused by recent studies. Recently, Garcia (2010) investigated the conceptions of a group of science teachers in a continuing education course at distance and Almeida (2007) analyzed a group of students (future teachers) in a Biology course investigating their interpretations of distance education. Both studies presented similar results, with a prevailing sense of mistrust and disbelief of DE with respect to course quality and the level of learning.

Also, Brazilian scholars have discredited the quality of distance education in Brazil, as witnessed by a fierce academic debate between those who do not accept the role of distance education in the initial education (Minto, 2009; Fétizon & Minto, 2007) and those who plead in favor of it (Litto, 2009; Sanchez, 2007; Cunha, 2006; Schlünzen, 2009).

The Ministry of Education (MEC), aware of this debate, has been implementing programs and projects of initial and continuing distance education. Public and private universities, education institutions, as well as certain groups linked to private education have launched programs and distance courses.

The DE expansion in Brazil reinforces the importance of studies on the teachers' conceptions of this modality of teaching. The resulting knowledge may be used in teachers' courses, even in those offered by MEC, providing the teachers with actual information on the possibilities of having quality distance education (recent national and international experiences, projects, quality programs), upon which they will be able to reconstruct their conceptions and enlarge their possibilities of professional development.

This study, which is part of a larger research study conducted in several regions of Brazil, has the objective of investigating in-depth science teachers' conceptions of distance education, both in the initial and continuing teacher's education, since these conceptions act as guidelines for decision-making in relation to their professional development.

BRAZILIAN EDUCATIONAL CONTEXT

In Brazil, the Ministry of Education is the body responsible for organizing and integrating the national education system of education. MEC, through its Secretariats, coordinates the policy guidelines for the organization, evaluation and teachers' education for both schooling levels, Basic Education (0-6 year-old; 7-14 year-old; 15-18 years-old) and Higher Education (Universities and Superior Education Institutes). However, the states and municipalities also establish guidelines and instructions for their specific education systems based on MEC policies.

In the last issue of the National Law of Guidelines and Foundations for Education (LDBEN/96), distance education was considered a modality of teaching that can be used in all national territories (Brasil, 1996). This law was ruled by some decrees: n.º 2.494, n.º 2.561 and n.º 5.622 (Brasil, 1998, 2005). These decrees detailed principally DE in terms of its working.

In Brazil there currently exists 257 Institutes of Education, including universities, authorized to offer courses in higher education, with 1181 courses in various areas and in different levels of education (Sanchez, 2008). In higher education, from 2004 to 2007 over 400 courses have been added. In terms of students' enrollment in these courses, there were 59.611 in 2004, and in 2007 it was almost 369766 (Mec/Inep, 2007).

The MEC is promoting some public policies to increase the equitable access to higher education Institutions by teachers. In order to do this, it created the Secretaria de Educação a Distância (Seed), the UniRede (network of public university system), the Universidade Aberta do Brasil (Open University), and some other projects to promote teachers' education, such as: Proformação and the Pró-Licenciatura.

Distance education has been an alternative well used by MEC to teachers' education in general, and to science teachers' education in particular. MEC insists that distance education could be a method for improving access to higher education.

DISTANCE EDUCATION AND TEACHERS' CONCEPTIONS

The teachers' ideas and conceptions in general and those linked to teaching and learning in particular, influence and guide their decisions on the pedagogical practices they elect (Anderson, 1989), and, we may also say, their professional development, since the learning act is deeply affected by preexisting knowledge and beliefs.

Teachers' conceptions may be seen, in a broader sense, as mental structures, which involve beliefs, preferences, concepts, propositions, rules, meanings, knowledge and mental images, among other things (Thompson, 1992). According to Anderson (1989) conceptions are cognitive systems of beliefs and interconnected knowledge that influence perceptions and reasoning.

Therefore, studies of the teachers' conceptions relate to the understanding of their values, motivations, thoughts, prejudices, knowledge, etc., which affect their pedagogical practices and their motivation to learn through DE.

Teachers' conceptions are affected (though not only) by: a) the social context (the conception of education, teacher's position in the society), b) the educational context (teaching theories, personal perceptions on students, parents, principals, methodologies, evaluations, education level), c) the political context (laws, curriculum, educational system values). The teachers' education, initial and continuing, as well as their political and ideological positions, also acts on their conceptions.

In the decade of 1970, studies started to approach the teachers' conceptions of education. In the field of science teaching, for example, Hewson and Hewson (1989) used the science teaching conception to represent the ideas and interpretations teachers used when making decisions related to the curricula.

Studies on these conceptions became more and more important for teacher's education (Roth, 1992), since, according to Anderson (1989), the conceptions work as personal theories which guide the pedagogical practice.

Recent studies in Brazil have attempted to understand the teachers' conceptions of DE. Garcia (2010), analyzing a group of science teachers' who attended a course of continuing education at distance, revealed that many of the professionals at the beginning of the course displayed negative feelings and mistrust towards this type of course; however, as they became familiarized with the DE processes, the negative ideas were replaced by more positive feelings.

In a research intended to analyze the conceptions of future Biology teachers in relation to distance education, Almeida (2007) said that the concerns of most students relate to the validity of the courses, the view of the job market on these professionals and the level of learning. The author also said that even those students, who recognized the DE courses capacity of narrowing borders, did not unreservedly trust this modality of teaching.

Many of the participants in this research said that they would not enroll in a Biology course at distance, due to the lack of practical and laboratory classes, which they understand as essential. However, when the process was explained, many of these students changed their position. This shows that the knowledge of the distance education processes may interfere on the teachers' view of this modality of teaching.

Although these studies have revealed a certain mistrust of teachers in relation to DE, they also showed that the most of the prejudice against these courses is based on the lack of knowledge and familiarity with the methodologies used in distance education.

Such discredit is also shared by many researchers, who do not rely on the quality of distance education courses. With respect of the teachers' initial education, opinions are polarized in two groups. On one hand, those who do not accept the inclusion of distance courses in the initial education pointing out their negative characteristics, superficiality, fragmentation of the teaching process and precariousness of teachers' work (Minto, 2009). Others, in favor of attendance courses, criticize the inadequacy of the legislation regarding DE and do not agree with its use as a public policy of teachers' education (Fétizon & Minto, 2007). On the other hand, there are researchers who understand that distance education offers great contribution, compensating for the lack of universities in Brazil and helping many students with special needs (14% in Brazil). Others recognize the importance of distance education courses in the democratization of the access to higher education (Sanchez, 2007) and to supply the lack of qualified teachers (Cunha, 2006; Schlünzen, 2009).

The Ministry of Education, aware of the debate about the general sense of mistrust regarding distance education, continues to expand its policies related to the teachers' initial and continuing education, attempting to facilitate the access to higher education. Public and private universities, as well as private groups and even schools are already launching distance education programs and courses. Within this expansion of DE courses, studies on the teachers' conceptions gain importance, either to demystify or to improve this teaching system.

2. METHODOLOGY

This study is part of a larger research project conducted in several regions of Brazil. The overarching research question being addressed is: What are science teachers' conceptions of distance education in Brazil, both in the initial and continuing teacher's education?

In order to investigate science teachers' conception of distance education two study cases were carried out in two regions of Brazil. One of the regions "Grande ABC Paulista" includes 6 towns (southwest), a major industrial and business area in São Paulo metropolitan area. The other region includes 18 towns around Cascavel (state of Paraná), in the middle of a rich rural area in southern Brazil. Both areas present leading indicators both social and economic. In this study, we present the data from the southern of Brazil.

This sample of participants was obtained where the researcher had access to schools, and where science teachers were, effectively, being affected by distance education courses. The sample has, at least, one participant of all 18 towns, and these science teachers were chosen randomly from 54 high schools.

In this region are nearly 300 science teachers working in these Elementary and Secondary schools; both quantitative and qualitative data was collected from 33 teachers participating in the study.

Data from the quantitative methods using a Likert Scale, has not been completely analyzed. In this study, we present only the data from qualitative data collection methods.

Qualitative research interprets information in a broad way, within the context where the research subject is located, involving the collection of predominantly descriptive data, and highlighting the process more than the product and showing the investigational subjects' perspective rather than the researchers'. (Ludke & André, 1986).

The line of qualitative research is bound to the interpretation of environments, considering that every environment, the place where people live and interact, is surrounded of meanings and senses. It is through such interactions that people build up their realities, through experiences that are highly valued by the qualitative focus.

According to Ponte (1992) studies on teachers' conceptions clearly have limitations related to the methodologies used, since many teachers do not feel comfortable to participate in this type of research. He suggests the use of interviews rather than direct questions, observations and document analysis. All these data must be crossed carefully in order to find out the conceptions. This study used a combination of two research techniques: interviews and questionnaires.

An interview with a pre-defined script was conducted with 10 teachers and questionnaires were answered by other 23 teachers. More interviews were discontinued because saturation of the date made further collection unnecessary. Freire Junior (2005) cites that saturation occurs when the researcher, after a certain number of interviews, realizes that the data explain the object of research on their similarities and differences. Thus, data from interviews do not bring newer information to that already acquired.

The interview was composed of questions about participant profile (gender, age, marital status, level of education, working hours per week, experiences with technologies and distance education), and about teachers' conceptions regarding the DE: how they understand DE, what is the level of Brazilian education they consider DE more appropriated; how they see DE contribution to science teachers' education, and how they distinguish the relationship between DE and conventional education.

The data obtained in the interviews served as the basis for constructing the questionnaire.

The questionnaires consisted of questions on the participant profile: gender, age, marital status, level of education, etc.. The open-ended questions in the survey related to the teachers' conceptions of DE, distributed into 4 categories: 1) understanding DE; 2) DE suitability; 3) contribution of DE to science teachers' education, and; 4) relationship between DE and conventional education.

The first category describes the teachers' conceptions of distance education. The second explains in which level of education in Brazil DE is considered to be more appropriate. The third focuses on how the teachers view the contribution of DE to education, and the fourth portrays the relationship between distance and conventional education.

3. FINDINGS

The results are presented and discussed according to the categories previously defined.

Positioning Distance Education.

The teachers' participants placed distance education within a spectrum that goes from negative characteristics to features associated with the need for this kind of courses. Four groups were identified, based on their conceptions of DE:

1) Teachers who associate DE with a "Deceitful" perspective;
2) Teachers who see DE as "Useful";
3) Teachers who link their conception of DE to a "Possibility of access"; and
4) Teachers who place DE as a "Need".

Teachers of the first group, who see DE as deceitful (12,1%) said that these courses provide a certificate without accomplishment of learning, a weak form of learning when compared to attendance courses and the illusory idea that DE compensates for the lack of schools.

Teachers who related DE to usefulness (36,4%) see this type of courses as useful for the teachers' continuing education, since they can be used to deepen the knowledge already acquired and may be advantageous when taken with seriousness and dedication. However, these teachers also said that distance education cannot replace conventional education and is unsuitable for initial education when the student is not yet able to study by himself.

1.1.1. Those who associated the conception of DE to the possibility of access (42,4%) said that these courses may be a solution for students who do not have time or conditions to physically go to school or universities. They also said that many people may benefit from DE and have their work possibilities enlarged, but only when the courses are seriously faced. In their opinion, education at distance does not replace conventional attendance courses and should not be used to provide graduation certificates, because students at this level lack the required maturity.

1.1.2. At last, the fourth group of students related DE to a need (9,1%) due to the high demand for knowledge (schools or universities do not meet this demand) and the needs of those who could not attend conventional courses. They understand DE as an essential modality since it reaches worldwide levels.

1.1.3. Even the teachers who approve distance education, either as a useful resource, a possibility of access or a need, agree that this form of education does not replace conventional courses, it is not suitable for initial education and ought to be treated with seriousness.

Suitability of Distance education

Regarding the suitability level of distance education, the teachers' participants said that: a) it is suitable for continuing, but not for initial education; b) it depends on the course and the institution; c) it is not suitable for initial, neither for continuing education; and d) it is suitable for both stages of teachers' education.

Of these teachers, 69,7% said that distance education is suitable for continuing, but not for initial education, based on the following justifications: a) nothing replaces attendance classes, mainly when it comes to didactic and methodological subjects, or laboratory classes; b) distance education does not supply the students' initial needs; c) initial education requires previous knowledge; d) subjects of teachers' initial education are complex; e) the teacher needs a solid pedagogical basis; f) exchange of knowledge/experiences is critical for a satisfactory learning level; g) commencements are usually turbulent; and h) personal contact with a teacher is important for the learning process. On the other hand, in relation to the continuing education, these teachers commented that: a) distance education may be seen as another option; b) it supplements good professionals' natural search, as long as these professionals have attended traditional initial education, and c) distance courses must be constantly evaluated.

Another group of teachers (6,1%) said that the suitability of distance education courses depends mainly on the institution and on the resources used.

Also, in the opinion of 18,2% of the teachers, DE is not suitable for initial and neither for continuing education because of the lonely conditions to study and solve problems, lack of intermediation of a teacher and lack of interaction. They also point out the difficulty to form good teachers even at attendance courses and the importance of a supportive teacher for the students. One of the participants commented how unacceptable it would be a distance education course to form surgeons.

At last, 6% of the teachers agreed with the idea of DE for initial and continuing education as well, since it would help many people who could not initiate their major courses.

Contribution of distance education to the teachers' development
With respect to the contribution of distance education to the teachers' development, particularly science teachers, the respondents were classified into three groups: a) yes, DE does contribute to the teachers' education; b) DE provides little contribution; and c) it depends.

Most of the teachers (84,8%) said that distance education can contribute to their development by providing, for example, refreshing courses, in-depth supplementary courses, exchange of experiences with professionals from other regions, access to knowledge. Some teachers added that this contribution depends on the teacher's maturity, participation and dedication level, and that it is important to have attended a traditional initial education which ensures certain required knowledge.

For the other group (9,1%), distance education can provide little contribution to their development, since these courses do not fully meet the needs and still present some restrictions. A smaller number of teachers (6,1%) said that the contribution depends on the seriousness of the course and the teacher's participation.

Relationship between attendance and distance courses in the teachers' education
Almost the whole group (84,8%) think that the existence of distance education courses does not represent a threat to attendance courses. For 15,2% of the teachers, conventional attendance courses will be someday replaced by distance education courses.

4. ANALYSIS AND IMPLICATIONS

The data obtained presents the science teachers' conceptions of distance education and aspects related to the contribution of this modality to the initial and continuing teachers' education.

The conceptions varied from negative characteristics to the need for distance education. Four broad groups of conceptions were identified: DE as a deceitful resource, as useful, as a possibility of access and as a need.

It is worth mentioning that even for those teachers who associated DE with usefulness, possibility of access or need, education at distance does not replace traditional education, and ought to be seriously treated.

Furthermore, teachers said that DE is indicated as a possibility for those that do not have time to attend traditional school (or college), or as a way to provide access for those that are away from the universities.

Teachers also said that DE is necessary for those that could not study in traditional courses. It means that these professionals considered DE as a possibility of access or as a need for those that were excluded of traditional education.

Most of the teachers surveyed do not consider DE suitable at the initial education, but tend to be more receptive in relation to DE for continuing education. And here again, the seriousness of the courses offered was emphasized.

Teachers' conceptions are more in line with those of the researchers who are against distance education courses at the teachers' initial education (Fétizon & Minto, 2007; Minto, 2009).

Part of these conceptions, according to Gomes (2007) is based on the fact that distance education courses, in many regions of Brazil, are seen as second-class education or as a manner to regularize the situations of individuals who could not attend traditional education.

The prejudice against distance education arises, many times, from the apparent lack of effort to obtain the certificates, lack of commitment from students, insufficient learning, lack of seriousness in the courses offered, etc.. However, the prejudice is also supported by the lack of knowledge on the current possibilities offered by distance education, and its association with, for example, dressmaking or electronics technical courses and supplementary fundamental education courses, which were generally offered by mail in the past.

Another reason for the disbelief that surrounds the distance education courses is the fact that many of them are offered and monitored by the government, with questionable quality.

The present study enlarges the results found by Garcia (2010) and Almeida (2007) and provides a deeper understanding on the subject, which could be used in the continuing education programs for science teachers.

As from this understanding and based on recent national and international experiences, projects and programs, the teachers may be led to think over and reconstruct their conceptions. They can compare their conceptions with concrete information on the possibilities of having distance education with quality.

Besides, experiences may be organized in order to make the teachers more familiarized with this type of courses and change their conceptions, since distance education offers many possibilities of professional development.

Guedes, Mehlecke and Costa (2008) also suggest the need for more courses of continuing education through the use of new technologies, with the purpose of involving the professionals and making them more aware of the processes and benefits of distance education.

Ultimately, the teachers' conceptions presented in this study hinder the teachers' development, to the extent that they do not feel motivated by DE. Since learning is closely linked to motivation, their conceptions end up adversely affecting their professional development.

The new data analysis, we will perform in the following months from southwest of Brazil, will allow us to better understand science teachers' conceptions of distance education. However, considering the results presented here, we can say that there are at least five direct implications related to the Brazil' Ministry of Education. As from these data the MEC can launch a national program, as part of public policies to: 1) demystify DE to teachers, 2) inform and aware teachers about the possibilities and benefits of distance education, 3) improve DE processes and methods, 4) improve the monitoring processes of distance education courses, 5) initiate projects to better familiarize teachers to DE processes.

ABSTRACT

In this study 18 to 19 years old upper secondary students' ability to discern the use of multiple models in genetics when reading content specific excerpts in Biology textbooks are investigated. Two excerpts using different models when describing gene function was selected from authentic textbooks and nine students were given the specific task of reading the excerpts. Afterwards the students participated in semi-structured interviews. The main theme of the interview was about how the students experienced the similarities and differences between the texts, and how they understood models and conceptual change in genetics. Students recognized the existence of multiple models in a general way, but had difficulties discerning the different models and the conceptual change that occurs between them in the texts. Students had difficulties in transforming their general knowledge about multiple models into understanding of content specific models of gene function in the textbooks. These findings may have implications for students' understanding of conceptual knowledge since research has established textbooks as one of the most influential aspects in the planning and execution of biology lessons.

Keywords: *Genetics, Models, Students' understanding, Textbooks*

BACKGROUND

Models and their importance in teaching science have been the object for extensive research in science education during last decades (Gilbert & Boulter, 2000; Grosslight, Unger, Jay & Smith 1991; Halloun 2004). In teaching genetics the use of models and modelling has been emphasized as an important aspect in improving students' conceptual understanding (Finkel & Stewart, 1994; Thomson & Stewart, 2003). The use of models is also regarded as a vital component in many steering documents. The national Swedish curricula for the science program (grade 10-12) in upper secondary school states that: 'Thinking in terms of models is central to all the natural sciences' (The Swedish National Agency for Education, 2009, p. 35). Similar claims can be made on the basis of the American Association for the Advancement of Science guidelines (1990, 1993). The benchmarks from AAAS (1993) state for students in grades 9 through 12: 'The main goal should be getting students to learn how to create and use models in many different contexts' (p. 270).

Models play a central role in the outcomes of science (Giere, 1988). There is no unique definition to the term *model* in the literature, and there is no consensus of the use of the term, be it philosophers of science or science educators (Halloun, 2004). In this paper, a model in science is seen as a representation of a phenomenon initially produced for a specific purpose. The model is a simplification of the phenomenon intended to be used to develop further explanations of the phenomenon. Moreover models also play an important role in communicating science. Through comparison and testing, a model may reach agreement among scientists and become what is called a scientific model (Gilbert, Boulter & Rutherford, 1998). The development of different scientific models over time, representing the same phenomenon, has led to the occurrence of so called multiple models, see Figure 1. In school multiple models are often used implicitly to describe a specific phenomenon. For example the billiard ball model, Bohrs' planetary model and the electron cloud model are all used to represent the atom in upper secondary school.

The problem of fitting different gene concepts together is well known from the philosophy of genetics (Beurton, Falk, & Rheinberger, 2000; Gerstein et al., 2007; Portin 1994), which has led to the development of different explanatory models depending on: which aspects of the genetics that were studied; which technological devices were at hand; which model organisms that were used etc. Therefore the historically developed concepts in genetics belong to different scientific frameworks although the same term might be used. In a previous study (Gericke and Hagberg, 2009) it was found that multiple models were used as representations of gene function in school textbooks. Moreover it was shown that these models were used in an explicit way without reference to the fact that the textbooks frequently shifted from one model to another. In this study we wanted to find out how the students interpret and understand this implicit use of representations in their own textbooks.

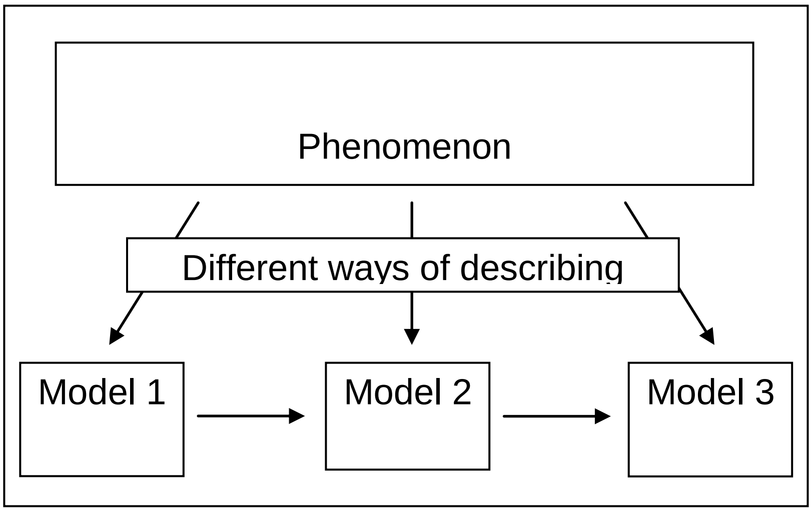

Figure 1. A phenomenon can be represented by multiple models.

Learning to use scientific models is challenging for students and is closely intertwined with the problem of conceptual change. Without conceptual change in how different models are understood, students will misunderstand and misuse the models they are learning (Chinn and Samarapungavan, 2008). It could be expected that students may have difficulties in understanding the conceptual knowledge where there is a variation in the description of the same phenomenon by using different models. In school textbooks the students themselves must discover the different multiple models found in them, since textbooks do not explicitly deal with the occurrence of models in science (Gericke and Drechsler 2006; Harrison, 2001).

In this study18 to19 years old students attending the science program (grade 11 and 12) at upper secondary school in Sweden were investigated. The students' ability to discern the variation and use of multiple models of gene function when reading content specific excerpts in biology textbooks is investigated.

The research questions that guided the study were:

- How do 18 to 19 years old upper secondary students in the domain of genetics understand the use of multiple models, and the conceptual change that occurs between models, in biology textbooks?

METHOD

Design

Nine students, all 18-19 years old and attending the science program (grade 11 and 12) in upper secondary school in Sweden participated in this interview study. Hence these students represent that cohort of students in Sweden that take the most advanced courses in biology and chemistry at the upper secondary school.

The students have actively chosen to participate in the study. According to their teachers the students represent an average of achievers of this cohort of students. In order to ensure that the students were average achievers they were sampled from a larger cohort by using a questionnaire instrument, which probed students understanding of models. Average students were asked to participate in the study. The students come from two schools in two different towns. Before volunteering they were given detailed information about the study. The students were first given the assignment to read two texts at home until a specific occasion when they were interviewed. The students were told to put in as much effort to their reading as they regularly do when getting homework/tasks in school. It would have been possible to use any of the available biology textbooks in Sweden, but these textbooks were choose since the schools participating in the study used these books in their biology courses.

The texts were in a previous study classified by the researcher as being representative to two different models describing gene function (Gericke and Hagberg, 2009). Text 1 represents a classical model and text 2 a neoclassical model. Here follows a description of the two texts:

Text 1: The headline for text 1 (Henriksson 2007a, pp. 40-51) is *Genes are inherited,* and the text describes Mendelian inheritance among plants and animals with classical examples from peas and fruit flies. A strong connection is drawn to the chromosome, but DNA is mentioned as the base for a gene. The text includes several genetic crosses with pictures visualizing a phenomenological level of how the genotype contributes to the phenotype. The text is situated in a framework of classical genetics and a historical reference is made to the scientist Hunt Morgan's fruit fly experiments. The text represents a **classical model** of gene function. In such a model the gene is viewed as a particle unit on the chromosome which defines a characteristic or a trait at a phenomenological level. The explanations in the model are causal and idealistic only describing relations. Explanations on a macro level are extrapolated to the cellular level and the gene is defined by a top down approach. The classical model is thoroughly outlined in Gericke and Hagberg (2007).

Text 2: The headline for text 2 (Henriksson 2007b, pp. 32-36) is *Nucleic acids*, and the text describes how DNA is built up, the genetic code, mRNA and protein synthesis. The description is at the molecular level but also at the cellular level. The text includes several illustrations of biochemical processes such as replication, translation and splicing. A short passage of the text refers to the historical findings of the structure of the DNA-molecule by Watson and Crick. The text represents a **neoclassical model** of gene function. In such a model the gene is defined as a stretch of DNA which defines the polypeptide or protein it produces. The explanations of the model are given on the molecular- or cellular level and try to describe as naturalistic as possible the biochemical processes that take place in this production. The model uses a bottom up perspective and gives a deterministic view of the gene. The neoclassical model is thoroughly outlined in Gericke and Hagberg (2007).

Interviews

A semi structured interview was designed according to Kvale (1996). An interview guide was constructed. The three main themes of the interview was about how the students:

- Experience the similarities and differences between the texts
- Understand models and conceptual change in genetics
- Understand models and conceptual change in general

All questions were asked in relation to how they appear in textbooks. The textbooks were on hand in the interviews and the excerpts were used as a starting point for various questions. A interview was conducted with each of the nine students, lasting about 45 minutes.

The interview consisted of three distinct phases: the briefing and warm-up phase at the beginning, the main phase, and the debriefing phase at the end. During the main phase the themes stated above were discussed. The main phase of the interviews was recorded and transcribed in full. After transcription the second researcher once again listened to the tapes and proof-read the transcripts.

Student transcripts were coded according to the students related to: differences/similarities between the texts; models and conceptual change in genetics, models and conceptual change in general. A matrix was constructed in which the coded answers were transferred and correlated to the different themes. In that way we could describe what was characteristic for the students' ideas about each theme. The development of the matrix was discussed between the researchers so that inter-coder agreement was obtained.

RESULTS

What are the differences between the texts?

Most of the students experienced the differences more than the similarities between the two texts' descriptions of the gene function. One of the students who thought the texts portrayed more or less the same model assigned the differences between the two texts to a matter of for example disposition or layout, i.e. non-content explanations (see category 1 in Figure 2). When characterizing what the differences in the description of gene function consisted of, usually a dichotomy between the two texts was mentioned (see Figure 2). Several of the students claimed that one text was more thorough and detailed in the description then the other (see category 2 in Figure 2). Two of the interviewees (S1 and S2) explicitly stated that the texts portrayed the same model. Differences between the texts were referred to the possibility to explain with various depths:

> S2 – Yes the texts have different depths of their descriptions. (Classified as category 2 in figure 2)

Otherwise comments were made about specific content dichotomies between the texts such as macro/micro level; traits/DNA; gene structure/ gene function etc. (see category 3-8 in Figure 2). Four students could reinforce their statement about the differences with several claims, but most often only a short explanation was given as exemplified of the following citation:

> S8 - I thought that this [text 1] described more how genes control the heritage, more what you will look like and so. This [text 2] described more how the genes work. (Classified as category 4 in Figure 2)

1. Non content explanations (e.g. disposition, layout, difficult to understand)
2. Explanations are more simple or easy / explanations are more complicated or detailed
3. Explanations on macro level / explanations on micro (cell- or molecular-) level
4. Explanations about heredity / explanations about how the gene works
5. Explanations about chromosomes / explanations about protein production
6. Explanations about traits / explanations about DNA
7. Explanations about gene structure / explanations about gene function
8. Explanations about the importance of the environment / explanations excluding the importance of the environment

Figure 2. Categories of student answers to what differ between the two texts.

To elucidate this question further we asked the students why they believed genetics was described in two separate chapters in two books instead of in a single chapter. The idea was to find out if the students could refer to the fact that the two texts depict two different scientific frameworks, classical genetics and molecular genetics. All the students in the interviews recognized that both texts were dealing with genetics. Five of the students (S4, S5, and S7-S9) gave similar content related reason, as stated in the question about the differences between the texts, to why the authors divided genetics into two chapters. For example S8 said:

> S8 - Perhaps it has to do with the fact that they [the texts] deal with very different things. The first [text 2] is about how genes function and the second [text 1] how the genes affect our appearance. These are actually quite different things.

The other students' answers to this question (S1, S2, S3 and S6) were non-content explanations such as layout- and disposition reasons.

> S6 - you understand more fully if it is structured properly. I would almost think it just as easily could be presented in one text.

Hence S3 and S6 gave different answers to these two questions indicating it being difficult for students realizing that the historical development and structure of scientific knowledge may be an important tool for structuring the content of textbooks.

The conceptual incoherence between the two texts

The conceptual change that occurs between the two models portrayed in the different texts leads to conceptual incoherence, and to find out if and how the students looked upon these contradictions between the texts they were asked accordingly. We did not use the term incoherence, instead we discussed whether the students could recognize any contradictions or conflicts between the content in the two texts. All the interviewed students except S7 did not recognize any contradictions or conflicts between the content in the two texts, which is remarkable since we in the interviews explicitly showed the students different descriptions in the texts. For example in a question about different descriptions of the gene in the texts S9 says the following:

> S9 - I do not think the descriptions contradict each other, they really say the same thing, and it depends on how you interpret. A bit of a DNA molecule ... DNA is the chromosome when it is folded, so really it is the same thing, just told with different words.

Student S7 was able to recognize that the structural description of the gene differed in the texts after some discussions:

> S7 – Yes, how these segments that create proteins works. It might not be just that part of the DNA, but it might be several pieces of the string of DNA that code for a certain protein. Then the gene would be scattered over several locations.

To clarify these important aspects regarding the use of multiple models the discussions in the interviews was broadened and the students were asked about their experiences about contradictions or conflicting descriptions of a phenomenon in their science textbooks in general, and the students were asked to exemplify. Six students claimed that they had never experienced such contradictions or conflicting descriptions.

> S 2 - No, I can not think of any books in which I come across such contradictions.

S4 said he often encountered such contradictions but he could not give an example. S8 claimed that her physics teacher had attracted her attention to contradictions within the phenomenon of acceleration, but she meant that biology was a more precise science in which there were no such contradictions. The only insightful example about a scientific stated contradiction was given by S7 about thermodynamics.

> S7 - It may well be… yes in physics with the conservation of energy and then later, it may be stated [in the textbook] that energy is created. It seems to me, it is so obvious erroneous, so you get disturbed about it.

After showing two contradictory examples in the texts the students were asked how they would react if they encountered two contradictory descriptions (models) of a phenomenon in a textbook, and how they would answer if studying before a test. One student (S5) could not answer and three students (S1, S2 and S8) said they would try to ask the teacher and let him decide what the correct answer is. Otherwise you have to ‘go after your ‘gut feeling’ and use the description you think is right’. These four students more or less regarded conceptual contradictions as flaws in the books.

> S2 - first if you discovered it [in the textbook] you would of course be a little confused by what was true and ask the teacher if he has time, but if it's the night before [a test] you maybe just pick one [way of answering].

S6 answered he would explain as detailed as possible in a test and S3 would show similarities and dissimilarities of the descriptions. Only two students had a more complex way to approach the problem. S7 claimed he would try to describe how the different contradictory aspects related to each other, and S4 interestingly said that he would try to find out in which context the questions are given and answer in a way that is most proper for that context.

> S4 - Yes, then you… if it has been described in different ways, you must try to see in what context the question is given to you in the test.

The use of multiple models in the texts

To be able to understand the use of multiple models it is important to understand science as a way of knowing, i.e. the nature of science (Lederman, 2007). Therefore some of the questions in the interviews revolved about these issues. The students were asked if there is an ultimate 'true' definition of what a gene really is, and whether this definition was presented in the textbook. Six (S1, S3-S6, and S9) of the interviewees believed there was an 'ultimate scientific definition' and three believed no such definition was available. Though the difference between how these two categories of students understood this problem was minor since most of them refer to different descriptions of the phenomenon as either different aspects, i.e. different scientific explanations are thought to capture different spatiotemporal views rather than different theoretical viewpoints, or as different levels of explaining.

> S8 - After all, it is both. The genes are part of the chromosome and they [the genes] also have a DNA, so in that way it is both.

This was also evident when the students in the interviews were shown the different multiple models of gene function visualized in concept maps:

> S4 - It is due to the first explanation is based on the second, in my opinion. The first one over there [points to a concept map of the classical model]; it may represent more of this first text [text 1], perhaps the second one, then goes more into depth.

Only two students understood this question as a part of the development of science as a human endeavour and had therefore the ability to problematize what is meat by a truth in science.

> S7 - Mm. It is perhaps by definition, any other… it may well, if there are different ways to define it [the gene] and maybe you do not agree on what the definition is.

Noteworthy in the interviews, almost no reference was made by the students of how scientific knowledge is acquired in science, i.e. aspects about the nature of science were missing in the students' reflections. All of the interviewed students believed that the genetic content in the textbooks is a mirror the outcomes of science. Hence most students did consider the textbook definition of the gene as a simplistic, less complex version of the scientific.

CONCLUSIONS

From the interviews three main conclusions can be drawn:

- Students have difficulties in detecting the use of multiple models and the conceptual change that occur in a content specific context such as gene function.

- Students do not recognize the existence of conceptual incoherence between different models. If detected it is often regarded as flaws of the textbook.
- The students look upon the different models as different levels of generalization of the phenomenon.

Since the results from the study show that students have severe difficulties in detecting the use of multiple models and the conceptual change that occurs, textbooks ought to provide students with explicit descriptions of models. It is important for students to be aware of: that multiple models can be used to represent a phenomenon; the models fundamental differences; the models contextual use; and possible limitations. To be able to understand this it is crucial to know that the models are human constructs representing different scientific frameworks. An understanding of models and modeling among students is emphasized by many steering documents (The Swedish National Agency for Education, 2009; AAAS 1993), but as have been shown difficult to put into practice if current textbooks are used as the foundation of teaching genetics (Gericke and Hagberg, 2009). This might be a problem since textbooks are established as one the most influential aspects in the planning and execution of biology lessons (Moody, 2000).

ABSTRACT

In the paper introduction of an interdisciplinary practically oriented course at the Faculty of Electrical Engineering at University of Ljubljana is described. The introduction of the course named Project work and communication in research and development (R&D) has filled the gap in soft skills knowledge of young engineers. The course was taught for three times and was well accepted by the students. Even if it was an elective course at post-graduate study, it was chosen on average by 37,48% of all inscribed students. The trend of the percentage of participating students was rising. The survey among participating students showed that they were satisfied with the content of the course and the teaching approach.

Keywords: *Project management, communication, innovation, problem solving, team work, soft skills, engineering school*.

INTRODUCTION

In today's world, technology is developing very rapidly and most of businesses are getting more and more interdisciplinary (e.g. ICT – the sector where telecommunications and information technologies meet, telemedicine – the emerging sector where medical sciences meet ICT,…). The reason for that can be found in so called "open innovation approach" where new innovative products, technologies and services emerge as a mix of different technologies. On the other hand, one can realize that the research and development projects are no longer isolated processes. They are fully integrated into the corporations in the modern business environment. Projects are mostly even incorporated into more then one company. They are connected to each other and to other business processes in the business system. This is why they need special preparation, management, precise project organization, adapted information support, correct documentation, a special organizational culture, etc.

In most countries the educational system is lagging behind the changes in the business world and universities are still too specialized and "technically oriented". European Commission is getting more and more aware of the facts stated above. Therefore several proposals for improvements of European universities were published (Europa Press Release, 2006).

To prepare the students for work in real business life it is not enough bring them just the new knowledge in form of “cooking recipes” Therefore, it is important to teach students how to acquire newly developed and disseminated knowledge on their own with the help of knowledge technologies (Urbančič, 2007). In the business world, teamwork and networking is becoming more and more important since it brings together different individuals with specific knowledge and personal characteristics. Therefore engineering schools should move more to the direction of teaching “how to tackle a problem” rather than teaching specialized knowledge. Modern university programs usually include many “non-engineering” courses like network intelligence (Palmer, 1998) or creativity and collaboration (Burns and Jordan, 2006).

Young graduates from engineering schools are seemed to be lacking “soft skills” the most (i.e. social and managerial skills, as well as skills related to innovation). Many studies found out that innovation and other soft skills are very important in today’s world and universities should hand these on to students (Likar, 2009, Gider and Urbančič, 2010). To fill that gap, a new interdisciplinary course “Project work and communication in R&D” has been developed at the Faculty of Electrical Engineering at the University of Ljubljana. The main idea of the course was to give the students possibility to gain hands-on experience in conducting research projects by combining knowledge from different backgrounds: conducting research through the study of scientific literature, writing and presenting the results of their work, project management, creativity problem solving in teams and innovation. To make the course as practical as possible, the course was taught by experienced interdisciplinary team of specialists in the fields of project management, written and spoken communication, innovation, and problem solving in teams.

METHODOLOGY

Organisation of the course

The course “Project work and communication in research and development (R&D)” was launched in the academic year 2004/05 as an elective course within the master study program at the Faculty of Electrical Engineering of the University of Ljubljana. The course was on program every second year, all together carried out for 3 times. It has been chosen on average by more than one third of all inscribed students (see the table 1).

In one execution of the course all together 40 contact hours were given to the students. Besides that, the students worked on their own assignments for approximately 20 hours. The contact sessions were carried out in blocks of 4 hours each to optimise the time needed for the completion of the course (all the students were full time employed). The blocks were scheduled on Friday afternoons and Saturday mornings.

The course was divided into four individual modules, which discussed four different, but interrelated topics. The details of the modules are explained below.

A. Innovation management. The module included innovation goals, innovation culture, techniques for innovation boosting, intellectual property rights (IPR), patents, models, integrated circuit topology, registration procedures for IPR, use of web-based tools.

B. Communication in R&D. The module included R&D results presentation, time allotted and audience, collecting and selecting data and information, deciding on the main message, selecting evidences, preparation of visual aids and handouts, planning the presentation and rehearsal, critical evaluation of the performance, answering to questions, writing the abstract, the purpose and structure of the abstract, critical evaluation, communicating through poster, structure and design of a poster, scientific writing, publication structure and basic rules, illustration in scientific papers.

C. Project management. The module included project goals, project phases, basic and specific project goals, duration, project timeline, project resources, project database, planning and scheduling, project monitoring, prediction, decision making and assessment of R&D projects, use of dedicated software packages.

D. Problem solving in teams. The module included team work, roles of team members, tools and techniques for team work, problem definition, root cause analysis, definition of potential solutions, decision making on solutions, solution implementation, business case presentation.

Teaching methods

The faculty for the course consisted of 4 teachers. They came from 4 different universities and had extensive experience in business world in their respective fields (3 of them also successfully run their own firms). During the course, different teaching techniques were used: lectures (approx. 30% of total workload), case studies (10%), practical work in teams (30%) and individual (10%), questions and answers sessions (10%), and homework (10%).

The main features of teaching methods were as described below.

1. Traditional ex-cathedra lectures were combined with modern pedagogical approaches (practical exercises, case study, the study of examples, discussions, ‘hands-on’ experiments, role-plays, simulations…).
2. The lecturers are also practitioners, therefore they could simple switch between theoretical knowledge and practical experience which was very good accepted by the students.
3. From knowledge towards competence: the study concept was focused on both – education process and competencies acquiring (e.g. team work, project work, problem defining and solving, critical analysis, creative thinking etc.).
4. the e-learning tool was an integrated part of the course.

Student exercises

During the course the students worked on four individual and/or team tasks, as follows: (1) students filled a questionnaire on innovation culture in their organisations; (2) students performed current innovation culture status analysis and prepared improvement activity plan; (3) students prepared a project plan for the improvements of innovation culture; and (4) students prepared an abstract of scientific paper.

Two most important focuses of the course were on innovation management and project management. The student exercises related to those focuses are described in the following sections.

Exercise 1: Improvement of innovation and business performance

One of important pedagogical approaches within the subject was a case study representing an interesting model for university-industry cooperation. The aim was to prepare a strategy for business improvement of the organization. The concept was based on modern theory, research results, concrete analysis within the company, strategy prepared by the students and the professors' coaching. It is worth mentioning that the participating professors are experts and researchers on the case study topic publishing in world best journals and professional advisers as well with experiences in best international consulting organizations. The methodology was done in the following steps:

Step 1: Students were asked to perform an Innovation performance research within their company and prepare a short evaluation report. The reports were conducted by using the methodology, which was developed by the teachers. The main areas of evaluation were as follows: Vision and strategic aspects of encouraging innovation; Defining goals and measuring results; Organizational culture and climate; Innovation expenditure; The role of managers; Training and developing employees' competencies; Organizing the idea management processes; Identification of opportunities and generation of inventions; System of material and immaterial rewards; Co-operation for innovation / managing open innovation; The role of communication and sophisticated IT; Factors which inhibit innovation; Measurable results of innovation. Based on the results and theoretical/practical aspect presented within the lectures, the students identified an area(s) where additional efforts could lead to business performance improvement. These areas represented a starting point for the following activities.

Step 2: Collection of data – in order to be able to solve the problem students had to collect relevant data for further analysis.

Step 3: Definition of problem - search for root-causes of the problem.

Step 4: Idea collection – brainstorming for possible solutions.

Step 5: Evaluation of ideas and selection of ideas to be implemented.

Step 6: Planning – preparation of action plan.

Step 7: Presentation of chosen ideas to decision-makers in the firm.

Step 8: Action – implementation of ideas and follow-up.

Exercise 2: Conception and planning of R&D project

We know that R&D projects have to be integrated in the (business or any other) system. Actually projects are only specific way of organizing specific processes. Their main characteristic, in comparison with the other business processes running in the company or institution, is that projects are non-repetitive processes. Due to this, they require special preparation (conception and planning) each time.

We put special attention to the preparation process of the project in our lectures and workshops. Students had to prepare the concepts of development or research projects. They had to define the project purpose, project objectives, and constraints of the project. In the project charter, each student had to develop the content of the project and create the Work Breakdown Structure.

The concepts have been carefully reviewed by the mentor.

The second phase of the workshop was held in small teams. The students independently, based on their concepts, develop project plans. MS Project software tool was used for planning. They define the project phases and project activities, identify the duration of each activity, create network plan, and calculate the duration of the project and project calendar. They identify available resources and assigned them to activities. They optimize resource load (or found overload). Finally they calculate the cost of the project and the cost dynamics.

The project plans have been discussed in teams and reviewed by the mentor.

Evaluation of student satisfaction with the course

The satisfaction of students with the course has been evaluated after each execution of the course. The students answered the questions in the questionnaire, which is presented in the table 1. The questionnaire was divided into three parts: first part consisted of eight questions about the organization of the course, second part consisted of five questions about the content of the course, and third part consisted of questions for each module about the quality of teacher.

Table 1: Questionnaire for the evaluation of student satisfaction

Part 1: Organization of the course - Each question to be evaluated with grades from 1 (poor) to 5 (excellent)
1. The actual content of the course corresponds to the announcement content. 2. Information related to the execution of the course was adequate in content and timing. 3. The time of the course was adequate (days, dates, hours). 4. I regularly participated on the contact hours. 5. My expectations are fully met. 6. I would choose the course again, or recommend it to my colleagues. 7. All modules (A, B, C, D) were represented in the right proportions. 8. The course „Project work and communication in R&D" is the best.
Part 2: Content – open questions
9. State the content which could be omitted: 10. State the content which you missed: 11. State your positive experience with the course / professors: 12. State your negative experience with the course / professors: 13. My other comments:
Part 3: Evaluation of individual modules - Each question to be evaluated with grades from 1 (poor) to 5 (excellent)
A. Innovation management (B. Likar) A1. The teacher was well-prepared for the lectures. A2. The teacher is an expert in the field. A3. The teacher was accessible during the course. A4. The content of the module should be expanded in relation to the other modules. B. Communication in R&D (D. Miklavčič) B1. The teacher was well-prepared for the lectures. B2. The teacher is an expert in the field. B3. The teacher was accessible during the course. B4. The content of the module should be expanded in relation to the other modules. C. Project management (T. Kern) C1. The teacher was well-prepared for the lectures. C2. The teacher is an expert in the field. C3. The teacher was accessible during the course. C4. The content of the module should be expanded in relation to the other modules. D. Problem solving in teams (F. Gider) D1. The teacher was well-prepared for the lectures. D2. The teacher is an expert in the field. D3. The teacher was accessible during the course. D4. The content of the module should be expanded in relation to the other modules.

After the students filled the questionnaire, the results were analysed by using MS Excell spreadsheet software. For each question, mean grades have been calculated.

RESULTS

Number of students chosen the course

First measurement parameter of course performance was the rate of inscribed students, which have chose the course. Increasing percentage of inscribed students taking this course illustrates the interest of students in the skills, which were taught in the course (see the table 2).

Table 2: Number of inscribed students taking the course

Year	No of inscribed students	No of students in the course	Percentage
2001/02	64	17	26,56
2002/03	73	25	34,25
2003/04	81	22	27,16
2004/05	65	16	24,62
2005/06	71	23	32,39
2006/07	77	45	58,44
2007/08	74	34	45,95
2008/09	82	38	46,34
Total	587	220	37,48

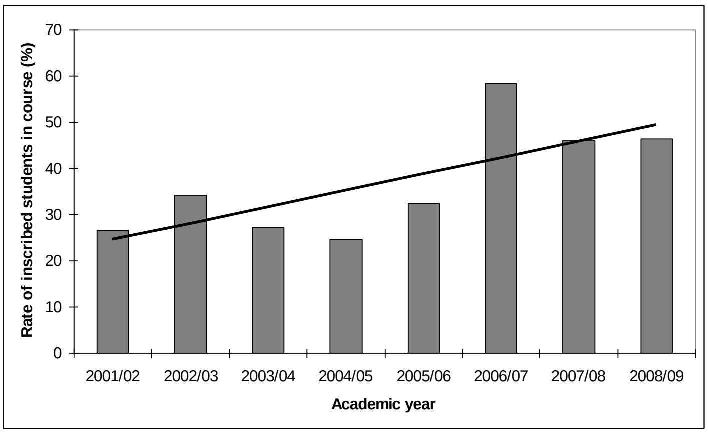

Figure 1: Percentage of inscribed students in course has increased

Attendance ratio

Second parameter of course performance was the presence of students in sessions. For students it was not obligatory to attend the sessions. The analysis showed that the presence on sessions was 66,67% of all students, who have chose the course. Given the fact that the sessions were held on Friday evenings and Saturday mornings, we can state that the interest of the students was relatively high.

Questionnaire results

Third parameter of course performance was the feedback of students after the course. The results of each part of the survey are presented below.

Organization of the course

In the first part of the survey the best grades were assigned to the question nr. 1, and the worst grades to question nr. 3 (see table 3). The results of the first part of the survey suggest that the course in general met the expectations of the students. During the execution of the course the time of sessions was the most inconvenient factor.

Table 3: Results of first part of student survey

Nr.	Question	Grade
1	The actual content of the course corresponds to the announcement content.	4,79
2	Information related to the execution of the course was adequate in content and timing.	4,55
3	The time of the course was adequate (days, dates, hours).	3,79
4	I regularly participated on the contact hours.	4,45
5	My expectations are fully met.	4,33
6	I would choose the course again, or recommend it to my colleagues.	4,73
7	All modules (A, B, C, D) were represented in the right proportions.	3,97
8	The course „Project work and communication in R&D" is the best.	4,06

Content of the course

On the second part of the survey, the answers could be summarized as follows:

Question 9: State the content which could be omitted – approx. 10% of answers suggested that innovation management and team work should be less focussed on.

Question 10: State the content which you missed – less than 10% of the students answered the question. Two most important ideas: writing business plans and more practical work with MS Project software tool.

Question 11: State your positive experience with the course / professors - the students liked the interactive approach with more teachers; cases and exercises during the sessions rather the boring “ex-catedra” teaching; relaxed atmosphere, humour during the sessions; real-life cases used as illustration of the content; cooperation between professors of four different universities.

Question 12: State your negative experience with the course / professors - timing of sessions (Friday evening, Saturday morning); too long sessions (4 hours); some topics could be expanded to more hours (project management); the course was too short to cover all the details of the topics chosen.

Question 13: My other comments – the answers suggested that the students had very positive experience with the course, some of the students suggest that also other engineering schools should consider such course, even in the graduate level.

Evaluation of individual modules of the course

The results of the third part of the survey are presented in the table 4. The results show that the students see the teachers as experts in their respective fields and think that the teachers were well prepared for the course.

Table 4: Results of third part of student survey

Nr.	Question	Grade
A1	The teacher was well-prepared for the lectures.	4,59
A2	The teacher is an expert in the field.	4,53
A3	The teacher was accessible during the course.	4,06
A4	The content of the module should be expanded in relation to the other modules.	2,78
B1	The teacher was well-prepared for the lectures.	4,94
B2	The teacher is an expert in the field.	4,78
B3	The teacher was accessible during the course.	4,66
B4	The content of the module should be expanded in relation to the other modules.	3,97
C1	The teacher was well-prepared for the lectures.	4,84
C2	The teacher is an expert in the field.	4,78
C3	The teacher was accessible during the course.	4,19
C4	The content of the module should be expanded in relation to the other modules.	4,25
D1	The teacher was well-prepared for the lectures.	4,77
D2	The teacher is an expert in the field.	4,57
D3	The teacher was accessible during the course.	3,93
D4	The content of the module should be expanded in relation to the other modules.	3,47

DISCUSSION OF FINDINGS, CONCLUSION AND RECOMMENDATIONS

The course “Project work and communication in R&D” was well-accepted by the students which can be seen from increasing number of students, which have chosen the course over the period of 8 academic years. Also the attendance ratio of the students at the sessions is very positive, given that the sessions were held on Fridays afternoon and Saturdays morning.

From the analysis of the questionnaire we can conclude that the expectations of the students were met in general. The students liked informal atmosphere (with humour) during the sessions. Usefulness of the knowledge and experience, which was taught at the course, was emphasised by practical exercises and team work of the students. The disadvantages of the course could be summarized as follows: the timing of the sessions was not appropriate, and the ratio of hours spent on individual modules should be modified.

For the next executions of the course we should consider the following experience draw from the analysis described in this paper:

1. The content of the course should be revised. The results of the study suggest that the students would expect more balanced content (i.e. more emphasis on the project management and less on innovation management and team work.
2. The sessions should be carried out during the week. Since all the students are employed full-time during the course, the most appropriate solution seems to be shorter sessions (e.g. 2 hours) during the week in the evenings.
3. Some student answers suggest that the course was too short to cover all important aspects of respective modules. An option could be that out of the course described in this paper two separate courses would be developed. One course could be on communication and project management, the other course on problem solving in teams and innovation management. By doing that, the courses could offer more in-depth focus on respective topics with special emphasis on practical exercises.

In general, one could state that the course “Project work and communication in R&D” has been successfully implemented at the Faculty of Electrical Engineering at the University of Ljubljana. With some minor changes the course could even develop further and gain more on its quality.

ABSTRACT

The various modalities of integrating Information and Communication Technologies (ICT) in science teaching and learning, as well as the potential and constraints that have emerged from implementing this in the educational context are some of the concerns addressed by an ongoing study in Education at the University of Aveiro. The aim of this study is to develop, implement and evaluate an in-service primary teacher education program for the integration of ICT in the teaching and learning process in general, and in science teaching and learning in particular. The study follows a qualitative research methodology, from an action-research approach. This paper focuses on the first phase of the study, which dealt with the selection of “strategies” and “technology-rich activities” for implementation in an in-service teacher education program at the University of Aveiro and discusses potential barriers to provide in-service primary teachers with integrated technological and pedagogical experiences. It is our ultimate goal, once the study is concluded, to put forth in-service primary teacher education programs in science education based on optimal guidelines derived from data. A complete description of the research methodology, as well as results achieved in this research phase, is put forward.

Keywords: *Sciences teaching methodologies, ICT, sciences learning, teacher education program*

INTRODUCTION

This study is based on three essential premises for science and technology education worldwide, which emerged from the Perth Declaration on Science and Technology Education in 2007 (Fensham, 2008). The first premise is related with the traditional role of science in school, namely motivating pupils to learn sciences, which could be a way to engage them in further studies for careers directly involved with science and technology issues (Harlen, Macro, Reed & Schilling, 2003; Osborne & Dillon, 2008). The second premise is that all pupils need to be prepared to participate actively as individuals and as responsible citizens in our modern society (Osborne & Dillon, 2008). The third premise derives from the changes that Information and Communication Technologies (ICT) have on teachers’ daily work.

A number of researchers have carried out extensive studies on the benefits of ICT use in teachers’ professional lives. Particularly, teachers’ use of ICT tools can improve practical and experimental teaching and learning of sciences. ICT also offers the possibility of interacting with technological and scientific phenomena through simulations, searching for and locating scientific information in online databases, and communicating and collaborating with peers, teachers and scientific experts (Arnold, Padilla & Tunhikorn, 2009; Juuti, Lavonen, Aksela & Meisalo, 2009; Minchi, Michael & Lynn, 2007; Webb, 2005). In this view, teachers should know "where and when (as well as when not) to use the technology for classroom activities and presentations, for management tasks, and to acquire additional subject matter and pedagogical knowledge in support of the teachers' own professional development" (Khan, 2008, p. 6).

However, some researchers have identified several obstacles that explain why science teachers do not integrate ICT in teaching and learning processes. These obstacles include the lack of hardware and software in schools, insufficient teacher education programs in the use of ICT and their applications in science classrooms, and teachers' technophobic attitudes (Guzey & Roehrig, 2009; Juuti, Lavonen, Aksela & Meisalo, 2009).

Koehler & Mishra (2009) say that many teachers had their degrees at a time when educational technology was at the beginning stage of development. Therefore, these authors stressed that "It is, thus, not surprising that they do not consider themselves sufficiently prepared to use technology in the classroom and often do not appreciate its value or relevance to teaching and learning" (Koehler & Mishra, 2009, p. 62). Consequently, higher education institutions should face the development/improvement of pedagogical competences in ICT of the teachers as a continuous process, where the initiation to the pedagogical uses of ICT should be integrated into teacher education programs, as a dynamic and evolving process of professional development of students and in-service primary teachers.

The background of European higher education institutions has changed considerably in recent years, since the implementation of the Bologna Process, as part of a strategy designed to build a European Higher Education Area (EHEA). As a result, Primary Teacher Education programs (undergraduate and postgraduate degrees) were restructured, throughout Portuguese universities and polytechnic institutions, in order to conceive educational opportunities to help students and in-service teachers to develop various pedagogical competences. In this context, the University of Aveiro (Portugal) created a Master's degree in Science Education (2nd Cycle), specifically designed for in-service primary teachers who want to develop/improve their professional knowledge related to science teaching and learning practices. Teachers' professional knowledge is related to several domains, those of knowledge and teaching practice, as well as other professional roles, both inside and outside the classroom, including tutoring, participating in school activities and projects, interacting with members of the community and working in professional groups (Arnold, Padilla & Tunhikorn, 2009; Juuti, Lavonen, Aksela & Meisalo, 2009).

The reorganization of this postgraduate course adhered to EHEA's underlying principles of curricular flexibility, quality and life-long-learning, with the purpose of developing in-service primary teachers' professional knowledge so as to ensure that their pupils will learn sciences better. These in-service primary teachers are simultaneously primary teachers who work with 4 to 12 year-old pupils. The Portuguese legislation for the general profile of teachers' professional performance, such as bills 240/2001 (August 30) and 241/2001 (August 30), refer pedagogical competences in ICT. Therefore, the Master's degree in Science Education included the development and/or improvement of pedagogical competences in ICT of the in-service primary teachers in curricular areas such as “Sciences Teaching Methodologies” and “ICT in Science Education”. The main educational purpose of these curricular areas is to develop in-service primary teachers’ pedagogical competences in ICT.

This study is based on the assumption that it is crucial to develop, implement and evaluate innovative “strategies” and “technology-rich activities” to enhance primary science teachers’ use of ICT, particularly in postgraduate degrees. In this view, it is fundamental to understand which “strategies” and “technology-rich activities” could be put into practice in the curricular areas related to “Sciences Teaching Methodologies” and “ICT in Science Education” at the University of Aveiro Master’s degree in Science Education (2^{nd} Bologna cycle). In this context, it is important to find answers for the following research questions: “What are the optimal guidelines to be adopted for a in-service primary teacher education program, in order to contribute towards the development of primary teachers’ competences in science teaching with and through ICT?”; “What is the impact of the in-service primary teacher education programme thus developed in the primary teachers’ professional knowledge?”.

LITERATURE REVIEW

Outcomes emerged from the specialized scientific community in Education (eLene, 2008; Khan, 2008; Wang, 2008), as well as the underlying principles of Bologna (González & Wagenaar, 2008), and the Organisation for Economic Co-operation and Development (OECD) recommended the integration of ICT into the curriculum plans of Teacher Education Programs. This was based on the assumption that teachers are catalysing agents of “educational change” in schools and ICT could take an important role in this context.

Many studies have shown that the integration of ICT in science teaching and learning can improve pupils’ understanding of scientific and technological concepts (Barton, 2004; Beauchamp & Parkinson, 2008; Eijck & Roth, 2007; Harlen, Macro, Reed & Schilling, 2003; McFarlane & Sakellariou, 2002; Murphy, 2003). For instance, Barton (2004) says that ICT can help pupils and teachers: to deal with abstract ideas and concepts about science and technology; to visualize dynamic processes and complex interactions; to experiment and investigate about scientific and technological phenomena; to look for the relationships between variables (practical work) and to process mathematical data. ICT can also offer the possibility of searching for and locating scientific information in online databases, or communicating and collaborating with peers, teachers and experts.

Several researchers put forward the idea that primary teachers should be engaged with ICT in their practices, within wide social and cultural contexts, because digital educational resources could support both the investigative (skills and attitudes) and more knowledge-based aspects (concepts) of the pupils (Barton, 2004; Harlen, Macro, Reed & Schilling, 2003; Murphy, 2003). According to van Eijck & Roth (2007), the integration of ICT-based research tools in science teaching could facilitate the promotion of pupils’ active participation in inquiry. ICT-based research tools include hardware (i.e. sensors for data collection) as well as software (i.e. simulations). These authors also consider that the role of ICT-based research tools could contribute towards the development of pupils’ scientific literacy. Additionally, the integration of e-learning platforms, Web 2.0 tools (i.e. blogs, podcasts) and mobile instruments (i.e. phones) in the teaching and learning process might improve students’ learning about several subjects (Redecker, 2008), such as sciences.

In this view, primary teachers should be able to structure problem-tasks and integrate ICT tools with pupil-centred teaching methods, and play an important role in creating and implementing a vision of school as a community based on innovation and continuous learning of sciences, enriched by ICT (Barton, 2004; Harlen, Macro, Reed & Schilling, 2003; Murphy, 2003). Nevertheless, in order to make effective use of ICT "… teachers need to believe not only that affordances of these environments can support their students' learning but also that they themselves have a crucial role in planning and managing the learning experiences…" (Webb, 2005, p. 733). Therefore, it is vital to develop/improve the pedagogical competences in ICT of students and in-service primary teachers (undergraduate and postgraduate degrees, respectively).

The United Nations Educational, Scientific and Cultural Organization (UNESCO) published the "ICT Competency Standards for Teachers (ICT-CST)" framework with guidelines for the development of teacher education programs. The framework refers the competences to be developed by teachers and within each competence it details different teaching and learning methodologies (Khan, 2008). The standards proposed by UNESCO were based on three approaches to education reform: a) *technology literacy* - increasing the technological uptake of the workforce by incorporating technology skills in the curriculum; b) *knowledge deepening approach* - increasing the ability of the workforce to use knowledge to add value to economic output by applying it to solve complex, real-world problems; c) *knowledge creation approach* - increasing the ability of the workforce to innovate and produce new knowledge and of citizens to benefit from this new knowledge (Khan, 2008).

The development of *technology literacy* cited in UNESCO ICT-CST usually takes place under a technical training perspective, which is related to the mastery of the technical instruments and computing tools, from a more instrumental perspective (Khan, 2008). However, several authors stress the idea that these technological competences shouldn't be developed as separate from the pedagogical aspects related to the use of ICT in teaching and learning processes. Consequently, teachers should develop/improve pedagogical competences related to the integration of ICT into the curriculum, which in turn will help them explore technology to help pupils collaborate, access information, communicate with external experts, share, analyze and solve problems, as well as to learn throughout their lives. This underlying approach is harmonized with the UNESCO ICT-CST framework, in which competences related to *the knowledge deepening approach* should include the competences of teachers in promoting, for instance, individual pupil and group project work. Additionally, it should enable collaboration with other teachers and foster the use of networking tools to support their own professional development (Khan, 2008). Finally, in the UNESCO ICT-CST framework, teachers who show competence within the *knowledge creation approach* will be able to design ICT-based learning resources and environments so as to support the development of knowledge creation and critical thinking skills of pupils, and create knowledge communities for pupils and colleagues. This level of training will play an important role in creating and sustaining a vision of the school as a community based on innovation and continuous learning, enriched by ICT (Khan, 2008).

In this context, primary teacher education programmes should be based on the concept of learning outcomes, which are statements that emerge from the Bologna principles, which describe what a student or in-service teacher is expected to know, understand and/or be able to demonstrate at the end of a degree (undergraduate and postgraduate). Therefore, teaching and learning activities should be synchronized with the learning outcomes and should move from a teacher-centred approach (focused on what the teacher does) to one that should be centred on student involvement in the learning process (González & Wagenaar, 2008).

As to the development/improvement of students' competences, members of the Joint Quality Initiative (JQI) proposed a set of descriptors, called the Dublin Descriptors, which have been established for 1st, 2nd and 3rd Bologna cycles. According to these descriptors, after each degree cycle, students are expected to have attained a certain level of competences across five broad learning outcomes: knowledge and understanding, application of knowledge and understanding, making judgments, communication and learning skills (González & Wagenaar, 2008).

The Dublin Descriptors are related to all curricular areas and define attributes such as problem solving, communication, writing, research, and teamwork competences of the students. Therefore, at the end of each cycle, students should have the ability to gather and interpret relevant data related with their field of study in order to inform judgements that include reflection on relevant social, scientific or ethical issues. It is also important that students can communicate information, ideas, problems and solutions to both specialist and non-specialist audiences. Finally, students should develop those learning competences that are necessary for them to continue to undertake further studies with a high degree of autonomy(González & Wagenaar, 2008).

In this higher education context, curriculum areas should include the following aspects: a) types of teaching and learning activities (i.e. lecture, seminar, tutorial, project work, etc.); b) types of learning activities (i.e. attending lectures, practising technical or laboratory skills, chairing meetings, etc.); c) types of student assessment (i.e. oral presentation, paper/essay, portfolio, report on fieldwork, continuous assessment (i.e. final thesis/dissertation, etc.) (González & Wagenaar, 2008). A social constructivist framework for innovation design of curricular areas has been described by Ferdig (2006). According to this author, and based on the research of Salomon (1993), innovations must congregate academic content and practice in order to create authentic and engaging activities for students. Then, innovative design should include five components. First, innovation must contain authentic, meaningful and real-word problems that engage students in learning. Second, students should have the opportunity to take on a self-regulating role in their learning process. Third, a pedagogical innovation should be imbued with opportunities for active participation, collaboration and social interaction of students. Fourth, pedagogical innovations must afford opportunities for the creation of artefacts. Those artefacts should represent students' understanding of the problem, resulting solutions and emergent states of knowledge. Finally, innovations should stress the importance of publication, reflection and feedback.

Moreira & Loureiro (2008) suggest the articulation between Learning/Technology/Interaction in in-service teacher education programs, which could improve the relationships between students and teachers, between them, the learning content and the technological tools, so as to achieve improved students' learning outcomes. In this context, technological and pedagogical content knowledge (TPCK) should be the basis of effective teaching with technology. This should require "an understanding of the representation of concepts using technologies; pedagogical techniques that use technologies in constructive ways to teach content; knowledge of what makes concepts difficult or easy to learn and how technology can help redress some of the problems that students face; knowledge of students' prior knowledge and theories of epistemology; and knowledge of how technologies can be used to build on existing knowledge to develop new epistemologies or strengthen old ones" (Koehler & Mishra, 2009, p. 66).

Brush & Saye (2009), based on Lee (2008), focus on a set of guidelines for effectively integrating TPCK into a social studies context, such as: locating and adapting digital resources for use in the classroom; facilitating students' work in nonlinear environments; using the Internet to extend collaboration and communication among students; extending and promoting active and authentic forms of human interaction and technology enabled social networks.

A complete description of the research methodology as well as results achieved in this research phase will be put forward in the following sections.

RESEARCH METHODOLOGY

A qualitative research methodology, through an action-research approach, was adopted in this study. The research process was organized in the following steps: to identify the research objectives of the data collection instruments; to review literature, pertinent to the research objectives of the data collection instruments; to organize the corpus of analysis from the several tasks (1st and 2nd tasks); to develop a data analysis instrument; to categorize the data in defined dimensions, sub-dimensions and categories of analysis; and to have the data analysis instrument validated by a panel of experts in teacher education programs, with pedagogical competences in ICT.

Table 1 summarizes the techniques and instruments of data collection and analysis adopted in each research task.

Table 1 - Techniques and instruments of data collection and analysis

Task	Data Collecting			Data Analysis
	Techniques	Instruments	Participants	Techniques
1st Task	Document analysis	Document analysis instrument	Researcher of the study	Content analysis
	Inquiry	Semi-structured interview	4 national ET researchers	Content analysis
2nd Task	Observation	Research diary	Researcher of the study and 2 teacher-trainers	Content analysis

The **1st task** occurred from January 2009 to November 2009, and comprehended two data collection moments. The aims of this task were: to understand which pedagogical and technological competences should be developed in primary science teacher education programs (under and postgraduation degrees); to identify the main programmatic areas in Educational Technologies that could be articulated with sciences teaching and learning; to define which teaching and learning perspectives could be implemented in sciences teaching and learning; and to identify the learning evaluation perspectives which could be adopted to assess students' learning outcomes in this context.

In the first moment, several programs of curricular areas related to Educational Technology (ET) (i.e., "ICT in education") were analysed from an exploratory point of view. Data were obtained from "Basic Education" degrees (1st Bologna cycle), offered by Portuguese public higher education institutions (7 universities and 13 polytechnic institutions). Document analysis was adopted in this task because it was an unobtrusive technique and it was used without imposing face-to-face participation of the teacher-trainees who developed the curriculum programs. In a second moment, four national educational technology researchers were interviewed. The researchers were specialized in the development of primary teacher education programmes (undergraduate and postgraduate degrees) and one of them was an expert in science education research. The semi-structured interview had predefined open questions, but further questions were used by the interviewer during the conversations with the researchers (Bardin, 2000; Bauer, 2000).

In the **2nd task**, a case study was undertaken in the curricular areas of "Sciences Teaching Methodologies" and "ICT in Science Education" of the University of Aveiro Master's degree in Science Education (2nd Bologna cycle). The aim of this task was to describe and understand the development process of the in-service primary teacher education program, with the aim of articulating those two curricular areas in order to contribute towards the development of primary teachers' competences in science teaching with and through ICT.

This task comprehended one data collection moment, which occurred from December 2009 to January 2010, through participant observation performed by the researcher during the collaborative work with the two teacher-trainers of those curricular areas. The teachers-trainers were asked to participate in this project, based on their formative and research interests, as well as the interest of the Master's degree in Science Education (2nd Cycle), which was specifically designed for in-service primary teachers who want to develop/improve their professional knowledge related to science teaching and learning practices. Collaborative work between the researcher and the teacher-trainers occurred in four face-to-face sessions and through online interactions on a social network platform (Ning). This process proved to be an efficient communication medium between all the elements of the team. Each of the curricular areas had its individuality, mainly in terms of *subject area* ("Sciences Teaching Methodologies" and "ICT in Science Education"). Collaborative work focused on the reflective discussions between the researcher and the teacher-trainers, articulating the "guidelines" that emerged throughout the first phase of this study, the literature review about the subject area, and the respective learning outcomes previously envisaged for each of those curricular areas. Research diaries were produced by the researcher along this task, which included two levels of information: descriptive and reflective. The descriptive level addressed facts about date, place, participants and activities developed (all sessions were audio-recorded and transcribed). The reflective level aimed to reflect preliminary outcomes of the study, from the researcher's point of view.

Data were analysed from an exploratory point of view under a content analysis methodology. A descriptive methodology was implemented through a *nomothetic* approach, in order to identify underlying trends and/or patterns in the collected data (Bardin, 2000; Bauer, 2000). The dimensions, sub-dimensions and categories of analysis were established based on the research aims and supported by the literature review, specifically the recommendations made by the EHEA (González & Wagenaar, 2008) and the primary teacher education profile proposed by the Science Education scientific community as to the use of ICT in teaching and learning (Arnold, Padilla & Tunhikorn, 2009; Juuti, Lavonen, Aksela & Meisalo, 2009; Minchi, Michael & Lynn, 2007; Webb, 2005).

RESULTS AND DISCUSSION

In the **1st task**, data analysis showed that it is important to develop/improve *primary teachers' innovative pedagogical competences in ICT*. This result emerged from content analysis of the programs of the curricular areas related to ET, an aspect also suggested by two of the members of the national educational technology researchers interviewed. This level of *pedagogical competences in ICT* could allow in-service primary teachers to develop critical thinking in order to reflect about their own professional practices, incorporate research in their sciences teaching and learning activities and expand pedagogical innovations in the classroom within the educational community (Khan, 2008). Several authors defend that this type of *innovative pedagogical competences in ICT* should be developed through teacher education programs at a postgraduation level (2nd and 3rd Bologna Cycle) (Costa, Rodrigues, Peralta, Cruz, Reis, Ramos, Sebastião, Maio, Dias, Gomes, Osório, Ramos & Valente, 2008).

However, two other experts suggested that it is important to identify training needs of the in-service primary teachers. In fact, one of the obstacles that explain why primary teachers do not integrate ICT in teaching and learning processes have to do with the lack of (i) teacher education programs in the use of ICT and (ii) the reduced application of technologies in science classrooms, as well as teachers' technophobic attitudes (Guzey & Roehrig, 2009).

Content analysis also allowed identifying the *main programmatic areas in ET that could be articulated with sciences teaching and learning*. These were: locating and adapting ICT tolls for use in the sciences classroom; facilitating in-service primary teachers' work in nonlinear environments; using the Internet (i.e. social networks) to extend collaboration and communication among in-service primary teachers and their teacher-trainees (or other colleagues).

Data analysis showed that it is important to promote inquiry-based learning activities in science classrooms *with* and *through* ICT-based research tools. This *teaching and learning approach* could be a promising way to promote in-service primary teachers' pedagogical competences in ICT and could contribute for the development of their pupils' scientific literacy (Eijck & Roth, 2007). Finally, data analysis showed that *continuous and formative assessment* should be adopted to assess in-service primary teachers' learning outcomes. This could be achieved trough the development of several instruments by the in-service primary teachers themselves, such as presentations, scientific papers, digital portfolios and reports on fieldwork (González & Wagenaar, 2008).

Data obtained from the **2nd task** helped apply an innovative design of the curricular areas of "Sciences Teaching Methodologies" and "ICT in Science Education" (Ferdig, 2006). The in-service primary teacher education program was offered in a blended-Learning regime, comprising two face-to-face sessions per week – one in "Sciences Teaching Methodologies" and another in "ICT in Science Education". In between those face-to-face sessions, distance work took place throughout the week.

The team discussed and selected the following innovative strategies to be implemented concurrently to each curricular area (Ferdig, 2006): to provide authentic, meaningful and real-word problems to the in-service primary teachers and thus engaging them to sciences and technological learning with and through ICT; to give the opportunity to the in-service primary teachers to take on a self-regulating role in their learning process; to afford opportunities for active participation, collaboration and social interaction of the in-service primary teachers; to afford opportunities for the creation of artefacts, which should represent in-service primary teachers' understanding of the problem, resulting solutions and emergent states of knowledge; to embrace the importance of publication, reflection and feedback.

These strategies involved the integration of several technology-rich activities into various aspects of the curricular areas. The aim was to promote in-service primary teachers' deep understanding of the multiple technology tools (hardware and software) available (in their educational contexts and on the Internet), and to show them how those tools can be used to enhance a wide variety of activities in sciences teaching and learning.

One technology-rich activity was related to the exploitation of real case studies, conducted by primary teachers and researchers that promoted the integration of ICT-based research tools in science teaching and learning. These case studies were provided through the organization of several seminars organized in the curricular area of "Sciences Teaching Methodologies". Additionally, in-service primary teachers accessed scientific literature available online. The educational goal of this technology-rich activity was to allow in-service primary teachers to access and discuss the potentialities and constrains of ICT integration in science teaching and learning, and its role in facilitating the promotion of pupils' active participation in inquiry in sciences classrooms.

Another technology-rich activity aimed to provide in-service primary teachers with opportunities to implement small research projects that effectively utilize ICT-based research tools in their sciences classroom contexts. The ICT-based research tools should be available at their schools and/or accessible via the Internet. The educational goals of this activity were: to motivate in-service primary teachers to collaboratively design a technology-based activity for their pupils, implement and evaluate the effectiveness of that activity in pupils' understanding of scientific and technological concepts; to support in-service primary teachers' professional development enabling them to develop their practice, and connect with others in the field.

These technology-rich activities afforded learning opportunities to in-service primary teachers to explore several technological tools: Ning, with the aim of enhancing social networking between in-service primary teachers and their teacher-trainees; *box.net* with the aim of sharing available videos, audio/podcasts and scientific literature about research studies that endorse the integration of ICT-based research tools in science teaching and learning, etc.; MinMeister with the aim of enhancing collaborative mind-mapping in order to understand the representation of scientific and technological concepts using technologies; WordPress, a blogging tool with the aim of developing digital portfolios in order to give the in-service primary teachers the opportunity to take on a self-regulating role in their learning process. In-service primary teachers were asked to integrate their critical reflections, activity resources, and other artefacts in their digital portfolios. Additionally, in-service primary teachers should reflect upon how well the technology supported the goals of the activity and what modifications they would make to future iterations of the activity in their digital portfolios;

Pbwork, a wiki tool with the aim of collaboratively (in dyads) developing a scientific paper about the literature review and research methodology adopted in their research projects; mobile phones with the aim of improving in-service primary teachers' questioning skills about several subjects (they were asked to send reflective questions to the teacher-trainees, after each seminar); sensors with the aim of promoting practical and experimental activities in "Sciences Teaching Methodologies" and in "ICT in Science Education".

The seminars, the small research projects developed by the in-service primary teachers, as well as the experimental activities that were developed, are presently being audio and video recorded and shared in the social network (Ning) so as to provide in-service primary teachers with opportunities to explore the interaction of technology, pedagogy, and content, thus providing, we hope, optimal sciences learning environments.

In-service primary teachers' learning outcomes follow *continuous and formative assessment* approaches. This will be based on the scrutiny of products developed by the in-service primary teachers: a scientific paper (Pbwork); a digital portfolio (Blog); a concept-map (MinMeister); and the interactions in the Ning forums. Those products should represent in-service primary teachers' understanding of the problem, the resulting solutions and emergent states and increments of knowledge. According to Ferdig (2006), innovations should embrace the importance of publication, reflection and feedback. These products will allow teacher-trainees to infer the process by which in-service primary teachers transform meanings and strategies shared and co-constructed in the social network, making those strategies their own.

A symposium is being prepared, to take place at the end of the training programme, so that the in-service primary teachers have the opportunity to make public the results of their projects, but also and especially to allow them to share and discuss the strategies implemented and validated/assessed next to the national community of sciences teachers and researchers.

CONCLUSIONS

This study is based on the assumption that it is crucial to develop, implement and evaluate innovative strategies and technology-rich activities to enhance primary science teachers' use of ICT, particularly at postgraduation level.

This paper addresses which optimal guidelines were put into practice in the curricular areas related to "Sciences Teaching Methodologies" and "ICT in Science Education" at the University of Aveiro Master's degree in Science Education (2nd Bologna cycle). The development of synergies between the curricular areas of "Sciences Teaching Methodologies" and "ICT in Science Education" were underline at: the research level, where in-service primary teachers were asked to conduct research studies about real problems related to the teaching and learning process of sciences; at the professional level, where it was important to relate all subjects with professional practices of the in-service primary teachers; and at the curricular level, related to the formative dimension of teaching methodologies in postgraduate teacher training courses (i.e. education for sustainable development).

Finally, the central subject of each curricular areas aimed at developing *innovative pedagogical competences in ICT* related to in-service primary teachers' professional lives, namely (i) integrating ICT into sciences teaching practices; ii) promoting and exploring interaction practices when planning pedagogical activities (for formal and/or non-formal contexts); iii) developing collaborative work; and iv) developing research competences (Costa, Rodrigues, Peralta, Cruz, Reis, Ramos, Sebastião, Maio, Dias, Gomes, Osório, Ramos & Valente, 2008).

An in-service teacher education program was developed in order to improve the relationships between in-service primary teachers and teachers-trainees, between the learning content and between the technological tools, so as to achieve improved in-service primary teachers' learning outcomes (Moreira & Loureiro, 2008).

The strategies and technology-rich activities were designed to increase in-service primary teachers' TPCK by providing them with opportunities to explore innovative and emerging ICT-based research tools in authentic science teaching and learning contexts. As Koehler & Mishra (2009) stated, TPCK should be the basis of effective teaching with technology, which requires an understanding of the representation of concepts using technologies as well as pedagogical competences to integrate those technologies in constructive ways to teach content, such as sciences.

However, it is still necessary to evaluate the extent to which this knowledge transfers to actual classroom practices once these in-service primary teachers obtain their grades in those curricular areas. Consequently, it is imperative to find answers for the following research question: What is the impact of the in-service teacher education programme thus developed in the primary teachers' professional knowledge?

Therefore, the purpose of the second and third research phases of the study is to evaluate the effectiveness and mid-term impact of the in-service primary teacher education programme. Specifically, it is important to assess if the strategies and technology-rich activities adopted will develop/improve several pedagogical competences in ICT of those in-service primary teachers, such as: critical thinking in order to reflect about their own professional practices; incorporate research outcomes in their sciences teaching and learning activities; expand pedagogical innovations in the classroom within the educational community. The results of this later stage of the study will be the object of future writings.

ABSTRACT

The purpose of this study is to determine elementary school science pre- service teachers' critical thinking skills through the story of the Rapa Nui- Easter Island. The study was conducted in the fall semester of 2009-2010 academic year. Participants of the study consisted of 29 pre-service teachers; 21 females and 8 males, enrolling to elementary school science education department of one of the universities in Türkiye. To determine critical thinking levels, six open- ended questions were prepared by researchers based on six dimensions of critical thinking skills reported in Delphi project. Pre-service teachers were asked to read the story of Easter Island and answer six open-ended questions. Results of the study revealed that most of the pre-service teachers were efficient in categorization, examining ideas, drawing conclusions, stating results and self-examination. Besides, results also showed that most of the participants were not efficient in decoding significance, assessing arguments, justifying procedures, presenting arguments and self-correction.

Keywords: *Environmental education, critical thinking skills, pre-service teachers.*

INTRODUCTION

Rapid population growth and over consumption of resources produce increasing pressures on the Earth causing over-exploitation of non-renewable resources, and production of more waste that can be absorbed and processed by the nature (Environmental Protection Agency, 2003). This situation results in increasing pollution, poor air and water quality, and the extinction of numerous animal and plant species.

Today, environmental problems are experienced on a global scale and impact more and more of the human population. The deterioration of the global environment has become a leading concern for all communities and interest in environmental problems has increased both in international and national level. To determine the current situation of the planet Earth and find ways to solve environmental problems many meetings were conducted with the participation of attendees from different countries. In 1972, in one of these meetings, United Nations Conference on the Human Environment and Development (UNCHED), the term 'sustainable development' was established (Reed, 1996; Williams, 1993) with a hope of leaving future generations a world that is worth to live in it. The term came into common usage with the publication of the Brundtland Commission Report (World Commission on

Environment and Development [WCED], 1987). In this report the term is defined as "meeting the needs of the present without compromising the ability of future generations to meet their own needs" (Brundtland Commission, 1987). Sustainable development calls a redefinition of the relationship between man and the environment. It aims to find a balance between providing human needs with protecting the environment (Goldman, Yavetz & Pe'er, 2006). With this respect, sustainable living can be achieved by continuous evaluation of human needs in terms of their potential impacts on future generations (Brown, Flavin & Postel, as cited in Orr, 1992). The concept of sustainable development is multidimensional; it focuses on relationships between three areas; environment, society and economy, for the well being of human populations (Brundtland Commission, 1987). According to Goodland (1995), it incorporates the ability of each area to maintain itself without impacting the other areas in negative way. With this respect the goal of sustainable development is to provide secure economic development, social equity and justice, conserve natural resources and support environmental protection (Humphries, 2004). Sustainable development enforces us to think about the welfare of all species both today and tomorrow (Humphries, 2004).

Through the discussion and formulation of the concept of sustainable development, it became apparent that education is needed to accomplish it. Fien (2002) argues that education for sustainable development is a key component in addressing the challenge of sustainability. In the UNCHED report 'education for sustainable development' is defined as an "emerging but dynamic concept that encompasses a new version of education that seeks to empower people of all ages to assume responsibility for creating a sustainable future" (p.7). To achieve the aim of creating a sustainable future, there must be a paradigm shift in human behavior with respect to the environment. In order to make the shift we have to educate citizens who can realize environmental problems and produce solutions to solve them.

Critical thinking is essential in understanding, analyzing and interpreting environmental problems. There has been much debate among researches on the definition of 'critical thinking' (Kennedy, Fisher & Ennis, 1991). For this reason, there is no single and universally agreed definition of critical thinking. One of the most widely accepted definition of critical thinking is stated by Robert Ennis. According to Ennis (1987), "critical thinking is reasonable, reflective thinking that is aimed that at deciding what to believe or what to do" (n.p.). Besides, Chaffe (1988) stated that "critical thinking is making sense of our world by carefully examining our thinking, and the thinking of others, in order to clarify and improve our understanding" (p.5). In 1990s, American Philosophical Association assembled experts to reach a consensus on a definition and dimensions of critical thinking. This assembly, The Delphi Project, provided considerable insight and direction about critical thinking and characteristics of critical thinkers. In the Delphi Project (1990) it is stated that;

> *We understand critical thinking to be purposeful, self regulatory judgement which results in interpretation, analysis, evaluation and inference as well as explanation of the evidential conceptual, methodological, criteriological or contextual considerations upon which that judgement was based. Critical thinking is essential as a tool of inquiry. Critical thinking is a pervasive and self-rectifying human phenomenon. The ideal critical thinker is habitually inquisitive, well-informed, honest in facing personal biases, prudent in making judgements, willing to consider, clear about issues, orderly in complex matters, diligent in seeking relevant information, reasonable in selection of criteria, focused in inquiry, and persistent in seeking results which are precise as the subject and the circumstances of inquiry permit (p.4)*

While there are still disagreements about critical thinking, giving a precise definition is not in the scope of this paper. For the purpose of this study dimensions of critical thinking; interpretation, analysis, evaluation, inference and explanation and self-regulation, determined in Delphi Project (1990) are considered.

To improve children's critical thinking, schools must review what they are doing and what they are achieving. It is proved that critical thinking skills are not learned well unless teachers emphasize use of critical thinking skills during the teaching process (Howe & Disinger, 1990). To educate students as critical thinkers, teachers should have efficient critical thinking skills. With this perspective investigating pre-service and in-service teachers' critical thinking skills becomes very important. For this reason the purpose of this study is to determine pre-service teachers' critical thinking skills through an environmental story; Rapa-Nui.

PROCEDURE

Participants of the Study

The study was carried out in the fall semester of 2009-2010 academic year. Data of the study were obtained from 29 freshmen students; 21 girls and 8 boys, enrolling to the elementary school science education program of one of the universities in Türkiye.

Instrument

According to Howe and Disinger, "providing experiences in real life situations or situations that simulate real life situations increase the probability that critical thinking skills will be used" (p.4). Story of the Rapa-Nui Island provides a real life situation for pre-service teachers in which they can clarify the problems, deduce data needed to solve the problem, evaluate sources of information critically and develop solution strategies. Six open-ended questions were prepared by researchers based on the story of the Rapa-Nui Island. To determine the critical thinking skills, in a 30 minute period, pre-service teachers were asked to read the story about the Easter Island and answer the open-ended questions below.

1. Explain and list the environmental problems experienced Rapa-Nui Island.

2. Analyze the situation in Rapa-Nui by considering your beliefs, judgments and experiences.

3. Evaluate the events happened in Rapa-Nui.

4. How the problems experienced in Rapa-Nui can be solved? By considering the problems in the Rapa- Nui describe current environmental problems and their consequences.

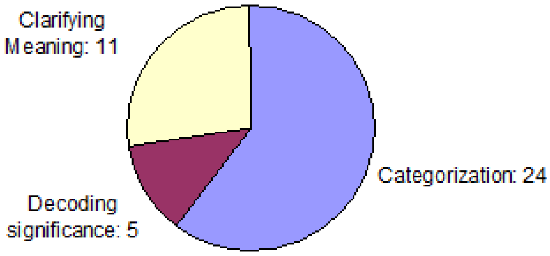
5. Summarize the situation in Rapa-Nui with your own wording.

6. Review the story and your responses then evaluate your performance.

Analysis of the Data

The participants' responses to the questions comprise the data set used for the analysis. The data obtained were analyzed by using content analysis procedures. Before coding, the researchers overviewed all the responses for each question to determine meaningful data units. Then, a list of codes was created by noting all the features included in the questionnaires. In the next step, these codes were put under the subcategories of critical thinking defined beforehand.

RESULTS



Interpretation:

When pre-service teachers' responses belonging to the skill of interpretation are examined, it is found that there are 24 expressions that can be covered by categorization sub-skill.

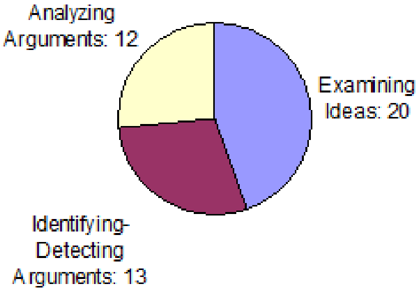
Example replies of pre-service teachers for the categorization sub-skill are as follows:

- Cutting of trees, loss of green areas, inability to process the land are some of the environmental problems experienced in Rapa-Nui.
- Limited amount of natural resources, resource depletion and conflicts experienced because of these problems
- Inadequacy in food, increase in population, resource depletion

Besides, results also showed that pre-service teachers were not efficient on decoding significance. Only 5 responses can be devoted to this sub-skill. Several examples of responses are:

- People who settled the island use natural resources unconsciously. They act without thinking the consequences of their behaviors.
- There is a limited space, so to grow plants people continuously cut down the trees on the island. Besides they don't plant the new ones instead. The result is increasing environmental problems.

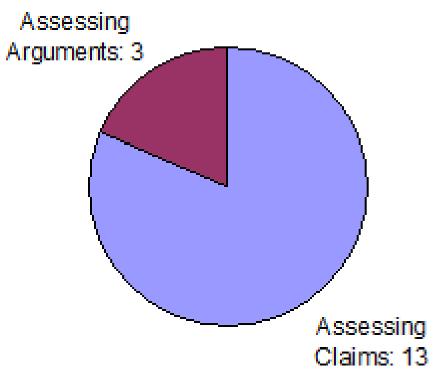
Analysis:



Analysis skill includes three sub-skills; examining ideas, identifying and detecting arguments and analyzing arguments. For the examining sub-skill pre-service teachers were found to be efficient. The results showed that 20 pre-service teachers gave responses that can be attributed to examining ideas sub-skill, 13 of them gave responses appropriate to identifying and detecting arguments and 12 pre-service teachers gave responses that can be categorized in analyzing arguments sub-skill. Several responses for examining ideas sub-skill are given below:

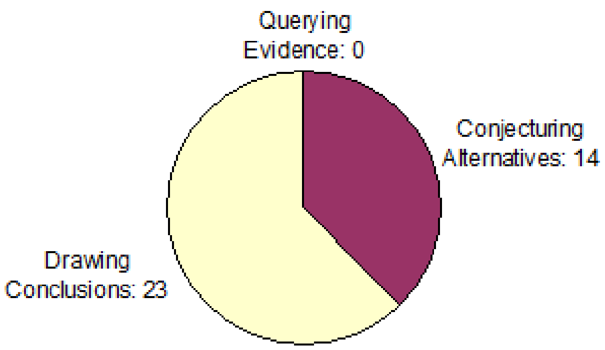
- In Rapa-Nui, people exhausted resources without considering their future. Unconsciously, they did harm to themselves and to their environment. Increasing population and consumption caused a disaster.
- People inhabited the island to escape from war, epidemic diseases etc. Population on the island increases throughout the time. With increasing population and depletion of resources people die of starvation. At last, the civilization on the island ends.

Evaluation:



Assessing the arguments and claims are the two sub-skills belonging to the evaluation skill. Results of the study showed that pre-service teachers do not effectively assess arguments. There are only three representative responses for assessing arguments sub-skill. In one example of response a pre-service teacher stated that “To live in the island, people built houses, they plant potatoes. However, their inconsiderate actions caused the civilization to end.”

Inference:

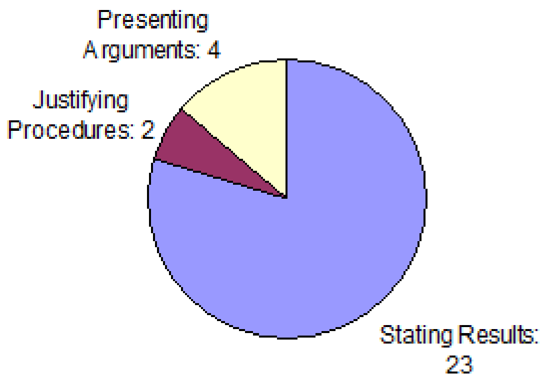


Inference skill consists of subscales of querying evidence, conjecturing alternatives and drawing conclusions. Among these three sub-skills, pre-service teachers were found to be not effective in querying evidence. Besides, they are fairly good in drawing conclusions.

Example replies of pre-service teachers for the drawing conclusion sub-skill are as follows:

- Today, we experience similar environmental problems. The reason for global warming is because of the inconsiderate actions of human beings. The life on the earth will end as occurred in the island.
- Today, similar in the island, we cut down trees and do not plant the new ones. For this reason the structure of the soil changes, and the ecological balance is completely changed.

Explanation:

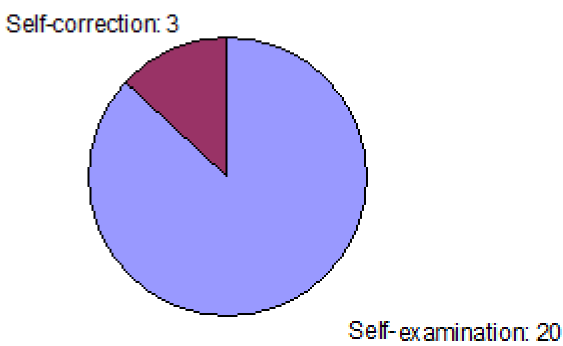


Justifying procedures, presenting arguments and stating results are the three sub-skills grouped under the explanation skill. Although pre-service teachers were found to be effective in stating results, they are not in presenting arguments and in justifying procedures.

Sample representative responses are;

- If we do not act in a planned and systematic way, we will experience the same end *(Justifying procedures)*
- We have to stop environmental degradation, consume resources in a planned way and solve the current environmental problems. *(Presenting arguments)*
- People degraded the food and natural resources in the island. Increase in population caused a competition to get the required sources.*(Stating results)*

Self-regulation:



Self-regulation is the last skill included in critical thinking. Self-correction and self-examination are the two sub-skills grouped under the self-regulation. Results of the study showed that although teachers are effective in self-examination, they are not in self correction.

CONCLUSION

Environmental education is an area in which critical thinking has always been a prior goal (Kyburz- Graber, Wolfensberger & Hofer, 2003). In schools, we expect teachers to teach students critical thinking skills. In order for teachers to be able to implement critical thinking into their classrooms, teachers should be effective critical thinkers. With this respect, it is important to determine pre-service and in-service teachers' critical thinking skills.

The purpose of this study was to determine elementary school science pre-service teachers' critical thinking skills through the story of the Easter Island. Results of the study revealed that most of the pre-service teachers were efficient in categorization, examining ideas, drawing conclusions, stating results and self-examination. Besides, results also showed that most of the participants were not efficient in decoding significance, assessing arguments, justifying procedures, presenting arguments and self-correction.

According to results, it can be concluded that participants are not fully efficient critical thinkers. Based on these results, it can be said that these pre-service teachers will not be effective in applying critical thinking skills in their lessons and cannot teach critical thinking to their students. Considering the results, we have to think over the current teacher education curricula and make urgent revisions on it to improve pre-service teachers' critical thinking skills.

ABSTRACT

Decreasing student performance and difficulties in recruiting students to careers in science have raised questions concerning the quality of science education in Sweden. The government has recognized the seriousness of the situation and has invested significantly in research and development work in order to reverse this trend. The policies pursued points towards an evidence-based reform in science education that seems to conflict with the current educational system. By investigating a set of projects accomplished by the *Evidence-based Practice in Science Education* (EPSE) *Network* in England this paper examines factors of science teaching that require attention in a move towards evidence-based practice. The lessons learned from the EPSE Network are put in relation to the distinction between two ideal perspectives of teaching – the 'Didactical perspective' and the 'Curriculum perspective'. The results indicate that a move towards evidence-based practice requires a 'Curriculum perspective' of teaching and that an evidence-based reform threatens to reduce autonomy, replace professional judgment and prevent deliberations about the overall purpose of science education in Sweden.

Keywords: *Bildung, Didaktik, Evidence-Based Practice, Science Education, Science Teaching*

TOWARDS EVIDENCE-BASED PRACTICE IN SWEDEN

There is a widespread problem within science education regarding decreasing student performance and difficulties in recruiting students to study science. This issue has raised questions about the quality of science education and major discussions on how to reverse this trend (e.g. Osborne et al., 2008). The move towards 'evidence-based practice' (EBP) is considered as a promising way forward for science education in this matter (e.g. Millar, et al., 2006), and governments have been recommended to support an evidence-based reform (OECD, 2003; 2007). Currently in Sweden, this seems to be the case. TIMSS and PISA have indicated that Sweden's position has dropped in the ranking as a result of decreasing achievements over the past 20 years (National Agency of Education, 2009). As a result, the Swedish government has invested significantly in research and development work in science education. 125 million SEK has been assigned to the National Agency for Education to improve the quality of science teaching in schools across the country (Department of Education, 2009a). The Swedish Minister for Education clarifies how this investment is planned to raise standards of achievement (SR, 2009):

> Most teaching is good, even very good, and then it is a question of how to disseminate the good strategies that can be found at some schools to other schools. The National Agency of Education and the Center for Mathematical Sciences in Gothenburg will be responsible for this task. Further, schools that have good strategies will get opportunities to participate in various projects to develop and disseminate them to other schools. (Authors´ translation)

The Swedish government encourages the improvement of science classroom-work in a rather straightforward manner. As such, there are similarities between the government's idea of how 'good teaching strategies' are supposed to result in students´ performances and the leading principle of the evidence-based movement – that is, using strategies of 'what works' (e.g. Slavin, 2002).

In Sweden there has been a growing discontentment with the present line of educational research for not providing a relevant body of knowledge on which teachers and policy-makers can draw (e.g. SOU, 2008:30). Hence, a more explicit push for EBP has been promoted. The Swedish government has proposed to raise the requirements of practical relevance to make clear that the aim of the funded educational research is to '…contribute to a more evidence-based school and preschool' (Department of Education, 2009b, p. 58). A recent official report (SOU, 2009:94) suggests collaboration with the established Danish Clearinghouse founded to conduct systematic reviews of interventions and to provide stakeholders with a source of scientific evidence of 'what works' in education. The Swedish report points out that it may function as a mean to raise '…standards and promote evidence-based practices' in Sweden (Department of Education, 2008, p. 8). To sum up, the Swedish government pursues a line of policy that brings about transformations of both science education practice and research, and that makes it reasonable to expect a move towards EBP (Biesta, 2007; Slavin, 2002).

It should be noted that EBP in education have been developed in different directions that makes different assumptions about the role of research in practice (technical, cultural and critical), the degree of involvement of teachers in research, the nature of teacher professional knowledge and what should count as evidence (ranging from RCT, claimed to be the 'gold standard' in some cases, to include educational research in general). These differences are also reflected in the various terms used to conceptualize different aspects of the EBP movement e.g. 'evidence-informed', 'practice-based evidence', and 'outcome-based education' (Thomas & Pring, 2004). However, as mentioned above, the Swedish government seems to promote a direction of EBP that operates in the 'what works' frame, also known as the 'classical model' of EBP, in which educational research, ideally, should provide teachers with effective and applicable strategies (Hammerslay, 2004; Traianou, 2009). This model assumes that research can and should play a technical role in practice, first of all, to improve the outcomes of teaching (e.g. Elliot, 2001). Henceforth, it is to this 'classical model' that this paper refers in the case of EBP in science education.

This paper examines what to require of science teaching in a move towards EBP in Sweden by investigating a set of projects previously accomplished by the *Evidence-based Practice in Science Education* (EPSE) *Network* in England. The work of EPSE and their use of the term EBP has previously been compared to the 'classical model' (Traianou & Hammersley, 2008) which makes the lessons learned from EPSE a relevant point of departure for an investigation of what might be required of science education in an evidence-based reform in Sweden. This paper argues that the centralized agenda-setting of 'what works' seems to conflict with the current educational system in Sweden since the present curriculum offers teachers a great deal of autonomy to realize the national curricula in the context of their own school and classroom. To illustrate in what way EBP threatens to replace professional judgment of teachers, and prevents wider deliberations of the ends of education, this paper examines the lessons learned from the EPSE Network in relation to the distinction between the 'Didactical' and the 'Curriculum' perspective of teaching (Hopmann, 2007). Potential consequences of an evidence-based reform in science education in Sweden will be discussed.

LESSONS LEARNED FROM THE EPSE NETWORK

The aim of the EPSE Network (part of the *Teaching and Learning Research Programme*) was to explore factors influencing the move of school science towards a more evidence-based practice (Millar et al., 2006). To achieve this, the EPSE Network pursued four interrelated projects and in sum they conclude that…

> …research has a clearer and more valuable role in the design of a teaching intervention, or in generating evidence of the effects of an intervention, if that intervention is relatively short, and has clear learning objectives whose attainment can be measured (ibid., p. 177).

That which the EPSE Network call 'grain size' – the size of the 'units' of teaching and learning in question – is recognized to be of decisive importance for the contribution that research can make in the development of school science. The 'grain size' is considered in a scale ranging from more broader teaching approaches, applicable across subjects, to more specific teaching strategies, focusing on specific learning objectives within a subject domain. The lessons learned from the EPSE projects points out that research in science education can make effective contributions to issues and questions on a more fine grade scale and that researchers, teachers and policy-makers have to think of science teaching and learning 'in terms of smaller, more tightly focused 'units' (ibid, s. 159). If the units are smaller and more focused it might be reasonable to suggest that it is easier to identify clear learning outcomes and appropriate ways of measuring them. The EPSE Network underlines that the pre-specification of curriculum goals in terms of measurable learning outcomes is a prerequisite for determining the efficiency of different science teaching activities. Otherwise it would be quite difficult for research to provide clear and useful evidence of to which extent a particular teaching strategy achieves its intended learning outcome. One of the EPSE Network projects clarifies how valid and reliable measurements can be developed. In an attempt to assess understanding, the team developed a 'measuring-tool' based on '…an operational definition of 'understanding' as the ability to answer a particular question (or set of questions) correctly or to carry out a particular task (or set of tasks) appropriately…' (ibid., p. 165). The results from this project indicate that researchers can provide teachers with useful tools to measure students' understanding, collect evidence of students' learning and clarify learning outcomes in specific subject domains.

Another reason for approaching school science on a finer grade scale is that it brings research on student's understanding of the natural world to the fore. The EPSE network states that '…the importance and value of this research as a resource of improving practice is considerable' (ibid., p. 163). With respect to school science, it might be possible to direct efforts towards specific topics and basic ideas that are recognized as the most conceptually demanding or to pose the greatest difficulties for students. The research on student's understanding is also important in the development of new teaching strategies because it may indicate missing steps and the order in which topics and ideas are introduced. EPSE argues that a well-defined teaching strategy might also facilitate the dissemination as they carry fewer learning objectives, a smaller number of theoretical ideas and have less disturbance on everyday routines.

The lessons learned from the EPSE Network provide insights into what to require of science education in a forthcoming move towards EBP. But it also provides an important opportunity to more closely consider the consequences for the current school system in Sweden.

DIFFERENT PERSPECTIVES OF SCIENCE TEACHING

The move towards a more evidence-based school science requires a perspective of teaching that has close points of similarities with what Hopmann (2007) refers to as the 'Curriculum perspective' (the two different perspectives on teaching presented in this section should be seen as ideal types of teaching to clarify implications of EBP for teachers and teaching). The 'Curriculum perspective' of teaching is, from Hopmann's point of view, about transporting knowledge to students, or put differently, about 'teaching what to learn' (**Figure 1**.).

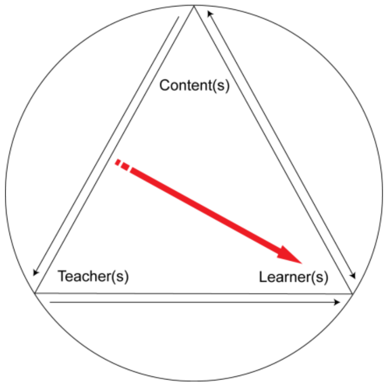

Figure 1. Teaching what to learn

The efforts made by the EPSE Network to improve subject matter teaching and learning requires that schooling is about 'transporting' school science knowledge to students. For instance ... the EPSE network exemplifies how research can contribute to teaching and learning on a more 'fine grade' scale by drawing an analogy with evidence-based medicine. The educational equivalent '…is 'treating' a *specific* knowledge or skills deficit – a lack of understanding of a specific topic or idea, or an inability to carry out a specific procedure…' (ibid., p, 159). The key assumption made by the EPSE Network is that research most likely will render that 'transporting' of knowledge more effective – so that the teaching of X leads, in a rather straightforward manner, to the learning of X – otherwise the hard work of the Network team would be a waste of efforts. This assumption applies even better if school science is considered on a finer grade scale, as exemplified by the EPSE Network analogy with evidence-based medicine. The educational equivalent directs teaching towards specific topics and basic ideas, recognized by the scientific community to be of importance for the development of understanding in each subject. In other words, EBP requires, not only, that teachers should teach what students should learn, but also, that teachers should teach on a specific level and in a specific order – justified by the EPSE Network's view of school science knowledge as…

… hierarchical, with more powerful ideas building upon more fundamental ones, implying an order in which learning can best take place. Science education can, perhaps to a greater extent than some other curriculum subjects, reasonably be seen as a largely goal-directed activity (ibid., p.161).

The ‘Curriculum perspective’ of teaching is a necessity to make room for the ‘key elements’ (specified curriculum goals and appropriate measurements) of EBP. ‘What to learn’ has to be given in order to define it more closely and to set it in measurable terms. The EPSE network’s definition of understanding, as the ability to answer particular questions correctly or to carry out particular tasks appropriately, describes how students’ should master the content in a specific subject domain. It exemplifies how ‘what to learn’ can be more closely framed. A well-defined assignment is a requisite to get hold of the quality of teaching in the ways suggested by the EPSE Network. Teachers can collect evidence of their performance by assessing the distance between student’s achievements and ‘what to learn’ (**Figure 2.**).

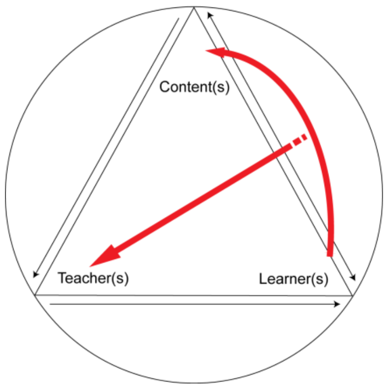

Figure 2. Assessment of distance

An evidence-based school science (drawing on the ‘classical model’ of EBP) requires a ‘Curriculum perspective’ of teaching. This perspective is quite different to the ‘Didactical perspective’, influential in the preparatory work (SOU, 1992:94) of the most recent school reform in Sweden. Differences that is far from surprising, since the perspectives have been developed within different traditions (Westbury et al., 2000). However, these differences leaves us with an interesting comparison that highlights how an evidence-based reform threatens to reduce autonomy, replace professional judgment, and prevent wider deliberations of the overall purpose of science education

According to Hopmann (2007) the common core of the ‘Didactical perspective’ is based on a) a commitment to ‘Bildung’ b) the educative difference of matter and meaning, and c) the autonomy of teaching and learning. A central idea in the concept of ‘Bildung’ is that whatever is learned in the classroom is learned to develop and open up the individuality and the sociability of the student. Science teaching is, from this point of view, not about transporting knowledge from teacher to student, rather it is a about ‘learning by teaching’, where school science knowledge is used as a transformative tool for unfolding the capabilities of the student.

Bildung reminds us that the meeting itself and its outcome are not embedded in the content or given by the teaching, but only emerge on site, then and there where the meeting between a particular student and a particular content happen (ibid, p. 115).

To realize this – 'Bildung' – teaching has to deal with the content in a way which is aware of the educative difference of matter and meaning (**Figure. 3**). The subject matter listed in the curriculum is, of course, without its educative meaning. It arises first in the very act of teaching, in the meeting of teacher, student and content in the classroom (ibid.).

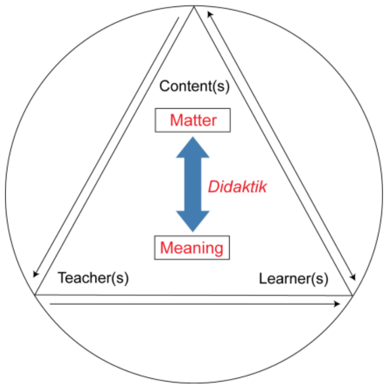

Figure 3. The educative difference of matter and meaning

In the 'Didactical perspective' any given matter can represent several different meanings, and any given meaning can arise from several different matters. This notion is important because it clarifies that the quality of teaching doesn't necessarily depend on student's mastery of the content, nor is the quality possible to be captured by assessing the distance between achievements and intended outcomes. The quality of teaching is more dependent on if and how the educative meaning is opened up for the student, '…if and how it became open in their individual meeting with the content in the given teaching process' (Hopmann, 2007, p. 117).

This difference, of matter and meaning, is absent in the perspective of science teaching required of an evidence-based reform (implemented according to the 'classical model'). If there were a notion of meaning, then meaning would have to be synonymous with the matter, or put differently, one given matter opens up one given meaning, and vice versa. However, in the 'Didactical perspective' of teaching no one can ever, in advance, assure that a meeting of teacher, student and content ends up in reaching the intended meaning.

> What comes out in terms of Bildung is indeed often not visible at all, at least not right away. It depends on what remains after the hurly burly of teaching is done, the battle of minds is lost or won, and the student comes to terms with his or her own world (Hopmann, 2007, p. 11)

This condition – that 'Bildung' never can be taken for granted – is essential in the 'Didactical perspective' and it calls for a great deal of autonomy for both students and teachers. The autonomy is necessary for teachers struggling to unfold certain educative meanings in the meeting of certain students and certain contents. But once in the classroom, one learns that it can always turn out completely differently. If the patterns were given – that is, it is possible to find out 'what works' – the autonomy would be denied and the capabilities of teachers would be reduced to and dependent on their ability to apply certain evidence-based strategies hitting certain pre-specified targets.

CLOSING REFLECTIONS

The move towards EBP in science education has attracted much attention as a promising way to reverse the trend of decreasing student achievement in science education. The corresponding investment of the Swedish government might be seen as a sound initiative to raise standards in science education. However, the lessons learned from the EPSE Network projects highlights that the development of EBP is a major undertaking. It will require a lot of efforts from stakeholders if educational research is to play an important part in the development of evidence-based science teaching and learning in Sweden. Researchers, teachers and policymakers have to adopt a more 'fine grade' view of school science. But also, as illustrated in this paper, the move towards the 'classical model' of EBP demands a 'Curriculum perspective' of teaching that conflicts with the 'Didactical perspective' and the current curriculum in Sweden. This deserves attention because an evidence-based reform will probably involve a fundamental change of the conditions for teachers and teaching, and threatens to reduce autonomy, replace professional judgment, and the wider deliberations of the ends of science education in Sweden. It is important that researchers, teachers and policy-makers in Sweden take this notion into consideration before deciding if an evidence-based reform is worthwhile.

If the potential threats are taken seriously science education in Sweden has to pay more attention to the common core of the 'Didactical perspective' (a commitment to 'Bildung', the educative difference of matter and meaning and the autonomy of teaching and learning) in the development of EBP. The burning question in this paper is whether science teaching and learning should be based on evidence or on a commitment to Bildung? This question is valid when the 'classical model' of EBP is considered, often explicit in the expectations that policymakers hold about what evidence can and should do in relation to educational practice (Biesta, 2007). Other directions within the evidence-based movement that makes different assumptions (e.g. about the role of research in practice, the involvement of teachers in research, the nature of professional knowledge and what should count as evidence) might not require a 'Curriculum perspective' or stand in contrast to the 'Didactical perspective' of teaching. Rather, they might offer a way forward to reclaim the notion of EBP and develop a direction within science education that includes the 'Didactical perspective' of teaching and encourages ongoing deliberations about the overall purpose of schooling. But this is beyond the scoop of the present paper and will be saved for future investigation.

ABSTRACT

Recent studies have shown that teachers need e-learning content that they can easily adapt and reuse for their own purposes. This means that lessons should be made out of small learning blocks or, as they are called, “knowledge objects” / “learning blocks”. A new concept of how to create really useful e-learning content was evolved in Slovenia; namely, by “putting the teacher back into the game”. The selection of proper technologies and tools for managing e-learning content and the establishment of a user-friendly and easy-to-use environment for creating and modifying e-learning content, are essential to ensure basic support and popularization of e-learning.

In this paper, we will present new ideas with proofs of concepts of “modular, really interactive e-content” build on the top of the mathematical, physical, logical and computer-scientific knowledge using open-source solutions, open standards and some programming. E-learning content which will be discussed is not intended to be an electronic teaching book, but the add-on to the standard learning material. You can see some of the results at http://www.nauk.si.

Keywords: *e-learning content, educational content preparation, knowledge extraction, ICT in learning, ICT in science*

INTRODUCTION

In recent years, the process of a creation of electronic educational learning content (e-learning content) in Slovenia has been carried out for the most part with disregard to the teacher; by utilization of a two-way relationship between the authors and the users of the content - the learners (Horvat et al., 2010).

Using experience obtained while leading and cooperating on several EU and Slovenian research projects involving e-learning and e-content creation (Horvat et al., 2007A, 2007B, Lukšič et al., 2007, Božeglav et al., 2009, Horvat et al., 2009), a new concept of how to create really useful e-learning content evolved in Slovenia; namely, by "putting the teacher back into the game".

The manual for teaching employees of the Institute for Interactive Media and Learning University of Technology Sydney (Teaching Matters, 2009) states that one of the important characteristics of a good teacher is if he or she uses the learning materials in a manner best suited to the course, which he or she is currently teaching. Also, a research done in South Korea (Hwang, 2008) on teachers' satisfaction with available e-learning content, gave interesting results. It showed that one of the main factors that affects satisfaction with the e-learning content (and hence its actual use in the classroom) is the possibility that this content can be adapted to the teacher's method of teaching.

By being involved in two projects "Learning Programming" (Lukšič et al., 2009) and "Active Mathematics" (Lokar et al., 2009), which were co-funded by the Ministry of Education and Sports of the Republic of Slovenia, the authors of this paper cooperated in transfering knowledge and experience of preparation and use of e-learning teaching materials (Batagelj et al., 2007 and 2009), acquired over the years, to practice. Specifically, the most important experience was again, that teachers need and want e-learning content that they can easily adapt and reuse for their own purposes.

As the teacher usually serves as an intermediate between teaching materials and the learner, he or she should be able to make all proper choices concerning which content to use and how to combine it into a lesson. This means that lessons should be made out of small learning blocks or, as we will call them, "knowledge objects" or “learning blocks”. In this way, the teacher will be able to change the lesson and promptly adapt the learning process to the situation in the classroom.

In this paper, proofs of concepts of "modular, really interactive e-content" build on the top of the mathematical, physical, logical and computer-scientific knowledge, using open-source solutions, open standards and some programming, will be presented. E-learning content that will be discussed is not intended to be an electronic teaching book, but the add-on to the standard learning material. Some of the examples can already be seen at http://www.nauk.si.

CONCEPTS AND ADVANCED LEARNING BLOCKS

The authors of this paper are members of the NAUK team (NAUK – Advanced learning blocks group, Lokar et al., 2009), which is a group that manages several projects in progress, involved in e-learning content creation. The common aim of NAUK projects is to create a computer-powered system for managing and serving e-learning content that will be extremely suitable for teachers. The main difference between NAUK projects and other software systems for e-learning content creation is in the philosophy supporting the project; namely, instead of the author-learner relation NAUK projects want to introduce the three-way author-teacher-learner relation.

The main idea behind the NAUK concepts is that the teacher will take the teaching materials from the already available online sources, prepared within different content creation projects/systems and, with the help of NAUK system, change and combine them to make a lesson that suits his or her style of teaching and/or the current situation in the classroom. As he or she will be using the resulting content in different situations, the underlying system will offer different ways of export, that conform to the most important up-to-date standards.

Therefore, NAUK project group conceived a concept that would allow combining existing content and with that the creation of one's own learning pathways. With that the project group wanted to tackle, among others, the following widely recognized problems associated with the existing e-learning content:

- it is often realized as a digitized book, without proper interactivity and is multimedia-poor;
- it is linearly structured, although the process of learning is usually not linear;
- it has no contextual dependencies, which are useful while informing the learner about his / her mistakes and the consequences resulting from these errors;
- insufficiently uses new teaching approaches - students will often use the content when a teacher is not present, therefore the concept of multiple interpretation of the same topic is very important, as well as the motivation, progressive building of knowledge, examinations, etc.;
- learners use the same e-learning content several times - some parts of the content should be modified automatically but in such a way that all presentations require the same process of learning (e.g., counting apples is the same as counting rabbits);
- instructions for the teacher are missing - how to present the material, what is the goal or purpose of the content on each step, etc;
- the content is too strongly integrated into the presentation of the material - no revisions and changes are possible (the structure is too monolith);
- there is no real interactivity - the question is not if but how can the augmented reality and other innovative ways be used to improve the learning process.

While observing available e-learning content, group members also found certain shortcomings in prior approaches, mainly through the reactions of the teachers; see also (Prensky, 2001). Although teachers got the opportunity to combine and adapt the learning content, it was quite a difficult task for them. It required non-basic knowledge of managing of virtual learning environments (VLE) and at the same time substantial knowledge of different ICT standards: HTML, CSS, JavaScript, SCORM, etc.

Furthermore, it was a mistake to expect that teachers will only use the materials. They also had didactic and technical comments, since they will be the ones who will teach with the content. However, the biggest surprise has been that the majority of them did not want to create new content, but just to adapt the existing one. Whether this was due to the lack of motivation, the complexity of the process or the poor quality of the available content, it was necessary to find the problems and to fix them.

One thing that has also been neglected in other content creation tools is the process of knowledge extraction. Teachers do not just want some basic quiz type questions but often want to randomize questions, offer feedback for the frequent errors, use structured questions that challenge the learner and therefore make a nonlinear path through the process of examination and teaching/learning. Because each question is a knowledge object, all this will be possible with the use of the NAUK software. Finally, authors of the content have generally been people trained in ICT. If we want teachers with little or no practice to use the software, the software will have to be very intuitive and user-friendly.

The NAUK team also found out that it is not enough to offer only content; it has to be inserted in the appropriate classification system and properly interlinked. A creation of a large repositories of e-learning materials will start a new process; that is, a process of creation of e-learning books that will become a supplement to well-known physical teaching materials. Although physical teaching materials can be used even decades after they are published (printed), this is not the case with e-learning materials. Since e-learning materials are built using different technologies and standards (Varlamis & Apostolakis, 2006), special care should be taken to develop such a process that adapting the presentation of e-learning books to new technologies and standards, in not so distant future, will be possible.

Group members are involved in several projects in progress that are aimed to make e-learning content for: high-school mathematics, primary- and secondary-school physics, elementary-school logic, all pre-faculty levels of computer science classes and faculty-level mathematics. Creating a repository of e-learning content – see Figure 1 – from six different fields of knowledge (at the same time on different levels), promises a greater range of users but also demands a greater responsibility from the group.

The basic idea of NAUK's approach can be easily compared with the popular Lego[4] blocks; see Figure 2-4. The e-learning material should be built by creating: basic / simple building blocks, predesigned e-learning material, which can be later customized, and instructions for preparing customized e-learning material by using simpler building blocks.

When preparing the content, it is important to take into the account its entire life-cycle, which includes the process of creation, use and alteration of the material. The whole process of managing e-learning content is well described in van Assche & Vuorikari, 2006.

Figure 1: The NAUK group portal (NAUK – Advanced learning blocks)[5].

The lack of tools that are easy to use, but at the same time provide the functionality that is needed for quality education, and technical knowledge that is necessary for the implementation of electronic-based education, are the main obstacles today in Slovenia that make the wider use of e-learning in the school environment as well as outside, impossible.

TOOLS FOR E-LEARNING CONTENT CREATION

The selection of proper technologies and tools for managing e-learning content and the establishment of a user-friendly and easy-to-use environment for creating and modifying e-learning content, are essential to ensure basic support and the popularization of e-learning. Of course selecting the technologies and the tools is not a task for the teacher. Creating an environment that will offer quality e-learning creation tools and related services is the goal of the interdisciplinary group of experts with skills from: multimedia, web technologies, web services, user interface design, programming, teaching with the usage of ICT, ect. Such a group was formed in one of NAUK's project named e-SIGMA (Services for building interactive content from mathematics), where they intend to offer technological support to educational material creation process in the context of other NAUK projects.

The main component of the proposed collection of services is the repository of materials, which, unlike the majority of existing systems, is not only intended for archiving and serving content, but at the same time offers the possibility of combining existing materials into new learning units. Sustainability and reusability in light of new technologies of thus created e-learning materials is the main advantage to the existing monolithic presentation of e-learning content that can be currently be seen all over the web. The main scenarios that were envisaged before creating the repository are:

- A teacher constructs a learning path, i.e. a complete learning course for teaching specific topics in the curriculum.
- A teacher that uses a virtual learning environment creates an assessment and imports it into the virtual learning environment.
- A teacher prepares homework with the same content as the teaching material he or she used while teaching, but with different data for every learner.
- A teacher modifies and reuses an already prepared assessment.
- A teacher modifies and reuses an already prepared content.
- A teacher adds interactive elements or descriptions on transitions between elements to already prepared content.
- A teacher uses mathematical notation.

[6] source: http://www.turbosquid.com
[7] source: http://www.track7.org
[8] source: http://www.lego.com

- A teacher comments and grades an already prepared content.
- A teacher contributes his or her own content into the repository.
- A teacher creates new teaching materials or assessments.

Since the process of creation and modification of interactive elements should be as simple as possible, the project group decided to use a similar markup syntax used by the well-known wiki environments, e.g. by Wikipedia[9]. Of course, NAUK's syntax contains additional tags, thereby enabling the addition of various multimedia elements and links between e-learning materials, adding responses to user input, etc. Example of the syntax is shown in Figure 5. In the continuation of the project, the project group intends to offer a graphical editor (powered by AJAX technology[10] - Asynchronous JavaScript and XML) to replace the writing of tags and further simplify the process of e-learning content creation.

By using NAUK services that are currently still in beta version and are intended to become stable in October 2010, the teacher will be able to take existing content from the repository, amend or supplement it, and immediately publish it in the repository. The other important functionality of the repository would be the possibility of exporting the content in the SCORM[11] standard. The teacher will be able to use the e-learning content exported in SCORM in his/her own virtual learning environment (e.g. Moodle, BlackBoard, Dokeos, etc.). Thus, by using NAUK's export service the requirement for technical knowledge of the author (teacher) becomes obsolete.

Therefore, the teacher is no longer obliged to blindly follow the ideas of the original authors of the content, but is able to accommodate the content to his or her needs. He or she can easily:

- take a few questions from existing quizzes (or question banks that store Moodle[12] questions, STACK[13] questions) and build a new quiz,
- add or improve responses (feedbacks) depending on the correctness of the answer to a question or an interactive part of the teaching material,
- take an already built teaching material, remove or replace a certain section, change the order of chapters and slides, etc.,
- correct an animation or add his or her own example,
- build a context aware test from a database of questions, where the the next question displayed depends on the correctness of the answer to the previous question,
- add leaps in a learning pathway and thereby build a non-linear structure.

Figure 5: Example for the wiki-like syntax that is used in NAUK projects to describe e-learning content.

The foundation of NAUK system for e-learning content creation uses GIT[14] distributed version control system that greatly enhances the functionality of service by providing the possibility of:

- comparing differences between versions of the stored e-learning material,
- easing the possibility of modifying the already existing content by starting a new branch, and becoming an author (owner) of a new branch,
- cooperating with other coauthors in writing the same content.

Often overlooked feature needed by repositories of educational content are efficient search engines. Most of current repositories in Slovenia contain "search by the title", some of them also include "search by the content", but almost all of them lack the option to search by other metadata taxonomies: type of materials, their purpose, scope, popularity, level of difficulty, etc. This is precisely the problem of current Slovenian educational network - SIO (Čač et al., 2007), which is being filled with an increasing amount of material but has problems when searching for specific content due to the lack of correct classification. We are therefore forced to review a great deal of content on the same subject to see that some consists only of a single PDF document, others are learning paths, the third kind links to other places on the Internet, etc. This is the reason why eache-learning content in the NAUK repository must be equipped with metadata, which enables the system to classify the materials with regard to different taxonomies: curriculum, content, etc.

Different authors are already making materials in the e-Sigma repository in the context of the projects NAUK. Although the project group is adding new functionalities, the form of the content is largely fixed, which means that teachers do not have to take care of the appearance (representation) of their teaching material, but only of the content, interactivity,

[14] http://git-scm.com/

multimedia add-ons and their place within the learning path of the e-learning material. Example of an exercise can be seen in Figure 5 and its an automatically generated presentation in Figure 6. The presentation is generated automatically when the teacher enters the type of items that he or she wishes to have, e.g. some text, matching question type, hint button with text for the hint and the jump button.

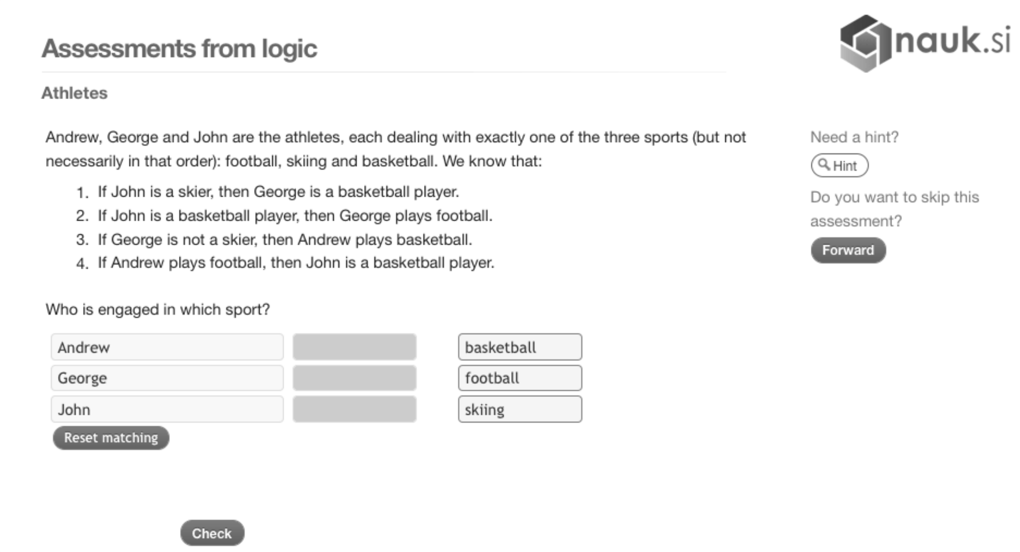

Figure 6: An assessment from logic built automatically by the NAUK system from scenario shown in Figure 5. The learner is supposed to move the correct answers to locations to match sports with players.

Authors can build the content by using the following building blocks: title, subtitle, ..., text, stylized text, table, ordered list, unordered list, link, internal link, button, hint, download, image, video, sound, flash, java applet (Geogebra), gallery, sequence of images, data plot, mathematical notation, virtual book, star map, hotspots, single-choice question, multi-choice question, matching, random-choice exercise, tabbed view, meta data, custom assessments from logic, additional information for teachers, slide menu, etc. The content can be grouped in one, two or three columns that make a slide, slides form sections (with subsections, subsubsections, etc.), sections can be grouped into advanced learning blocks and advanced learning blocks form an e-learning content. The author can choose from different types of slides, e.g. normal slide, popup slide, dragable slide, etc.

Authors can overlay the so-called "tools" above the multimedia content: video, image, plot of the data - measurements, etc. The currently available tools are: angle, distance, vector, vertical lines, horizontal lines, freehand drawing, stop watch, polyline; see Figure 7. By using the tools the author can demand from a learner to "naturally" interact while learning, by solving puzzles, answering quizzes, measuring distances and angles between objects on images or videos, responding to questions by drawing an image or a vector, by constructing a graph, etc.

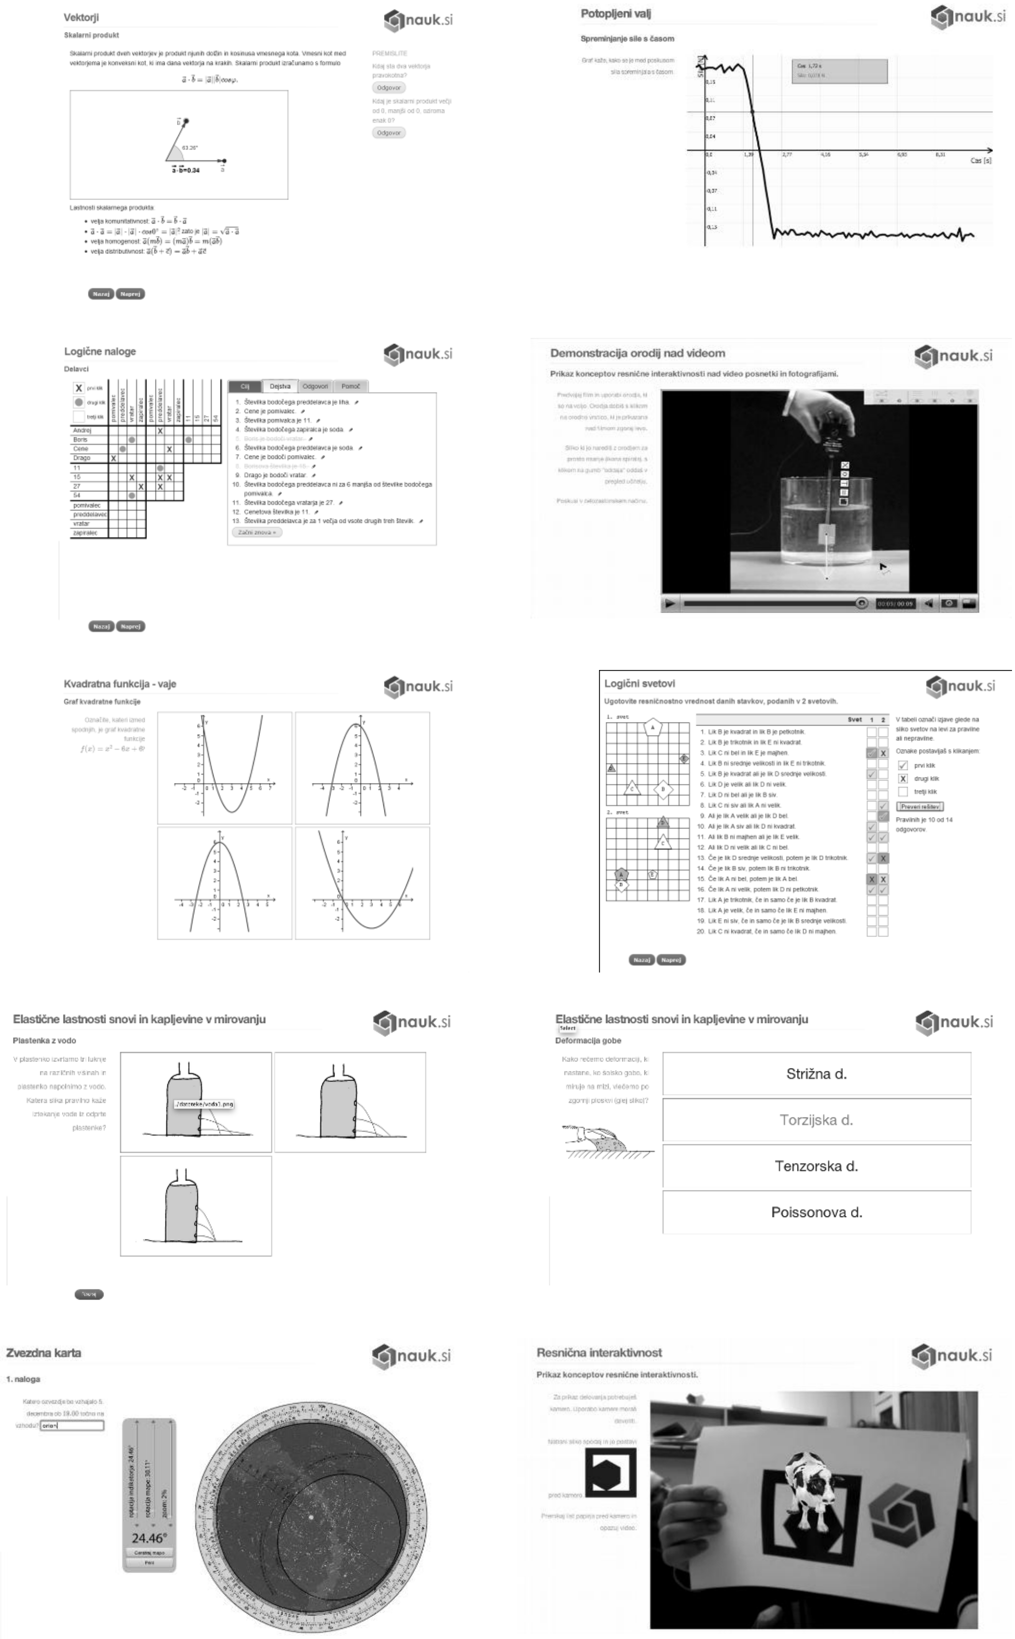

Figure 7: The really interactive learning by using NAUK e-learning tools and concepts.

One of the most important features of the current approach is that every interactive element (quiz element, button and tool) triggers a transition to the next slide, which is selected automatically according to the current context of the learning process. Probably the simplest example of this concept is the following. A learner that makes a mistake by answering a question incorrectly is given a customized response and can be allowed (if this mistake is not too big) to automatically proceed to the next slide, or is returned to another question, which is slightly modified (eased or changed in such a way that the learner will be forced to use the same learning process to solve the modified problem). Thus, the learning path is nonlinear.

FURTHER WORK

Informal interviews with many teachers as well as the first reactions of users have shown that the described concepts and solutions form a good approach that will provide higher quality of teaching and learning. The NAUK project group determined that it is wise to invest further efforts in upgrading demonstrated concepts. Therefore, the project group intends to build a web based community, where it will be possible to give opinions and comments on existing materials and to grade them.

Since good ICT solutions in the field of education spread quickly (Beyond Textbooks, 2009), all members involved in NAUK projects hope for the success of the presented solutions and concepts, but are also aware that further development in this area relies heavily on the satisfaction of the end-users - the students.

ABSTRACT

Living animals are supposed to be very motivating for school pupils. Based on previous results of studies on the effectiveness of educational methods in the field of interest research, we assume that many animal species are suited well for education processes, but there is a surprising lack of empirical studies. Most published work is based on the study of Düker and Tausch (1957) in the 1950s. For this study we developed two treatments with a four-unit experimental class series for fifth and sixth graders (treatment series 1 - living animal, treatment series 2 - film group). Both treatment series just differed in the characteristic “living animal”. We focus on knowledge gain, emotional variables (interest, well-being, boredom, disgust) and experimentation competency. The use of living animals in an experimentally focused class did not necessarily result in an increased knowledge gain; in fact it was lower in the immediate post-test. However, on the long run the differences between the results of the two treatments diminished. Regarding experimental competency both approaches have been effective compared to the control group. Positive emotions (well-being, interest) were higher in the animal treatment, and boredom was lower. We strongly suggest using living animals in the classroom.

Keywords: *biological education; cognitive achievement; experimentation competency, living animals.*

INTRODUCTION

Most educators seem to agree that the use of living animals foster the learning process positively. Nevertheless, there is a lack of theoretical foundation for this acceptance. The few studies published in this field of research show different results. In this study, we focus on the value and the effectiveness of the use of living animals in a middle school classroom. Specifically, we look at the gain in knowledge and in experimentation competency, as well as at emotional variables such as interest, well-being and boredom and disgust. Therefore, we first give a short overview over the theoretical background of the study.

1.1. Theoretical background

The theoretical background of this study is located within the framework of self-determination theory as explicated by Deci and Ryan (1985). These authors identify three basic needs in learning: experiencing competency, autonomy and social relatedness. Educational interventions, therefore, should take these basic findings into account. We therefore based our two different treatments on these suggestions, and developed two alternative educational interventions that both were based onto this theory using hands-on experimental material (Randler & Hulde, 2007).

Emotional aspects of learning

According to Pintrich, Marx and Boyle (1993) learning processes could not barely be defined just as „cold cognition“ and additional factors such as cognitive, affective and social variables have to be taken into consideration, too. Some psychological studies emphasise the significance of emotions in both learning and performance situations. However, until recently, emotions have not been sufficiently attended to in classroom instruction in general (Gläser-Zikuda, Fuß, Laukenmann, Metz & Randler, 2005; Randler, 2009), and have been rather neglected in research in biology education. Hereby, positive emotions were supposed to positively influence learning and achievement processes and negative ones do the contrary (Laukenmann, Bleicher, Fuß, Gläser-Zikuda, Mayring & Rhöneck, 2003; Pekrun, Götz, Titz & Perry, 2002). Our study is based on a concept that distinguishes between current situational emotions and biographically developed and enduring "trait"- emotions (Randler & Bogner, 2007; Ulrich & Mayring 1992). In the focus of this present study were the situational ("state") emotions because they could be directly linked to the content of the respective educational unit and the respective tests on achievement. The concept of "state"-variables means that pupils responded immediately after the respective lessons.

Cognitive achievement in animal classes

In nearly every text book on biology teaching, the worth and value of living animals in the classroom is unquestioned, however, this far-reaching conclusions have been only rarely under thorough study and this assumption becomes less valid if empirical evidence is required. There is a surprising lack of empirical studies currently dealing with the effects of living animals on learning outcomes and most of the published work, especially during the 1960ies until the 1980ies is based on a flawed methodological design. Most of these suggestions are based on the pioneering work of Düker and Tausch (1957) in the 1950ies. In more recent work, e.g. Morgan (1992) found an interaction between the level of involvement (which could be considered as some kind of measure of motivation) and learning outcome in a treatment based on snakes. That is, the more direct contact with the snakes existed, the lower was the retention and learning outcome. Sherwood, Rallis and Stone (1989) found no differences in learning outcome between living insects and preserved specimen during an exhibition at a zoo, but these authors revealed differences in affective variables where living animals were assessed as more motivating by the pupils. Killermann (1996) reported a higher cognitive achievement when using living animals in secondary school pupils by comparing living invertebrates with slide presentation. In primary school pupils, Randler, Ilg and Kern (2005) showed a higher learning and retention effect when pupils who participated in lessons about amphibian species also encountered these species in a natural setting during migration, while differences in interest, well-being, boredom and anxiety did not exist between the indoor and outdoor group.

Experimentation competency

Recently, effort has been put into the measurement of competency, especially with a focus on experimentation (Neber & Anton, 2008; Phan, 2008). In particular, the focus lies on the competencies of forming hypotheses, planning experiments and analysing data. These competencies were selected because they are crucial to experimentation as problem solving, according to the SDDS model (Klahr, 2000; Hammann, Phan, Ehmer & Grimm, 2008).

MATERIALS AND METHODS

The study took place in the second half of the school year in 2009. 516 pupils (244 boys and 272 girls) from middle schools participated in this study (living animal-group: n=225; film-group: n=172; control-group: n=119). Pupils were 5th and 6th graders (10 to 13 years). The

German school system in Baden-Württemberg separates pupils at the end of the 4th grade into three different stratifications according to their cognitive abilities. In our study, pupils from the highest stratification (in German "Gymnasium"), and from the middle stratification (in German "Realschule") participated in this study.

Treatments

We developed four different treatments aimed at enhancing experimentation competency and cognitive achievement. Treatment 1-3 (mouse, woodlice, and snail) differed between the treatment groups while the fourth treatment was identical (Figure 1). Therefore, it served as a kind of internal control to assess whether both treatment groups are indeed comparable. The fourth unit had no influence on the experimentation competency measure and the post- and follow-up test (see Procedure for details). In all treatments, pupils worked together in groups of 3-4 and made observations on their own. Therefore, a detailed booklet was developed guiding the pupils through their learning process. In the living animal treatment, pupils carried out all experiments on their own, while in the film treatment, the pupils watched a film especially designed for this unit. For example, in the mouse treatment, pupils observe a house mouse (*Mus musculus f. domesticus*) in an open field test. There are three jobs to do: one pupil is keeping the time, another one is observing the mouse and every five seconds reports the exact position on the field, while the third pupil notes the results on a sheet. After some time, the positions are changes so that every pupil experiences all of the three jobs. The difference between the treatments is simply the presence of a mouse. In the living animal treatment, the pupils observe the living mouse, in the film treatment, the pupils observe a mouse on a film (without any commentaries), so the situation is nearly identical and the pedagogical preconditions (group-based, hands-on work) are similar. We feel that is a rather strict experimental approach reaching farther beyond most previous approaches tackling this question. The fourth unit is concerned with bird flight and contains hands-on experiments. We have included this fourth unit, because we suppose that both treatment groups should score equally to the identical educational treatment (bird flight), which, in turn, provides evidence for the fact that both treatment groups are comparable.

To minimize the influence of the teachers, they got detailed instructions for the implementation of each lesson. In addition, the students got a multi-page workbook for each unit to ensure an additional and largely self-directed process. The workbooks are nearly the same in both groups (experimental and control), and differed only in the instructions for the experimental procedure. Everything else was equal: the instructions for

a) the identification phase of the hypotheses, for the experimental planning
b) the analysis and interpretation of data
c) general guidance on the conduct of an experiment (e.g., control of variables, varying one factor, the role of an control-experiment)
d) the observation of animal's external features, which were performed in advance of the experiment to accustom the students to the animals and to show how they have to deal with them.

The initial problems (inquiry-based of each lesson) were illustrated on slides, which were identical in both groups, too.

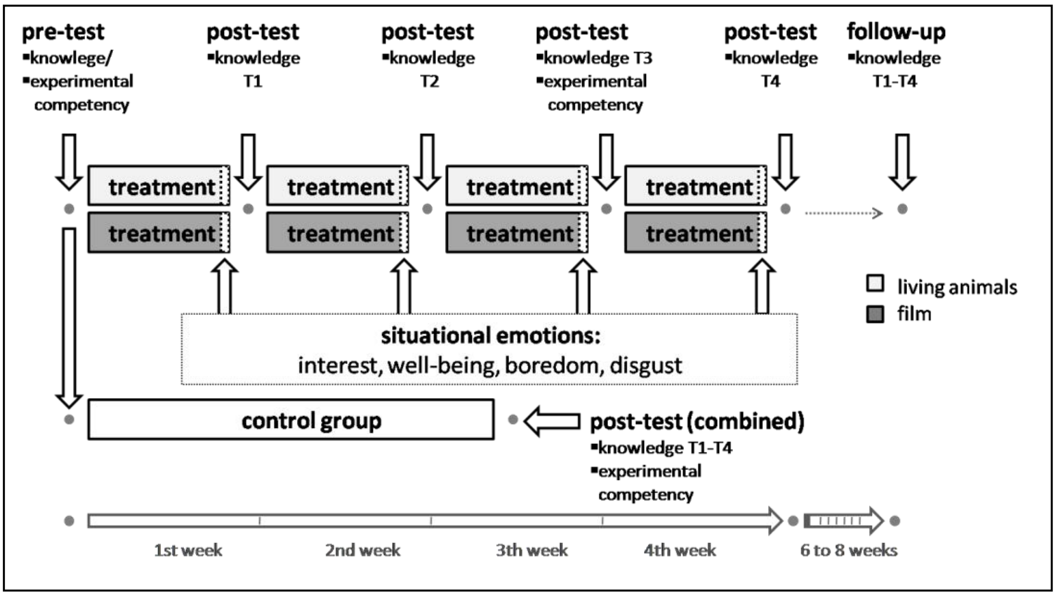

Fig. 1. Overview over the experimentation procedure, the measurements, and the treatment and control groups.

Measurements

We used a battery of tests to assess the different constructs of our work (Figure 1). Experimentation competency was measured using a paper and pencil test (Cronbach's alpha = 0.619; 27 Items) Cognitive achievement was measured using a pre-/post-test and follow-up test design, also based on paper-pencil-tests. Situational emotions were assessed immediately after the respective treatment units. Here, we used a short scale that measured the constructs interest, well-being, and boredom (Randler, 2009) and a one-item measure of disgust. In addition, the students were asked the following teaching relevant questions (Mixed methodology; Mayring et. al. 2007)

1. What did you like best about the lesson?
2. What did you dislike about the lesson?
3. What is of interest to you, right now?

Procedure

To prevent order effects, the treatments were distributed at random, i.e. one class started with woodlice, another with snails, and the third with the mouse unit. Every week, one treatment was applied. The bird flight unit was always used as fourth unit because it served as some kind of control. This balanced design ensures that there are no order effects of the treatments. Experimentation competency and pre-test were carried out before the educational unit started in all three treatment groups (control group, living animal group, film group). After every unit (mouse, woodlice, snail, bird flight), we assessed the situational emotions and after one day up to one week, we assessed the cognitive achievement in the treatment groups. In the control group, post-tests were combined because the pupils received not educational intervention. The termination of the post-test reflected the fourth treatment post-test. After the three first treatments (which were randomized to achieve a balanced design), and before the bird flight unit started, we again assessed experimentation competency in both treatments. The follow-up test was written with a delay of six to eight weeks in both treatment groups.

Statistical analyses

We used a series of general linear models (GLM) to calculate the effects of gender and treatment (and the interaction term between both) by using prior knowledge as a covariate to account for individual differences in prior knowledge. The calculations were carried out in different ways: first, we compared the treatment group (film/living animals) versus our control group, and second, we compared both treatments (film vs. living animals) with each other. Experimentation competency was compared without any transformation of the data, while the cognitive achievement tests were z-scored to account for differences in the respective tests. We assessed knowledge by immediate post-tests in the four units, woodlice, snail, mouse and bird flight. Each of these four immediate post-tests was z-transformed to achieve a mean of 0 and a standard deviation of 1. Afterwards, the post-test scores of woodlice, snail and mouse were added to get an overall post-test score with an equal weighting of every unit. In the follow-up test, the procedure was similar. The bird flight unit was compared separately because it was identical in both treatments to serve as some kind of control. For the comparison of the emotional values we used a T-test.

Out of the responses of the qualitative survey we formed different higher level structures according to Mayring 2000 and converted them into values to facilitate a mixed methodologies approach (Mayring 2001). For the calculation we used the Chi-square-test (X^2-test).

RESULTS

First, we found differences between the treatment and the control group in experimentation competency, suggesting that both treatments (living animals/film) increased the competency (see Figure 2). Pre-treatment experimental competency had an expected significant influence on post-treatment experimental competency ($F_{1,460}$=87.574, p<0.001, partial η^2=0.16). Gender also revealed a significant influence with girls achieving a higher experimental competency (F=$_{1,460}$=17.609, p<0.001, partial η^2=0.03). Finally, treatment vs. control showed a significant influence ($F_{1,460}$=30.716, p<0.001, partial η^2=0.06). However, there were no differences between the two treatments, i.e. living animals as well as films both could be used to increase experimentation competency.

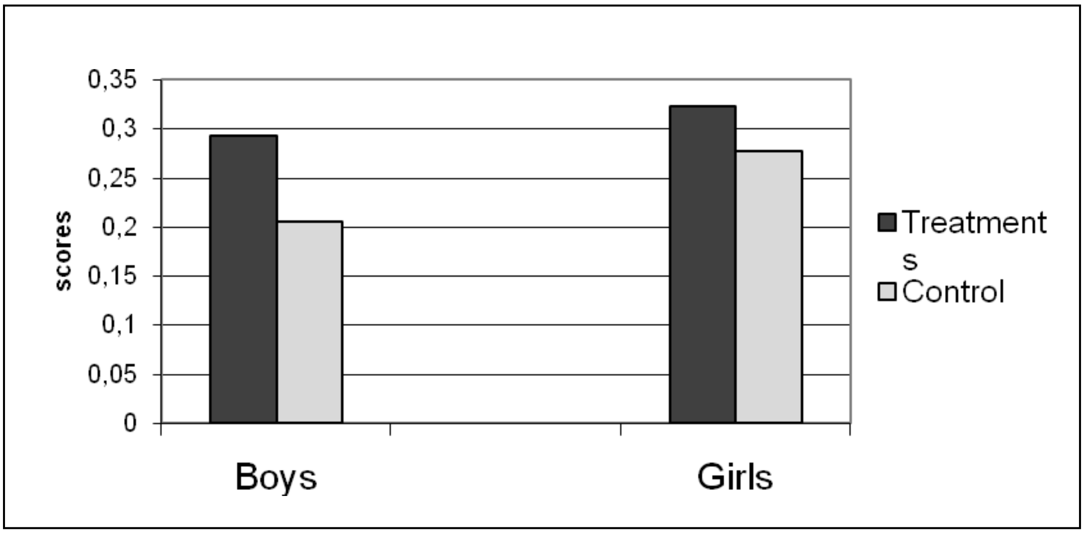

Figure 2. Comparison of experimentation competency of both treatments with the control group, estimated marginal means from a GLM using pre-experimentation competency as co-variate.

Second, there was a significant difference and a high effect size of this difference when comparing cognitive achievement between the treatments and the control group. The pupils acquired a substantial knowledge in the post-test compared to a group without treatment. Pre-treatment knowledge had an expected significant influence on post-treatment knowledge

($F_{1,486}$=72.538, p<0.001, partial η^2=0.13). Treatment vs. control also showed a significant influence with a high effect size ($F_{1,486}$=797.893, p<0.001, partial η^2=0.62).

However, there was a significant difference between both treatments and a gender effect based on a multivariate GLM. Thus, the film group acquired a significantly higher knowledge than the group with living animals (Wilk's λ=0.942, F=10.76, p<0.001, partial η^2=0.05). Further, girls seem to learn better than boys (gender: Wilk's λ =0.959, F=7.524, p=0.001, partial η^2=0.04), while the interaction was not significant. As expected, the pre-test scores also had a significant influence (Wilk's λ =0.850, F=30.645, p<0.001, partial η^2=0.15). Table 1 depicts the subsequent univariate GLMs (see also Figure 3). The difference between the treatments was lower in retention test, as was the effect size (see Table 1).

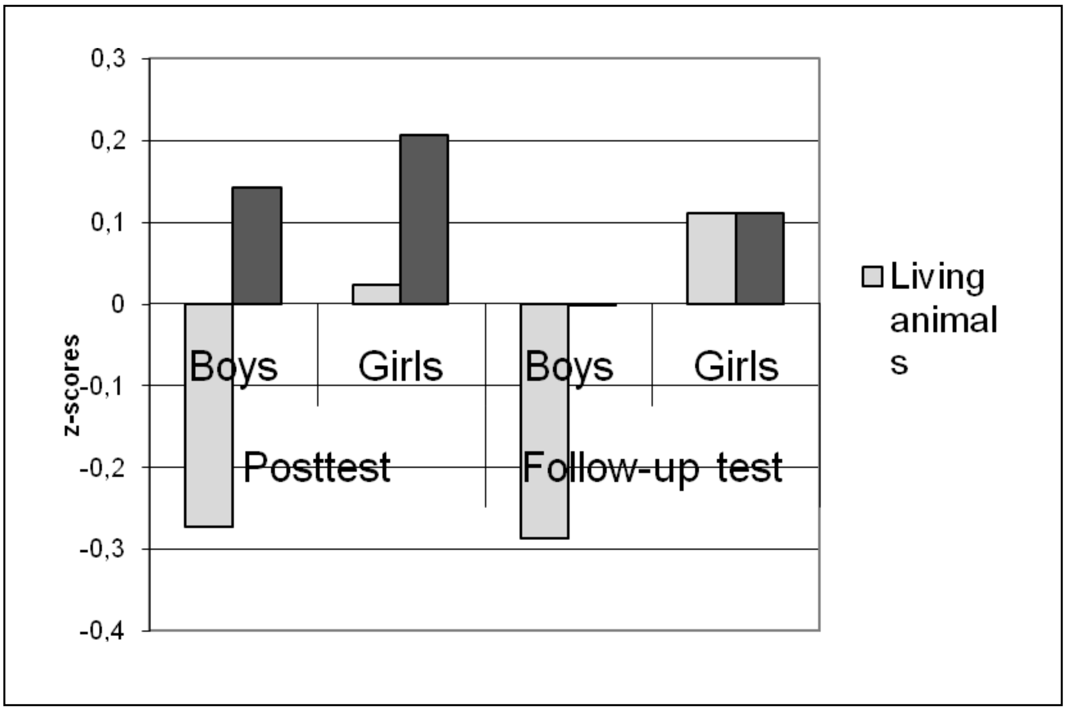

Figure 3. Comparison of the cognitive achievement in both treatments.

In detail, there were no differences between both treatments in the woodlice group, but pupils performed better in the film group, both in the unit snails (Wilks' λ =0.974, F=4.451, p=0.012, η^2=0.02) and mouse (Wilks' λ =0.958, F=7.420[a], p=0.001, η^2=0.04).

As expected, both groups scored equally in the bird flight unit (Wilk's λ = 0.997, F=0.441, p=0.644, η^2=0.00), which was similar in both treatments, and, therefore, shows that both treatment groups are comparable.

Third, we found differences in the emotional variables interest, well-being and boredom (Figure 4). Pupils in the living animal treatment scored interest and well-being significantly higher and boredom significantly lower than pupils from the film treatment.

Table 1. Univariate GLMs using post-test or follow-up test as dependent variable, gender, treatment as fixed factors, and pre-test scores as co-variate.

Source of variation	Dependent variable	Type III sum of squares	df	Mean of squares	F	P	Partial η^2
Corrected Model	Posttest	33.330[a]	4	8.332	23.191	.000	.210
	Follow-up	20.281[b]	4	5.070	12.544	.000	.126
Konstanter Term	Posttest	.266	1	.266	.740	.390	.002
	Follow-up	.077	1	.077	.191	.663	.001
Pretest	Posttest	21.524	1	21.524	59.904	.000	.146
	Follow-up	9.728	1	9.728	24.068	.000	.065
Gender	Posttest	2.789	1	2.789	7.762	.006	.022
	Follow-up	5.621	1	5.621	13.908	.000	.038
Treatment (film vs. living animals)	Posttest	7.738	1	7.738	21.536	.000	.058
	Follow-up	1.780	1	1.780	4.403	.037	.012
Interaction gender * treatment	Posttest	1.159	1	1.159	3.227	.073	.009
	Follow-up	1.772	1	1.772	4.384	.037	.012
Error	Posttest	125.397	349	.359			
	Follow-up	141.061	349	.404			
Total	Posttest	158.800	354				
	Follow-up	161.416	354				
Corrected total variation	Posttest	158.727	353				
	Follow-up	161.342	353				

[a]. R^2 = .210 (corrected R^2= .201)

[b]. R^2 = .126 (corrected R^2 = .116)

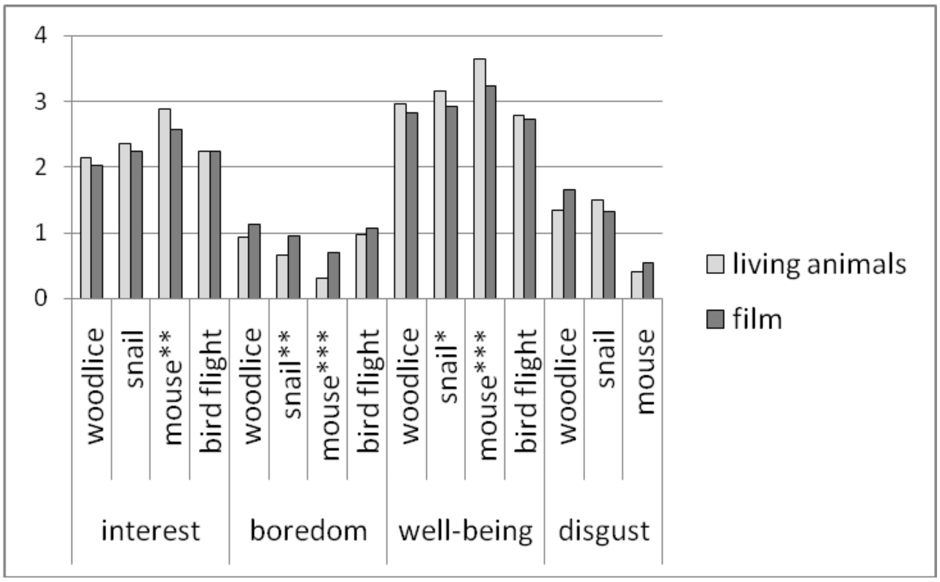

Fig. 4. Comparison of two different treatments in emotional variables. *p<0.05, **p<0.01, ***p<0.001. Scale from 0 – 4.

Fourth, we found negative correlations between boredom and disgust and the cognitive achievement tests. Pupils experiencing higher boredom and higher disgust scored significantly lower in the post-test and the follow-up test (boredom and post-test r=-0.100, p=0.047; boredom and follow-up test: r=-0.115 p=0.028; disgust and post-test r=-0.103, p=0.043; disgust and follow-up test: r=-0.111, p=0.033).

Fifth, the results of the qualitative part of the survey could largely confirm the findings of the paper and pencil test. On the basis of this qualitative approach, it has also been shown, that the pupils of the living animal group more frequently mentioned animal specific fields of interests beyond the contents of the lesson, like living conditions, habitat or way of life (snail: p<.000; mouse: p<.000; woodlice n.s.; Figure 5; table 2).

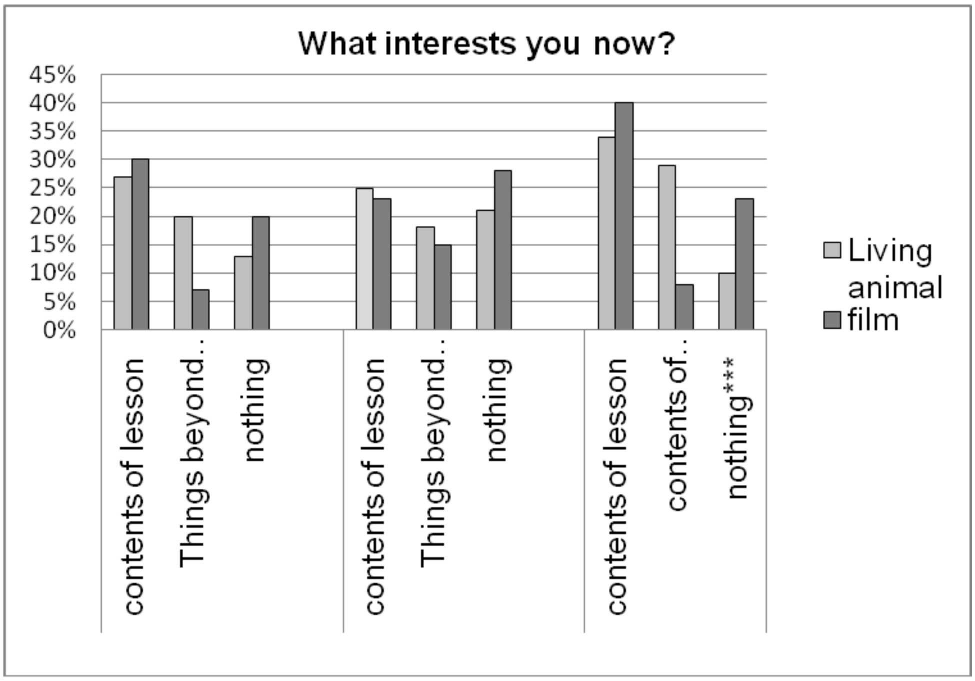

Figure 5. Qualitative approach - differences between the pupils animal specific interests after the lesson.

Table 2. Animal specific fields of interests after the lesson

Snail	Mouse	Woodlice
Way of life***	Way of life **	habitat*
Reproduction and offspring	Maximum age **	Reproduction and offspring**
	Reproduction and offspring*	

DISCUSSION

The results of our study are encouraging since they show that the use of living animals in the classroom is of benefit for the pupils. The experimental treatments both enhanced the experimentation competency, a fact, that has been rarely demonstrated in any other study in biological education. In fact, we are currently only at the start of measuring competencies in field studies (see, e. g. Hammann *et al*., 2008). Therefore it is necessary to develop these measurement instruments further. Nevertheless, our results are encouraging since they show that it is possible to increase experimentation competency at all, albeit effect sizes were low. As we used a control group filling in the same questionnaires, and this group scored lower, we can assure that the increase in experimentation competency is not an artifact or a result of repeated testing but a significant treatment effect. As both treatments produced a similar effect in experimentation competency, we concluded that both educational treatments are equally suited for lessons with the aim to increase this competency.

Cognitive achievement, however, was better in the film treatment, suggesting that some factors may detract pupils from learning. In the end, however, the difference between both treatment groups diminished. Pupils may be irrigated by the living animals that may evoke disgust (in a negative manner) or interest in a positive manner. Also, handling animals might be more difficult than just watching videos. This could be – at least partially – be explained by the cognitive load theory (Sweller, van Merrienboer & Paas, 1998). Pupils in the treatment with living animals were confronted with new learning objects (animals) and they are not prepared to this new task, which, in turn, has an effect on learning and retention. So it might be easier for pupils to focus on the tasks in the film group. Nevertheless, we used the same educational methods (group-based learning) in both treatments, and both groups had to work on their own, and both did the same kind of analyses using similar working sheets. Therefore, the differences should be clearly ascribed to the variable living animals. Nevertheless there are some points strongly argue for the use of living animals in lessons. The values of the emotional variables were largely higher in the living animal group. It has also been shown, that the pupils of the living animal group more frequently developed further animal specific questions beyond the contents of the lesson. An important aim of biological education. Moreover, in the follow-up tests after 6 to 8 weeks the differences in the subject specific knowledge between the two groups were slightly lower than in the post-test. Here it would be interesting to measure again after a longer period. Perhaps the differences between both groups would be completely balanced.

Our study has some strength that should be emphasized: First, we used an additional intra-individual control group, the bird flight treatment that was similar in both treatment groups. As both treatment groups achieved similar cognitive scores and scored the emotions also similar, we concluded that there were no differences between both treatment groups. Of course, the person of the teacher may have an significant influence on learning and retention, we can exclude such effects because of the high sample size. Also, Randler and Bogner (2008, 2009) showed that typical treatment-control group comparisons with different teachers might as good as related groups based on a similar teacher. Second, we used a sophisticated design to account for order effects. Assume, for example, that one of the three specific treatments would be best to be placed at the beginning or the end of the intervention;

this might have caused all the effects. As we did not find any order effects in our treatments, we can exclude these effects.

CONCLUSION

The results of this study are encouraging in different ways. First, we found no differences in experimentation competency between both treatments, clearly suggesting that living animals can be used in such educational units because they evoke positive emotions. Further, living animals show a positive emotional effect. It is likely that the students using living animals develop more questions that go beyond the contents of the lesson. To substantiate this finding more research is needed. In this case, investigating the effects of other species would be interesting.

Although the cognitive achievement was lower in the living animal group, we suggest that the higher emotional values, the development of further questions and also the reduction in cognitive content should be taken as an advantage to use animals in the classroom.

EDUCATIONAL REFORMS AS PARADIGM SHIFTS: UTILIZING KUHNIAN LENSES TO UNDERSTAND TEACHER RESISTANCE TO EDUCATIONAL REFORM

ABSTRACT

Research acknowledges that reform efforts in education often face with a resistance, particularly on the part of teachers. This study attempts to get to a better understanding of the reasons of resistance to change on the teachers' side through utilizing the structure of scientific revolutions as described by Thomas Kuhn as an analogy. To this end, a recent curriculum reform in science education in Turkey is taken as a case and the previous and new biology curricula are analyzed comparing their emphasis, approaches to the nature of scientific knowledge, theories of learning, models for teaching and approaches to the assessment of learning. This analysis revealed that the curriculum reform experienced in Turkey has introduced a new world for teachers, which is fundamentally different from the previous one. To this end, the study discusses that understanding and applying the new paradigm introduced by the new curriculum could be one of the major barriers that teachers face in the implementation of the curriculum reform.

Keywords: *Educational reform, paradigm shift, teacher resistance*

INTRODUCTION

The main aim of any reform in education is to improve educational programs and practices which will, in turn, assist to meet overall objectives of education in more effective ways (Fullan, 1991). Change is a difficult process, because, educational change of any significance involves changes in organizational structures, communications, resource allocation, practices, and beliefs and attitudes (Avenstrup, 2007). Research acknowledges that reform efforts often face with a resistance, particularly on the part of teaching staff. Current literature on educational research usually attributes to external factors such as entrance examinations at different levels of education, parental pressure and top-down nature of reforms (Könings, Brand-Gruel, & Van Merrienboer, 2007; Wendy, 1991) and internal factors such as lack of training (Könings, Brand-Gruwel, & Van Merrienboer, 2007), leadership (Roehrig, Kruse &, Kernl, 2007) and communication (Wendy, 1991) as sources of the resistance to change on the teachers' side. Although this categorization of the sources of resistance to educational change on teachers' side is important and helpful in understanding the dynamics of educational change, multiple perspectives is needed to capture the nature and aspects of this complexity (Anderson, & Helms, 2001; Schmidt & White, 2004).

In this study, we assumed that the nature of scientific revolutions as described by Thomas Kuhn provides one of the possible ways to analyze the nature of large-scale educational reforms and the complexity of the process. Further, we believe that using such an analogy, we could get to a better understanding of the reasons of resistance to change on the teachers' side. Briefly, Kuhn describes progress in science in terms of paradigmatic shift. One important aspect of Kuhn's paradigms is that the paradigms are incommensurable—that is, it is not possible to understand one paradigm through the conceptual framework and terminology of another rival paradigm. In other words, rival paradigms describe different worlds. The related question here is that what happens to a scientist that has experienced a paradigm shift in the field? According to Kuhn, when the “normal scientist” is confronted with evidence that the new paradigm may be mistaken, he or she tends to ignore that evidence and sticks with it. There may be many reasons for this conservatism, being educated in the new paradigm, having established themselves in it, perceived difficulty of learning a new conceptual framework, etc. This conservatism is exactly what we utilized in our study.

In one sense, large-scale educational reforms resemble scientific revolutions. As in paradigm shifts, large scale educational reforms bring new conceptual frameworks, introduce new educational aims and view on how people learn, require to adopt new teaching and assessment approaches and materials, etc. It is expected from the implementers of the reform, that is teaching staff, to comprehend and reflect the new requirements of the reform in their practice. However, this is not an easy task. Many teachers were educated with the conceptual framework and norms of the previous educational approach, as the normal scientist working in the old paradigm did before the paradigm shift in Kuhn’s scientific revolutions. We assume that it is difficult for or cannot be expected from a practicing teacher, as for the normal scientist experiencing a paradigm shift, to comprehend and adopt himself/herself to the new world that is introduced by the educational reform.

With this conceptual framework and in order to exemplify how a large scale educational reform introduces a new world for teachers, this study analyzed a curriculum reform recently taken place in secondary biology education in Turkey. The curriculum is the heart of education and all else in the system is derived from this: how learners should be assessed, how teachers should be trained and develop, what textbooks and other learning support materials should be like, how schools and the educational system should be organized and managed, and the allocation of resources necessary for the system (Avenstrup, 2007).

Turkey has one of the biggest and youngest populations in Europe; therefore, education has been and continues to be of critical importance to the nation’s social, political and economic development. Like many governments around the world, the Turkish government is aware of the importance of preparing its citizens for the challenges of the new century, and has introduced many reforms at various levels of education in the last ten years. The latest of these reform efforts took place in the secondary education. With this movement, both the structure and content of the secondary education was targeted. The length of the secondary education, which was three years, has become four years. The content and philosophy of secondary education has also targeted. In secondary science, for example, new science curricula and curriculum materials have been introduced. This new curricula have presented new aims, learning and teaching approach, and method of assessment for secondary science teaching.

METHODOLOGICAL AND ANALYTICAL FRAMEWORK

A qualitative oriented approach was employed and Ethnographic Content Analysis (ECA) (Altheide, 1996) was chosen as an appropriate methodological framework for this particular research. In this framework, the method of reviewing started with reading and coding previous and new biology curricula in the light of previously determined themes (curriculum emphasis, assessment approach, etc.). However, new themes were included as they emerged in this constant comparison of documents (for example, the nature of scientific knowledge).

RESULTS

The analysis of the two biology curricula was conducted by comparing the approaches of these documents to five major themes. These were the *curriculum's emphasis*, *the nature of scientific knowledge* depicted in the curriculum, the *theory of learning* that the curriculum utilizes, *model of teaching* that the curriculum suggests and, the curriculum's approach to *the assessment of learning.* Analyses conducted in these five themes revealed major differences in the approaches of the two curricula.

Curriculum Emphasis

One of the important steps in curriculum development process is the identification of coherent set of messages to the student about science (Roberts, 1982). Because, Roberts argues, such messages *'constitute objectives which go beyond learning the facts, principles, laws, and theories of the subject matter itself – objectives which provide answers to the student question: "Why am I learning this?"'* (p. 245). This answer to this question reflects the emphasis on what is valued and desired in the curriculum. Roberts calls this '*curriculum emphasis*' and, discusses and describes seven different emphases utilized by curriculum developers in the last century. He argues that each emphasis, naturally, shapes the content and the structure of the curriculum.

The framework and classification defined by Roberts was used in analysing the differences regarding the emphases of both curricula. To this end, the overall objective of the previous biology curriculum emerged as;

'... to help individuals who will constitute the science-society to acquire scientific problem solving skills for the problems they may encounter in their everyday life ...' (Ministry of National Education [MNE], 1998, p.131).

This overall objective was followed by a list of attainment targets. *'Learning the general structure of living things'* was, somewhat inconsistent with the overall objective, on the top of the list. This was followed by '*learning about and caring environment'* and *'developing habits needed for a healthy life'.* Parallel to these attainment targets, the previous curriculum put emphasis on the learning of biology content and developing skills to solve everyday problems utilizing a scientific approach**.**

In light of this analysis, the previous curriculum's approach falls into the *'Correct Explanations'* and the *'Everyday Coping'* emphasis in Roberts's (1982) framework. Roberts argues that the *Correct Explanations* emphasis stresses science products that are accepted by scientific community. This emphasis gives the messages *'master now, question later'* (Ibid.). The *Everyday Coping* emphasis, on the other hand, declares that science is an important means for understanding and controlling one's environment (Ibid).

The overall objective, or the 'vision' as it is called, of the new curriculum is stated as;

’... to educate scientifically literate individuals that understand the nature of science… appreciate the necessity of learning biology… possess adequate cognitive conceptual frameworks regarding biological concepts… comprehend the relationship between science-society-technology… approach problems with the principles of scientific inquiry.’ (MNE, 2007, p.3).

The structure and content of the new curriculum were shaped in order to achieve the overall objective. To this end, the new curriculum targets developing skills and attitudes related to the aforementioned overall objective (that is educating scientifically literate citizens) as well as developing knowledge of biology. The attainment targets are divided into three groups in the new curriculum. These are; a) *Science-Technology-Society-Environment,* b) *Communication Skills, Attitudes and Values*, c) *Scientific Inquiry and Science Process Skills*.

Considering such an overall objective and related attainment targets, the new curriculum’s emphasis bears the aspects of three emphases in Roberts’s (1982) classification. These are the *‘Structure of Science*’ emphasis, the *‘Science, Technology, and Decisions’* emphasis and, the *‘Scientific Skill Development’* emphasis.

The new curriculum’s emphasis includes the ‘Structure of Science’ emphasis as it stresses and gives messages about how science functions intellectually in its growth and development (Roberts, 1982). The new curriculum targets student understanding on the nature and status of scientific knowledge, the interplay between evidence and theory, the role of models for explaining natural phenomena, the subjective nature of science, etc. Unlike the previous curriculum’s emphasis on ‘Everyday Coping’, the new curriculum puts an emphasis on the limits of science in coping with practical affairs. The new curriculum also stresses the development of scientific process skills as opposed to learning the products or content of science, which were emphasized in the previous curriculum.

To conclude, as discussed above, the two biology curricula have radically different emphases regarding the objective of biology education at secondary level. This difference in the emphases shows that these two curricula have different worldviews. Consistent with their difference in worldviews, analysis revealed that the curricula also have different understandings about the nature of science and scientific knowledge.

NATURE OF SCIENTIFIC KNOWLEDGE

The analysis revealed that the previous and new biology curricula have radically different perspectives with regard to their perceptions of the nature of scientific knowledge. While the previous biology curriculum presented the nature of knowledge from a positivist perspective, the new curriculum presents a constructivist perspective. Science, for example, was defined as *‘cumulative knowledge gathered through observations and experiments’* (MNE, 1998, p.139) in the previous biology curriculum. What is immediately evident from this description is an introduction of science as “body of knowledge”. The view that science represents a body of knowledge was implicitly supported in the following units by portraying biology as a collection of facts. For example in the unit titled *Views about the Origins of Life* in which the theory of evolution was introduced, the curriculum stated that

‘... the factual knowledge in biology was presented in the earlier sections, this section, however, presents interpretations of these.’ (MNE, 1998, p.211).

Such a description of science and scientific knowledge also underpinned another view that there is an existing truth or reality out there and science represents the way of reaching that reality or truth. This view portrayed science as a process of discovering (or collecting, exploring) what is out there. The previous curriculum presented this process as “the” scientific method. The scientific method, according to the previous curriculum, was a step-wise and universal procedure in science. The previous curriculum’s expectations from the students were;

- *Write and/or articulate the steps of the scientific method.*
- *Decide whether the steps of the scientific method were used in a given example of a scientific investigation.*
- *Write and/or articulate that it is required to follow the steps of the scientific method in the solution of problems in biology*. (MNE, 1998, p.139-140)

The previous curriculum saw following the steps of scientific method as necessary in order to produce and guarantee objective knowledge. Another requirement in obtaining objective knowledge in science, according to the previous curriculum, was the characteristics that scientists should have.

(Students should)

- *Explain the characteristics that a scientist should have.* (MNE, 1998, p.139)

Further, the previous curriculum suggested teachers to ask questions such as “List the characteristics of a scientist” in the assessment of learning. Although the curriculum did not provide a list of these characteristics, the textbooks that used the previous curriculum as the framework did. The research study by Irez (2009) revealed that the secondary biology textbooks reflecting the previous curriculum’s approach provided list of characteristics that a scientist should have. These included characteristics such as being objective, honest, hard-working, determined, logical, and sceptical amongst many others.

On the other hand, science is described from a constructivist perspective in the new biology curriculum. For example, the new curriculum introduces science as a dynamic process of generating "testable and falsifiable" explanations about natural phenomena.

(students should)

- *Develop an understanding that science* [scientific knowledge] *has testable, experimental and falsifiable nature.*
- *Realize that scientific knowledge is tested, corrected or renewed in the light of new evidence.* (MNE, 2007, p.17)

This statement also implies the tentative nature of scientific knowledge. Indeed, in various places, the new curriculum emphasize that all scientific knowledge is subject to change. It views the tentativeness of scientific knowledge from a Kuhnian perspective in that change in science is explained as a paradigmatic shift.

(Students should)

- *Explain the role of evidence, theories and/or paradigms in change of scientific knowledge.*
- *Realize that change in science is continuous and sometimes in the form of paradigmatic shift.* (MNE, 2007, p.17)

In contrast to the previous curriculum, the new curriculum does not present science as an objective enterprise. Instead, it suggests that science and society influence each other and perceives science as a product of society and human-culture.

(Students should)

- *Understand that socio-economic and cultural contexts influence the development of biology.*
- *Understand and gives examples about the contributions of societies that have different historical and cultural pasts to the development of biology.* (MNE, 2007, p.17)

Further, the new curriculum does not claim that scientists should have certain characteristics to ensure objectivity in science; instead, it discusses that subjectivity is natural and expected in science.

(Students should)

- *Realize and discuss the effects of different attitudes and values in science.* (MNE, 2007, p.17)

In sum, the analysis conducted with regard to approaches of the previous and new biology curriculum pointed out a significant difference between their depictions of science and scientific enterprise.

THEORIES OF LEARNING

One of the main themes utilized in the comparison of the previous and the new curriculum was their approaches to learning. Results pointed out that, again, there was a significant difference in the approaches of the two curricula.

Although there was not a separate section in the previous curriculum explaining its orientation to learning, close inspection of the unit plans and the sections where suggestions for teaching were presented gave clues about its approach. “Writing and recalling” of the given information was the constant emphasis in the student attainment targets presented throughout the curriculum.

(Students should)

- *Write and/or recall the important discoveries of the scientists who contributed to biology.* (MNE, 1998, p.139)
- *Write and/or recall the living and non-living factors affecting environment.* (MNE, 1998, p.158)

Such statements, according to Tsai (2002), are typical indicators of traditional learning approach. Further, the statements in *Learning-Teaching* and *Suggestions for Teaching* sections were also parallel and supported to such learning approach.

Students should be provided with examples regarding how they can utilize the scientific method in their daily life. (MNE, 1998, p.140)

Important functions (contributions) of biology should be explained. (MNE, 1998, p.140)

As seen, the structure of these statements itself indicates that teaching was perceived as the transfer of knowledge in which the student is the passive receiver without any cognitive involvement in the learning process.

The new curriculum, in contrast, explicitly states that the knowledge can not be constructed without active cognitive involvement of the learner; that comprehension occurs as a result of adaptation in the conceptual change process; that learning of a new concept depends on previous experiences and knowledge; that learning is socially constructed and; that language and social context play an important role in the construction of knowledge (MNE, 2007). In short learning is explained as a conceptual change process. The student's realization of what s/he knows is an important aspect of the process. Therefore, special attention is paid to and explanations are given about alternative conceptions that students may possess in each topic.

This orientation to learning is apparent and verbalized in all attainment targets throughout the curriculum.

(Students should)

- *Realize the limits of the technological development process, its resources and the possible effects of technological applications.*
- *Develop an understanding about the relationship between Science-Society-Environment.* (MNE, 2007, p.17)

The structure of these statements clearly shows the difference in the approaches of the previous and new biology curricula regarding learning. While learning was depicted as a passive process in the previous curriculum, it is perceived as an active process in which the learner's involvement in the construction of knowledge is required.

MODELS FOR TEACHING

It is natural to think that a curriculum's teaching approach is linked to the way it perceives learning. It is because the learning environment should be designed in accordance with how and what students should learn. The analysis of the two curriculum documents revealed that, as expected, they presented teaching approaches that are compatible with their learning orientations.

The role of the teacher in the previous biology curriculum was described as providing knowledge for students in line with its objectives which were presented earlier. Following is an example that gives clues about the previous curriculum's teaching approach.

The non-living factors effecting living things are explained as light, temperature, climate, minerals, water, and pH. (MNE, 1998,Unit 'The Environment and Living Things', p. 159)

As it is exemplified in this statement, what was expected from the teacher was to present (or transfer) certain, absolute and true knowledge to students. According to Tsai (2002) presenting the nature of scientific knowledge in such an absolutist manner is an important indication of traditional teaching orientation. Such statements were abundant in the previous curriculum, as the following is one another example.

The discovery of the cell is taught by narration and experiments. (MNE, 1998, Unit 'The Cell', p. 151)

Parallel to its learning orientation, the new curriculum differs from the previous one in terms of its approach to teaching biology. To this end, the required teacher competencies to meet the objectives of learning are described as follows in the new curriculum:

... constructivists teachers who realize the importance and emphasize the role of student-centred activities, realize individual differences but not disregard social skills, possess an

assessment approach that focuses on the assessment of learning process as well as products... (MNE, 2007, p.17)

Throughout the document, the new curriculum explicitly and implicitly stresses that, in learning process, students should be active and involved in the construction of knowledge. The overall role of the teacher is to guide learning.

ASSESSMENT OF LEARNING

The last theme in the comparison of the two curricula was about their approach in the assessment of learning. The analysis revealed that there were remarkable differences between the approaches.

In line with its approach to learning and teaching, the previous biology curriculum suggested a teacher-centred, summative assessment approach which gives priority to the assessment of learning at the knowledge and/or comprehension levels in Bloom's (1956) taxonomy. The curriculum's approach to the assessment of learning and its suggestions about the ways of assessment were detailed in separate sections at the end of each unit. For instance, about the assessment approach regarding the learning outcomes of the first unit, the curriculum stated;

Exams can be utilized in the assessment of learning outcomes at the end of this unit. (MNE, 1998, Unit 'Biology as a Scientific Discipline', p. 143)

As this statement implies, the aim of assessment was checking whether the learning targets have been met in a traditional way. Analysis of the example questions provided further supported this finding.

How many different types of muscle tissues exist in the body? Write the differences. (MNE, 1998,Unit 'Tissues', p. 169)

The assessment tools suggested in the previous curriculum included classical written exams, multiple choice tests, fill-in-the-blank and true or false questions. This approach and tools for assessment is criticized in the new curriculum.

The new biology curriculum stresses that the assessment of learning process and the skills and attitudes developed in the process is as important as the products (MNE, 2007). It emphasizes that;

Today, along with fundamental knowledge, skills and attitudes, students also need to develop knowledge, skills and attitudes such as critical thinking, creative thinking, problem solving, inquiry, collaboration, scientific reasoning and interpretation, effective communication etc. (MNE, 2007, p. 7)

The new curriculum puts forward that performance (alternative) assessment approaches and tools are needed in order to assess students' performance and progress in these domains. The new curriculum asserts that the impact of this assessment approach can be further strengthened if it is constructed in a way that engages students with meta-cognitive activities and related to real life (MNE, 2007). The assessment tools that new curriculum suggests to the teachers include anecdotal classroom records giving information about the student's performance during classes and rubrics that help the teacher to observe and assess if the student has achieve the expected outcomes. Similar to the previous curriculum, the new curriculum also suggests using traditional assessment tools such as multiple choice tests and fill-in-the-blank type questions. However, it is noted that *'these are not the only ways of assessment'* and encourages the teacher to *'observe and assess students' performances during lab work, group works and other classroom activities.*

CONCLUSION AND DISCUSSION

The analysis conducted in the light of predetermined and emerging themes indicated that there is a remarkable difference, which could be seen as a paradigmatic shift, between the approaches and philosophical standpoint of previous and new biology curricula regarding their curriculum emphasis, approach to the nature of scientific knowledge, theories of learning, the models of teaching and the approach to the assessment of learning. The summary of the main findings are presented in Table 1.

The themes that were utilized in comparing the two curricula are placed on the left hand-side column in the table. The approach of the previous biology curriculum regarding these themes is presented on the middle column whereas the approach of the new curriculum is presented on the right hand-side column.

What this summary and detailed analysis presented earlier illustrated is that a dramatic paradigm shift has taken place at secondary level science education in Turkey. The curriculum reform experienced in Turkey has introduced a new world for teachers, which is fundamentally different from the previous one. In this new educational world, teachers face with new educational aims and objectives, new understanding of the nature of scientific knowledge, a different theory on how people learn and related teaching and assessment approaches. Similar large scale reform movements in education take place almost everywhere in the world (Avenstrup, 2007; Kennedy, 1996). Often, such movements fail to meet with their aims due to strong resistance from the practitioners in the field. Majority of the studies investigating this failure and resistance on the teachers' side attributes to factors such as the top-down nature of the reforms, lack of training, leadership, communication, etc. as the reasons.

The results of this study can be interpreted that the overall reason for resistance to change on teachers' side may be the difficulty (if it is not impossibility) for teachers to comprehend the conceptual framework of the reform (or the new paradigm) as this requires denying the previous educational context in which they established themselves in. Considering the fact that the majority of the current biology teachers in Turkey completed their pre-service education in the framework of the previous curriculum and established themselves and their practices using the theories and approaches embedded in it, they, more than probably, will choose to refuse implementing the new education program with its new approaches. Utilizing Kuhn's (1970) perspective, it can be argued that the greatest resistance would come from the more experienced whereas the new teachers may be more open-minded.

What the results and discussion in this study also implies that these reasons put forward by teachers to explain the reasons for their resistance, such as lack of leadership and the top-down nature of the reforms, in majority of the studies in the field may not be the reasons but their "justifications" for resistance. The aim of this discussion and tentative conclusions produced is neither to treat teachers' accounts as delusions nor to underestimate the findings of the established literature in the field. Also, we are aware that such a discussion requires evidence. This study is a part of a research project that aims to assess educational reforms and teacher resistance using the discussed framework. We believe that viewing change as paradigm shift can be a pivotal conceptual and methodological approach for better understanding the implementation process of and teacher resistance to large-scale educational reform (Schmidt & White, 2004).

Table 1.Summary of the comparison of the two curricula

Themes	***Previous Biology Curriculum***	***New Biology curriculum***
Curriculum Emphasis	Correct Explanations Everyday Coping	Structure of Science Science Technology & Decisions Scientific Skills Development
Nature of Scientific Knowledge	Existing truth or reality Science as body of knowledge Science as collection of facts Verification Objective Scientific knowledge as factual and absolute Cumulative progress in science	Explanations about natural phenomena Testable and falsifiable Contextual Subjective All scientific knowledge is tentative Cumulative and Paradigm Shift
Theories of Learning	Behaviourism Memorizing scientific truths Experiments as a process of verification Transfer of Knowledge Teacher-centred	Constructivism Conceptual change Concept maps Construction of knowledge Student-centred
Models for Teaching	Teacher as a expert Provide clear definition Give accurate explanations Present scientific truths	Teacher as a guide Pay attentions students' misconceptions Interacting with students
Assessment	Summative Assessment of products Traditional assessment tools End of unit assessment	Formative Assessing processes and products Alternative assessment tools In process assessment

ABSTRACT

Few studies have been done in Norway to evaluate our own education of science teacher students, despite that this could give invaluable information to improve the courses to be more useful for coming science teachers in real teaching situations. To evaluate our science courses, we sent out a questionnaire to former science students. In addition to questions about the relevance of the science education they were given at Nesna University College, we also asked questions about related topics like teachers attitudes to science and experiences in science teaching, what happens in the classroom, equipment and teaching conditions at the schools, text books and the need for professional updating. Major findings were that the students were mostly satisfied with the foundation they had gotten in our science courses and although the chemistry part had the lowest score it was still quite positive. The science teachers revealed a need for continuing education in subjects like chemistry and physics, as well as in Science and Technology, and they also wanted to learn more about equipment and instruments.

Keywords: *teacher students, science, evaluation of science courses, pupil-activity, questionnaire, continuing education*

INTRODUCTION

Nesna University College has from 1978 given becoming teachers (in this paper called students) an opportunity to specialize in how to teach science subjects (physics, chemistry, biology, geology and science didactics) in school, especially for primary school and secondary school. We have no special prerequisites for course entry, and it is the same course for both primary- and secondary school teachers. A main goal with our teaching has been to let students work with active learning methods like hands-on experiences, outdoor education, group work and discussions, all based on the constructivistic view of learning. By focusing on activities, there has been less time for the theoretical aspects of the science in the education. We have focused on teaching students to use concepts and explaining models which can be used in primary and secondary school (Olsen et al., 2008).
We will compare some of the findings from this investigation with results from Norway from TIMMS (Martin et al., 2007) and SISS (Sjøberg, 1986). The relation between the science teacher education and the in-service teaching practice has previously been studied by Andresen and Tveita (1993). The present study is a follow up study to find out more about

how the teachers who have specialized in science at Nesna University College have experienced life as science teachers. We will in this paper give an overview of the main results from the project and with the main focus on the following questions:

How did our former students consider the content and relevance of the science courses that were given at Nesna University College to meet their needs in teaching pupils? What was satisfactory and what should be improved?

METHODS

A questionnaire was worked out and tested on 5 former students that then were interviewed about it to get feedback. After revision, it was sent out to all 224 former students (99 males and 125 females) who had specialized in science in Nesna in the period from 1990 to 2007. Of these, we have received answers from 116 (50 male, 64 female, 2 did not answer about gender; 46 only primary school- and 26 only secondary school teachers), a response rate of 52 percent. We have an ongoing follow up study to find out why 48 % did not answer. The questionnaire was divided into sections with questions about the following parts:

A: Background information
B: Teaching experience
C: Teaching practice and what happens in the classroom and to what extent the teachers wanted changes in their teaching
D: Equipment available for science teaching
E: Attitude and experience with science
F: Need for follow up education
G: Relevance of the science courses at Nesna University College
H: Attitudes to science

Data on Likert scales (mostly from 1 to 5 with a neutral value of 3.0) were transformed to a decimal number (0.00-1.00). SPSS (Version 17.0) has been used to calculate means, and implement t-tests as is commonly done for this kind of data, although data on this form is non-normal distributed. Level of significance is given when appropriate. Means are given with standard deviation.

Factor analysis was used to see if we could identify different types of teachers based on what they reported to happen in their science classroom. We made a rotated component matrix in SPSS (Rotation method: varimax with Kaiser Normalization, excluding cases pair wise). Factor analysis is a technique that analyzes the structure of correlations in data sets consisting of many items to determine whether there are common underlying dimensions/factors (Sannes, 2005).

RESULTS AND DISCUSSION

General feedback on our science courses and teachers need for follow up studies

This paper deals with the answers from most parts of the investigation. More results from part C are presented by Sørmo et al. (2010). Overall, the students seemed to be satisfied with the basis they had after taking our science courses as they gave a score of 0.76 ± 0.18 on a general question about the relevance of what they had learnt. For the biology and physics parts they were also very satisfied (Scores of 0.70 ± 0.20 and 0.68 ± 0.19) whereas for chemistry the score was somewhat lower (0.58 ± 0.20), although still above the neutral value. High scores were also obtained for the methodical and didactic parts of the science courses (0.68 ± 0.21), field work (0.75 ± 0.19) and for experiments (0.76 ± 0.22).

There is of course a connection between what they need follow up studies in and what they were least satisfied with in the science classes, as is easy too see for chemistry (0.64, Table 1). The need for continuing education among our teachers varies between 0.37 and 0.72 (Table 1). The highest scoring topic is “becoming more familiar with apparatus and equipment”. Second and third is “technology and design” (0.67) and “budding researcher (young researcher)” (0.65). This makes it clear that the teachers feel they need more education in many of the new elements in the new curriculum (LK-06), such as “Budding researcher” and technology and design.

Table 1. Teachers need for continuing education. The scale runs from 0 (no need) to 1 (highest need), and there is no neutral for this scale. N = 90.

The need for continuing education	All	Primary	Secondary
Become more familiar with apparatus and equipment	0.72	0.70	0.73
Technology and design	0.67	0.65	0.74
Methodology in relation to the implementation of the “Budding researcher” and the new curriculum (LK-06)	0.65	0.64	0.71
(academic) Update in chemistry	0.64	0.59	0.68
(academic) Update in physics	0.63	0.56	0.71
Presentation and testing of ready-made teaching plans and science experiments	0.63	0.62	0.66
Excursion methods and ideas	0.62	0.59	0.66
Project methodology and ideas	0.61	0.64	0.56
Use of models in science teaching	0.60	0.60	0.58
How to evaluate in school science	0.58	0.56	0.58
Learn about pupils' alternative conceptions and how to identify them	0.56	0.58	0.51
Science teaching and pupils' daily live	0.52	0.51	0.53
How to find pupils' prior knowledge	0.51	0.54	0.45
Science education and social issues	0.51	0.49	0.52
Coordination of the natural sciences with other subjects	0.49	0.53	0.44
Computer as an aid in science teaching	0.49	0.53	0.44
Cooperation of science subjects	0.48	0.52	0.41
(academic) Update i biology	0.41	0.41	0.39
Review and critique of curricula and learning material	0.39	0.40	0.39
Topics from the history and philosophy of science	0.35	0.37	0.29
Average	**0.55**	**0.55**	**0.55**

It seems that the teachers are in need of academic update in both chemistry and physics, but less so in biology. This harmonises with findings in TIMMS (Martin et al., 2007) that indicate that Norwegian teachers feel more insecure in chemistry and physics topics compared to biology.

The average score for primary- and secondary school teachers for need for all kind of continuing education is the same (0.55). However, primary school teachers do not emphasize academic update as much as teachers in secondary school, but emphasize either projects, collaboration with other disciplines, presentation and testing of ready-made arrangements. Secondary school teachers, on the other side, have more need for continuing education in chemistry and physics.

When it comes to gender differences, females report a slightly higher need for continuing education than males (Table 2). When all differences less than 0.05 are omitted, all gender differences are in favour of the females (Table 2). This is in contrast to what extend they actually are participating in this kind of education, where the females score is 0.64 while the males score is 0.72 (these figures are not reported in the tables). This is a striking contrast, because the females say they are in need of more continuing education compared with the males, but they participate less in this kind of education than the males. Possible explanations could be that the males feel more secure because of their participation in continuing education. It might also be explained by gender roles, as maybe women do not want to travel away from the family to get continuing education in the same extent as men? However, follow up studies are necessary to find explanations for this.

The greatest gender difference was the need to become more familiar with apparatus and equipment, where the difference is 0.19 (statistically significant, $p < 0.01$). This is, however, not surprising because we often observe that the males dominate in the classroom during experiments and thus become more accustomed in using equipment.

Table 2. Gender differences in need of continuing education. Only differences more than 0.05 are shown.

The need for continuing education	**Female N = 52**	**Male N = 38**	**Female-Male**
Become more familiar with apparatus and equipment	0.80	0.61	0.19
Science Teaching and pupils' daily life	0.56	0.45	0.11
(academic) Update in physics	0.68	0.58	0.10
Cooperation of science subjects	0.57	0.47	0.10
How to find pupils' prior knowledge	0.56	0.47	0.09
Presentation and testing of ready-made teaching plans and science experiments	0.64	0.56	0.08
Project methodology and ideas	0.64	0.56	0.08
How to evaluate in school science	0.61	0.54	0.07
Learn about pupils' alternative conceptions and how to identify them	0.60	0.53	0.07
Technology and design	0.69	0.63	0.06
Average of all statements	**0.58**	**0.53**	**0.05**

Table 3 shows that the teachers report the most common aids in science classes to be projector, computers and internet. It seems clear that the infrastructure in the classroom is good, but the equipment for science activities is more lacking. It is also clear that equipment for teaching astronomy and geosciences are in short demand. Many of the teachers report that they do not have a classroom especially equipped for science teaching as 41 % are lacking science classroom all together.

Table 3: Aids in science teaching. The scale runs from 0 (no equipment) until 1 (perfectly equipped). The last column is the sum of the two first columns. N = 90.

Aids in science teaching	**Lacking equipment**	**Poorly equipped**	**Intermediate equipped**	**Well equipped**	**Poorly or less**
Astronomy	0.23	0.60	0.14	0.03	**0.83**
Geosciences	0.16	0.54	0.24	0.06	**0.70**
“Smartboard”	0.56	0.10	0.13	0.21	**0.66**
Activities in physics	0.06	0.53	0.29	0.12	**0.59**
Science classroom	0.41	0.16	0.27	0.16	**0.57**
Video, film and pictures	0.09	0.47	0.32	0.12	**0.56**
Activities in chemistry	0.07	0.47	0.32	0.14	**0.54**

Animals and plants	0.03	0.42	0.42	0.13	**0.45**
Body and health	0.03	0.33	0.52	0.12	**0.36**
Manuals and encyclopaedias	0.01	0.29	0.54	0.16	**0.30**
Computers/internet	0.03	0.16	0.35	0.46	**0.19**
(Video-) Projector	0.07	0.08	0.29	0.56	**0.15**
Average	**0.14**	**0.35**	**0.32**	**0.18**	**0.49**

When asked if access to a science classroom limits the possibilities for good science teaching, the teachers in primary school agree more to this statement (score 0.61) than the teachers in secondary school (score 0.41). Norwegian primary schools are mostly lacking science classrooms, but the results clearly show that this affects the science classes. Also, we find a gender difference for this statement (female 0.61 vs. males 0.48), but this is probably mainly because there are most females working as teachers in primary schools.

Teachers' goal for science classes

We have asked the science teachers about which goals they consider most important for their classes. Most of the goals are the same as in Andresen and Tveita (1993) and Sjøberg (1986) so that we can compare and see if there have been any changes over about 20 years. Table 4 shows the figures from these studies arranged in sequence of what the teachers in our study consider the most important goals for their science classes.

Table 4. Ideally most important goals for science teachers for classes in science. Scale from 0.00 to 1.00 where 0.50 is a neutral value. Also given are data from Andresen and Tveita (1993) and SISS (Sjøberg, 1986). Last column is the difference between the scores in the present study and Andresen and Tveita (A & T) (1993). N = 102.

	Goal	Present study	A. & T.	SISS	Diff. to A. & T.
1	To stimulate interest and curiosity	0.95	0.94	-	0.01
2	To develop respect for and solidarity with nature	0.92	0.96	0.87	-0.04
3	To develop attitudes for a sound use of natural resources	0.91	0.97	0.87	-0.06
4	To develop a questioning attitude	0.91	0.88	-	0.02
5	To take care of own and others health	0.89	0.91	0.78	-0.02
6	To develop independence and respect	0.87	0.80	0.73	0.06
7	To develop a critical sense for the possibilities and limitations of science	0.86	0.68	0.74	0.18
8	To impart science as intellectually exciting and stimulating	0.83	0.67	0.64	0.16
9	To develop an understanding for the importance of science	0.83	-	-	-
10	To maintain and develop girls interest for science	0.81	0.73	0.70	0.08
11	To impart science as part of our culture	0.80	0.56	0.63	0.24
12	To prepare for daily life	0.79	0.84	0.77	-0.05
13	To understand important concepts, laws and theories	0.78	0.63	0.73	0.15
14	To develop systematic problem-solving techniques	0.78	-		-
15	To prepare for decisions in society	0.77	0.76	0.68	0.02
16	To develop scientific method of work	0.76	0.68	0.64	0.08
17	To prepare for education and work	0.76	0.61	0.73	0.15
18	To supply society with technologically highly skilled workers	0.73	0.53	0.54	0.20
19	To develop skills and techniques in use of instruments and equipment.	0.63	0.51	0.59	0.11
20	To prepare for tests and exams	0.55	0.25	0.45	0.30
	Average	0.81	0.72	0.69	0.09

The scores from the present study is on average 0.09 higher than what Andresen and Tveita (1993) obtained, and this may show that the science teachers consider many goals as more important for science in school today. The largest change between the two studies (differences in scores) is for the goal "To prepare for tests and exams", with more than a double value in this study, even though this still is ranked as the least important one (as also in SISS (Sjøberg, 1986)). We believe that this is a reflexion of the debate in Norway about national tests of pupils the last years. Also, the results and debates after the latest TIMMS and PISA investigations have led to more focus on the importance of testing and results from test of pupils in science.

Also scoring much higher in the present study are the goals "To impart science as part of our culture" and "To supply society with technologically highly skilled workers". This may also be a result of today's political discussions in Norway, and the importance of technology is especially stressed in the new Norwegian curriculum (LK-06).

Whereas the scores are higher in the present study, a few goals have lower scores, compared to the 1993 study (Andresen and Tveita). The goal "To prepare for daily life" scores 0.79 in the present study, opposed to 0.84 in Andresen and Tveita (1993), and is now closer to the value of 0.77 from SISS (Sjøberg, 1986). Also, the scores for "To develop respect for and solidarity with nature" and "To develop attitudes for a sound use of natural resources" are lower in the present study. However, the scores are still among the highest, and the reduction is most likely because these already had very high values in Andresen and Tveita (1993) (Table 4). This is also reflected if we rank the goals, in that these two goals are ranked among top 3 in both investigations. Other differences in ranking are that "To impart science as part of our culture" is ranked much higher now (11 vs. 15) and that "To prepare for daily life" and "To prepare for decisions in society" have dropped down on the list (from place 6 to 11 and from place 8 to 13, respectively, excluding questions from the present study which were not included in the two previous studies).

The scores from SISS (Sjøberg, 1986) are on average 0.12 lower than in the present study and comparable to Andresen and Tveita (1993), although SISS included all teachers in primary school and science teacher in secondary school (average of both is used here). The ranking of the goals is quite similar, maybe except that "To impart science as part of our culture" also scores low in SISS compared to the present study (ranked as number 13 vs. 8, out of the 16 goals).

We found only small differences between primary- and secondary school teachers about what goals they consider most important for their classes (data not shown as they are very similar to data given in Table 4). This may to some extent be because they all have a similar education in science from Nesna without any specializing for either primary- or secondary school.

Gender differences in goals

It was striking to find that there were very slight differences between the sexes about what were the most important goals for their science classes. Out of the 20 goals, 14 had less than 0.05 in difference and for the remaining, 5 had exactly 0.05 in difference (Table 5). Goals with some differences are shown in Table 5 (the rest of the values with gender differences less than 0.05 can be found in Table 4).

Table 5. Gender differences between the most important goals for science classes. Only goals where difference between sexes was 0.05 or more is shown.

Goals	Both	Male N= 43	Female N = 57	M – F
To develop independence and respect	0.87	0.84	0.89	-0.05
To impart science as part of our culture	0.79	0.76	0.82	-0.05
To prepare for decisions in society	0.78	0.75	0.80	-0.05
To develop systematic problem-solving techniques	0.78	0.81	0.76	0.05
To prepare for education and work	0.75	0.78	0.73	0.05
To supply society with technologically highly skilled workers	0.73	0.79	0.69	0.10
Average of all 20 goals	0.80	0.81	0.80	

It is remarkable that the average score was almost identical and that we found some gender difference for only one of the 20 goals, for the goal "To supply society with technologically highly skilled workers" where the score for boys was higher (P = 0.047, *t*-test). Science and technology (STS) is more stressed in the new Norwegian curriculum (LK-06) than it has been before, and it is possible that girls feel more uncertain in especially technology.

Identity as science teachers

We have in an earlier publication from this project shown that teachers from Nesna like to teach science and have an identity as science teachers (Olsen et al., 2008).

Table 6. Factor analyses: Rotated Component Matrix. Rotation Method: Varimax with Kaiser Normalization. Extraction: Numbers of factors: (5). Options: exclude cases pair wise, suppress absolute values less than (0.3), sorted by size. N = 90

Rotated Component Matrix	1	2	3	4	5
Performs experiments or investigations	0.797				
pupils do experiments	0.783				
Let the pupils conduct experiments or investigations	0.783				
Designing or planning experiment of investigations	0.754				
Work in group with experiments or investigations	0.683

In Norwegian schools, many teachers who teach science are not specialized in science and have to teach other subjects as well, even subjects they have not had any deepening in their education. As a result, there will be differences in the way they identify themselves as science teachers. We have analyzed (factor analysis) the data to see if we can identify different types of teachers, and the analysis showed that the science teachers could be grouped into 5 different types of teachers, see Table 6. The 5 different types (one in each column, Table 6) of teachers we have identified can be described as follow:

The first type of teacher (Column 1, Table 6) seems to be a teacher using scientific methods of work, and therefore use these methods as the most important part of her/his classes. The pupils do many experiments and investigations, and they want the pupils to learn how to formulate and test hypothesis, and to observe and write report from the experiment.

The second type of teacher (Column 2, Table 6) seems to be a teacher that is concerned about if the pupils understand the science that has been taught. The teacher goes through new material, teaches about the nature of science and scientific methods of work, and allows the pupils to explain and write down the explanation, and why it happened. They are discussing science that has been in media, and give the pupils homework and hear them in homework as well.

The third type of teacher (Column 3, Table 6) seems to be a teacher that prefers to use projects in their classes. He/she wants the pupils to find information themselves rather than listen to the teacher most of the time. The pupils use other sources than the textbook to find information, such as PCs, the internet and media (newspapers and TV). The teacher also allows the pupils to take part of the planning of the lessons.

The fourth type of teacher (Column 4, Table 6) seems to be a teacher that is more pupil-focused. The base for teaching is the pupils' prior knowledge and everyday notions. This teacher tries to link what they learn in science to everyday life, and use activity based learning such as discussions, role play, drama and field work and excursions.

The fifth type of teacher (Column 5, Table 6) seems to be the traditional teacher that writes on the chalkboard, and let the pupils read the textbook before they do written exercises. To check that the pupils have gotten an understanding, they test them orally.

It was interesting to see that 5 recognizable types of teachers could be identified, even if it is not correct to assume that all science teachers can be placed into (only) one of the types. But the fact that the type 5, the more traditional teacher, can be identified among the teachers shows that we still have room for improvement as we want the science teachers educated at Nesna University College to be pupil oriented and use varied teaching-methods like many hands-on activities etc. However, many other factors will of course influence the teachers as they are a very inhomogeneous group with different attitudes and previous experiences.

These results will be used to make constructs for further analysis to find about more about the different types of teachers that we have identified, but the results are interesting and will also be use directly in our science education courses.

CONCLUSION

This survey has given us valuable input about parts of our science courses that need improvements and refinements, and it is also clear that we will have to put even more emphasis on the physics and chemistry part in our science courses. We do have student evaluations in every class, but it is just as important to get feedback from the teachers (former science students) after they have been teaching science in school and then have more experience and a better understanding of the needs they have in real teaching situations. However, we have also received feedback on what parts of our science courses that students are satisfied with and that we should not change. We have also many interesting results that we will use directly in our science education courses (E. g. about teachers types). Another benefit from the project is that it has initiated several follow up studies, see Ellingsen et al. (2010) and Tveita and Henanger (2010), and we have identified more subjects that we would like to follow up in separate studies.

THE ROLE OF NCCP TIME FOR ENHANCING CHILDREN'S CREATIVITY IN TECHNOLOGY

ABSTRACT

The focus of our research project was the question Can children's creativity be enhanced by including a period of non-conscious cognitive process (NCCP) time? During this non-thinking time the brain makes connections between independent ideas, forgets inappropriate responses, and makes available more relevant responses for problem solving. The research generated cases of several primary school classrooms as the teachers incorporated NCCP time in their design technology sessions. Children were observed and teachers interviewed about their perceptions of children's creativity as the children designed and produced recycling devices. The cases revealed an optimum time frame of several days for non-conscious cognitive processing. These findings have implications for teachers of technology who assign the same day and time each week for technology learning. During the non-task time, which included the NCCP time, children were able to discuss their ideas with family members. As children learn in socio-cultural contexts, these discussions can be fruitful. The teachers indicated that peer discussions also played an important role after the generation of designs.

Keywords: *Children's creativity, design technology, non-conscious cognitive processing (NCCP) time.*

INTRODUCTION: CREATIVITY IN TECHNOLOGY EDUCATION

Creative problem-solving is an integral component of technology education in schools (Barak & Goffer, 2002). Peterson (2001) contends that "Creativity is closely associated with advances in technology, and it is logical that an important aspect of technology education is the development of creative abilities". He recognizes that creativity in technology education relates to students being actively engaged in generating novel products as solutions to technological problems. The broad range of topics and the versatility of approaches that can be included within the technology classroom provide a range of opportunities for the technology teacher to implement programs aimed to foster higher order thinking skills – in particular both analytical and creative thinking. A structure that employs a careful balance between content knowledge and process (Jones, 1997) but also successfully incorporates higher order thinking should be implemented within the technology classroom (Middleton, 2005).

In the technology process, it is through the imposition of the unsolved problem that stimulates the thinking student to discover a viable solution to satisfy a human and/or environmental need. This aspect of the technology process suggests that the learner seeks innovation in a practical context. Creative and analytical thinking support cognitive processing in the context of student problem-solving and therefore are compliant in sustaining the development of the technological knowledge, skills and values, according to Howard-Jones (2002) who proposed a model of creative cognition for supporting strategies that foster creativity in the classroom. Howard-Jones also suggested that when thinking creatively, children generate new ideas through remote associations and brainstorming and this type of thinking is enhanced when attention is allowed to wander in a relaxed and uncompetitive environment. Other researchers (such as Forgays & Forgays, 1992) have also indicated that being involved in unrelated activities have promoted solutions to problems and increased children's creativity. Larger numbers of initial ideas also increased the likelihood of children developing a more original final solution (such as using brainstorming sessions). To allow the generative state to occur, Howard-Jones (2002) suggested the use of a period of time in which student attention is not focused on the technology task. This time allows the individual to be able to sub-consciously combine concepts and produce novel combinations of remotely-associated ideas. It was this idea of a non-conscious cognitive process (NCCP) time that was tested in a study by Webster, Campbell and Jane (2005) in an intervention program undertaken in primary technology classes. Reflection on that research has enabled us to theorize how design technology education with a built in NCCP time can contribute to children's creative thinking.

AIMS OF THE RESEARCH

The overall purpose of the research was to investigate the notion that children's creativity can be enhanced through the inclusion of a non-conscious cognitive processing (NCCP) time in the technology process. The purpose of the research was two-fold. Firstly, we aimed to explore the structures, relationships and content of the technological experiences at several school settings. This exploration entailed engagement of the interpretive categories of the social, educational and professional values, beliefs and attitudes of the main participants. Secondly, we aimed to study how the children's creativity was enhanced through the introduction of an intervention strategy – that of NCCP time.

RESEARCH DESIGN

In our preliminary discussions we decided that a case study approach would be most appropriate as our basic intention was to seek to describe and develop an understanding of the setting and the children's creativity, rather than for the research to be an active agent in evaluating outcomes or instigating change. However, an intervention process was also required, as in discussion with our teacher participants, we realised that what we were suggesting, was something new and different to their normal classroom practice.

Accordingly we developed case studies of each of three sites – primary schools in the state of Victoria, Australia, by gathering data to describe the experiences of the children and teachers, and to illuminate the approaches to learning and the developing creativity. Both the perspectives of teachers and children were sought. Since this interpretive study was 'bounded' in both time and space, we identified the case study as the most appropriate research approach due to its capacity to accommodate the complexity of the situation as it actively engages the changing dynamics of the setting and its social aspects (Campbell 2000 p. 80). Additionally we recognized the validity and compatibility in this study of Stake's assertion (Bryman 2001, p. 55) that 'The utility of case research to practitioners and policy makers is in its extension of experience'; and that case studies centre on '…research on a single case with a view to revealing important features about its nature'.

Each setting or site we investigated was a 'bounded system' in several ways. From the physical perspective, the system is located as a dedicated area and described by the specificity of the technology task within the classroom environment. One school was in an urban area, one in a rural area and the third in a regional centre. Each site is also bounded in that we collected information over a specific period - a snatch in time. The research approach needed to be sensitive to the constraints and opportunities that presented within the research study. Reflection on the data enabled us to provide an interpretation of the learning related to enhanced creativity exhibited by the children as evidenced by the technological products they produced within the context of each site.

Participants were primary school children and their teachers, situated in three schools across the state of Victoria, in metropolitan Melbourne, regional Geelong and rural Mornington Peninsula. Two teachers (at year three or four level) from each school agreed to participate in the study and their role was to teach a technology unit across at least four lessons. Surprisingly to us, most of these teachers had no practical experience teaching technology, although they had taught science. Accordingly, professional learning sessions were conducted with the teachers to ensure that they were aware of what classroom technology was in practice. These sessions led to a change in their approach, with most teachers incorporating some form of brainstorming at the start of the process. Another change in practice was allowing the children time during the planning and construction time to 'think through' their ideas and problem-solve with others. Problem-solving thinking is an important aspect that can lead to enhanced creative thinking. The study was conducted in an authentic setting – the normal classroom in which children's learning occurred. The children worked in pairs or small groups to address the following open-ended design brief.

> Design and make a model of a small recycling device for the home or garden. Your product should be made mainly from recycled materials.

The teachers were requested to incorporate NCCP time between session one - when the design brief was introduced and the brainstorming (or familiarisation process) was undertaken - and session two. In practice the NCCP time varied from school to school, depending on the classroom timetable and time constraints. The length of NCCP time was: School A~ 5 days, School B ~3 days, and School C~ 7 days for one class, 14 days for another class. In this way the teachers gave children thinking time or extended periods where discussions between them were encouraged. Teachers also allowed modifications after the evaluation time. Children were encouraged to document their ideas in a journal - *My Thinking and Ideas Book,* as a means of recording previous ideas and being able to return to them should they wish. The journal belonged to the child and was not assessed by the teacher as part of the process. This approach gave the journal some legitimacy in the children's minds as a personal tool rather than a teacher requirement.

As it was not our intention as researchers to take an artefact focus, we studied the generation of new or different solutions as a function of creative thinking, by taking account of the children's initial suggestions for their recycling devices, both written and drawn. Evidence of the children's involvement in the technological process was obtained through their documentation of their drawings, ideas, sources of ideas and reflections in their journal - *My Thinking and Ideas Book.* We spent time in the classrooms observing the children as they engaged in the technological process, and listened as the children shared their technological knowledge during presentations to their peers. Informal conversations occurred naturally with the children as they eagerly shared with us how they made their recycling devices. Photographs of children's designs were taken, both from the point of view of illustrating any novel or creative idea but also as a validation to the children of the value of the task. Once the technological unit was completed, we carried out informal interviews with the teachers who revealed their perspectives of the influence of NCCP time on children's creativity.

RESEARCH RESULTS

In responding to the Design Brief, most children indicated that they read books and spoke with their parents, teachers and each other, in an attempt to think of something that was new, or at least different, to what was currently available on the commercial market. Many took examples of familiar items and attempted to modify them so that they were more efficient or ‘better’. Some tried to think of an entirely new way of approaching the problem or issue. As part of their routine classroom studies, the children had a strong understanding of the background information about recycling and environmental health. For most of them, the topic was sufficiently familiar that they did not need to have additional information. However, the teachers did spend some time brainstorming both the idea of recycling and discussing aspects of the design task required of the children. The following comments are representative of the teachers interviewed.

- Children were frustrated with that [NCCP time] because they wanted to get started.
- In hindsight, a week for incubation [NCCP time] was too long.
- Once they had set up what they wanted to do…very, very rarely did they change that idea. The kids that changed mostly were the more practical kids.
- Unexpectedly several children who had not been observed showing creativity prior to the task, had generated very unusual designs.
- There were ‘quite a few’ children who needed to change their designs to accommodate functionality.
- Additionally, children had to modify their designs based on limited resources or limited personal manipulative skills. This they found particularly frustrating – having an idea but not being able to produce from it.
- There were not many new concepts that the children could generate, but there was a diversity of ideas within a particular topic.
- The children needed to have an adequate understanding of the topic. Children who possessed a broader knowledge of recycling appeared to produce devices that were different.
- Allowing children to take their ideas home was particularly helpful as this gave them time to discuss ideas with family members.
- Some children showed original, creative thinking, while others ‘shared’ ideas with their peers and then made modifications.

The children’s creativity was demonstrated in various ways. How the children approached developing the design of the product indicated an engagement with the creative ideas. The novelty aspect was evident in some of the children’s designs. One Year four teacher commented; “some children came up with their own, original ideas (e.g. theme park for worms!). Some designs involved a variety of processes (e.g. crushing, rolling etc.) that were creative”. The designer of the worm farm wrote in her journal.

My worm farm recycles food scraps. It has a playground and a sorting belt that sorts out scraps. I was thinking how to construct my model and what to use. The worms break down the vegetables and turn it into compost. My worm farm looks good because it’s different to everyone else’s project. It is different to what I’ve seen because it involves my own ideas. If I had different materials I would make an improved version. I think my project is a great success and I’m proud of myself (Year four girl).

Throughout the construction of their devices, the children were actively involved in a problem-solving process – often having to devise new solutions. Some children created novel ideas, but were hampered by the limitations of resourcing and even expectations of their age group. One child had a very creative idea to clean a cat litter tray using a magnetic force. Unfortunately, practicalities forced her to abandon her original creative idea and to move to something that was ‘do-able’. Another child, at a different site, wrote in his journal that he was so frustrated by not being able to complete his fire-log maker machine as he wasn’t allowed to use electricity and didn’t know how to do that part anyway. In the end, he created a box with specific instruction on the outside, but no content, because he could not include any machinery.

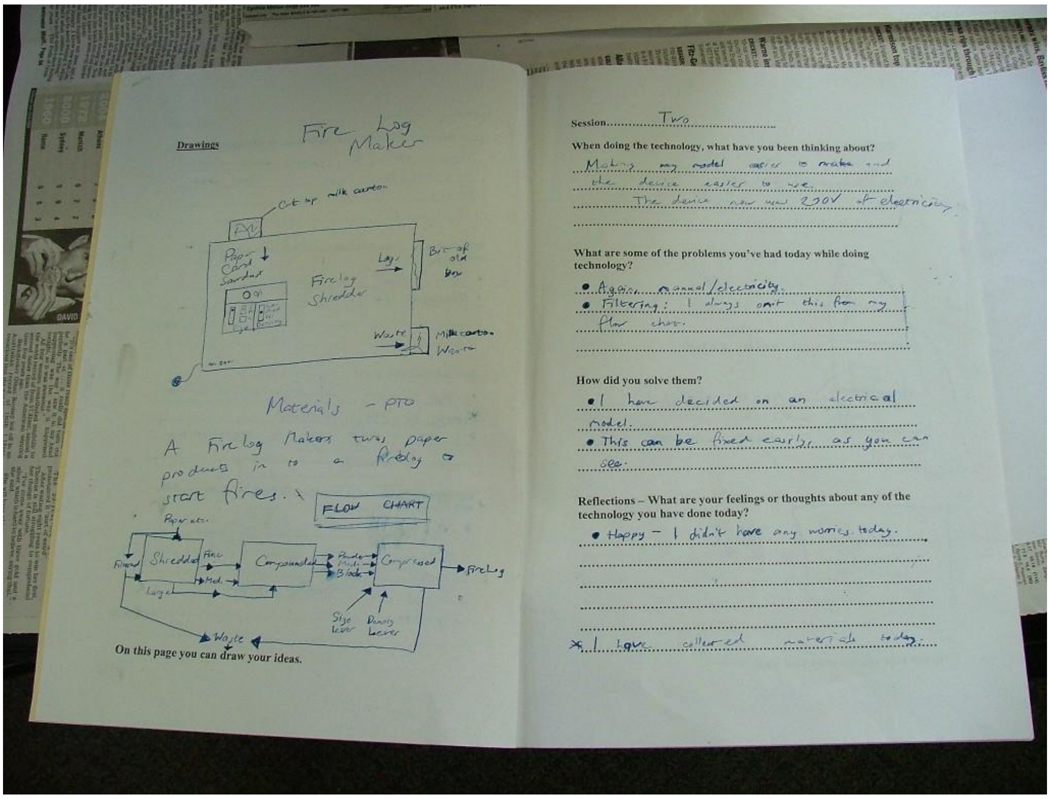

Figure 1 – My Thinking and Ideas Book - entry for the Fire- log maker

DISCUSSION: SOCIAL CREATIVITY AND NCCP TIME

In that intervention program, at all three sites, teachers took time to introduce the task, to brainstorm or to undertake familiarization activities prior to the children commencing the project. Time was spent clarifying with the children what the design brief and the specifications meant. Teachers were aware to leave the task as open-ended as possible so that they would not impose further restrictions or specifications outside the design brief itself. This allowed children to interpret the task in their own mind and by their own set of understandings and experiences. We observed that children already had strong content knowledge of environmental education – refuse, reduce, reuse and recycle was a theme that had already been introduced to the children previously.

During the interviews the teachers commented that allowing the children to discuss their ideas with family members was beneficial. This valuing of community orientation to learning, rather than viewing learning from an individual's perspective, is consistent with Gordon's phenomenological study of eight families involved in *Starwatcher* activities. Gordon (2006, cited in Fleer & March, 2009) found that engagement in learning was enhanced through experiential learning when children and adults participated in hands on activities associated with astronomy. Our study identified that the provision of time between sessions allowed children to discuss their ideas amongst their peers and family members, thus deepening their content knowledge (as a prerequisite for creative thinking) and allowed NCCP time to be activated. In so doing, shared expertise and social creativity came into play. In her study on expertise and creativity, Reilly (2008) expanded the notion of expertise by not restricting it to being situated in an individual. Rather it "can emerge from a system of shared experience" (p. 59). Our study revealed that the path from the initial introduction of the design brief to ideation involved two or more people over an extended period of time. The NCCP time was occurring outside these social interactions, but providing further 'new ideas' to be discussed with others. Thus the shared time can facilitate social or collective creativity. Barrett (1999, cited in Reilly, 2008) points out that “Social creativity has come to mean the functional and dialogic relationships between persons concerning a task embedded in a specific environment, which is nested in a socio-historical frame” (p. 64). In our study, when the children worked together in pairs or small groups on the technological task, language became a tool of creativity. Therefore dialogical interaction in the context of technological activity can foster creativity. Solutions to problems can emerge through conversations between group members. So the ‘copied’ ideas that are then modified can be viewed as part of a social creativity process. Even for those children who tended to work alone and appeared to generate their own novel ideas, the social context would have provided additional stimulus for creativity.

CONCLUSION

In undertaking this research, our initial aim was to ‘enhance children’s creativity through the inclusion of a non-conscious cognitive processing time (NCCP) in the technology process.’ This was a distinct intervention. We acknowledge that other factors such as brainstorming, task criteria, children’s knowledge, learning dispositions and higher order thinking practice all aid a child in the development of their creative thinking. These other factors became apparent at the time of talking with the children and teachers about the entire process. While we can definitively state that the inclusion of NCCP time enhanced creativity, the other factors were present as part of normal classroom practice. This is a very positive outcome of the research – that many of the pre-conditions necessary to enhance creativity are already present in some classrooms.

The use of the non-conscious cognitive processing (NCCP) time cannot be ‘taught’. Rather it is activated at the individual level through free-flow mental states. Remote mental connections can be made non-consciously which produce unusual and original ideas. The implication of our study for teachers is that when NCCP time is allowed for in curriculum planning, and incorporated as part of the technological process, novel ideas and creativity are enhanced. With the provision of NCCP time comes a period of non-task time when children are given opportunities to informally share their fledgling ideas in a social context. Teaching design technology in this way can contribute significantly to enhancing children’s creativity.

ACKNOWLEDGEMENTS
We appreciate the involvement of the teachers and children that participated in this study.

SECONDARY STUDENTS' INTEREST IN SCIENCE AND TECHNOLOGY UNDERSTOOD AS A MEDIA EFFECT

Anders Jidesjö

Linköping University in Sweden

anders.jidesjo@liu.se

ABSTRACT

Young people's interest in science and technology and their attitudes towards those knowledge fields has been an object for research for a long time. Current research points to cultural aspects and informal learning as important to understand these questions. In this study I use content analysis to compare what secondary students want to learn about in science and technology with what international popular science television program broadcast and present important similarities. I discuss the results from media theory as modernity having an effect on young people's experiences and that this can be important in understanding the way they encounter school science.

Keywords: *Students' interest, Science, Media*

INTRODUCTION

In a modernized world, science and technology play important parts in culture and affects everyone. This is the starting point by Durant, Evans & Thomas (1989) when investigating the public understanding of science. Furthermore, decision making in society today involve science and should therefore, in compliance with democratic processes, be debated. Also, science itself rests and relies upon public support which is based on public knowledge. This is why we should care. But in a world of many learning opportunities, what stands out as relevant and by whom?

There is a substantial volume of research concerned with secondary students' interest of science and technology. The majority of those studies pay attention to school science. Fewer have presented a picture related to informal settings. In a recent review of students voice in science education, Jenkins (2006) point out that when it comes to what is perceived as being relevant content to learn in school, it is mostly adults perspectives that have had the monopoly. A lot of students in many countries have trouble with apprehending this content as relevant for their lives and personal needs. In addition, there are important similarities between countries in the way young people experience school science (Lyons, 2006). These are some of the reasons why studies into students' perspectives on school science in different countries are important.

The relevance of science education study (ROSE) is the largest research project investigating the students' voice on those issues. One of the results reported from ROSE is that secondary students have interest in science and technology. Their interest is oriented towards specific content, and not towards broad categories like subject areas (Jidesjö et al., 2009) and can be understood as an effect of societal development that have an effect on youth culture (Schreiner, 2006). Schreiner showed this to be the case for many developed countries which imply that there are cultural factors behind questions concerned with students' interest in science and technology. There are more studies pointing in this direction. Baram-Tsabari and Yarden (2005) investigated young people's spontaneous interest in science and technology by analyzing their questions sent to an ‘ask a scientist’ television show in Israel, followed up by a study analyzing children’s questions sent to an ‘ask a scientist’ web site, from several English speaking countries (Baram-Tsabari, Sethi, Bry & Yarden, 2006). In both studies they discuss young people’s interests for science as being strongly influenced by societal development which among other things mean that today you can learn about science in many ways outside school. Young people use media because it is fun and they have grown up with it and there are commercial interests behind as well. By such processes, the way science is treated in educational systems is challenged (Brady & Kumar, 2000; Weigold & Treise, 2004). As several studies are pointing to societal development and the way those circumstances change young people’s out-of-school experiences and thereby what is perceived as relevant to learn, informal science learning is important to investigate in relation to school science learning (Braund & Reiss, 2006).

Science meets public in the media which is the new social contract (Gibbons, 1999). The stories are contextualized by journalists who try to make them intelligible, often in ways that appeal to people's sense of feeling, to entertain and frame but also manipulating. In the case of cloning, which is one example, science is portrayed from science fiction, described in dichotomies and contributes to cultural fears instead of enlightening the public (Huxford, 2000). The way science meet the public on TV in a modern society, is a consequence of political and economical realities but with a keenly alive to customers wants (Cottle, 2004). There are several factors involved in the process from production to reception and the content is affected even before it reaches the press room (Holliman, 2004). Journalists know what attract their users and present their stories with elements that people need to make them purposeful. This of course, has consequences for science citizenship. It is not one single institution that will contribute to a vision of a scientifically literate population (Dhingra, 2006). Media is not only about entertainment. It should be understood as a contributor to young people’s views on science (Ormerod, Rutherford & Wood, 1989). This is not to say that educational settings should try to emulate media. There are evidence of stereotypical sex roles and narrow portrayals of scientists and scientific work (King, 2000). It is more a question of understanding what the development of communication media mean for the experience of science and consequently, what that implies for authentic learning environments (Roth, 1997). Media science and science education can benefit from each other (Salleh, 2001), remembering that the governing body on teacher work are quite differently from ways science knowledge is restricted in other areas (Treagust & Harrison, 2000).

METHODOLOGY AND PURPOSE OF THE STUDY

The purpose of this study descent from two observations. Firstly, several studies concerned with students’ interest for science point out that they have interest for certain contents. Young people seem to be oriented towards a specific substance within those knowledge areas. How can this circumstance be understood? Secondly, many researchers concerned with societal development, culture and modernity related to science education, discuss the need for studies giving an account of media and young people’s experiences due to their development. In a modernized society, is there a possibility that young people’s engagement with science and technology can be understood as a media effect?

The analysis method I have used is founded on results from the ROSE study in Sweden. This empirical data set is part of the international ROSE data reported by Schreiner (2006). Schreiner and Sjøberg (2004) give an account for all details concerning data collection, methodological issues, rationale and underlying ideas in this world wide research project.

The national Swedish data I use have been generated by using the ROSE questionnaire, where 751 students in 2003 in the end of compulsory school have answered 108 questions about ‘what they would like to learn about’ on a four graded Likert scale. The category contained questions concerning astrophysics, earth science, human biology with sex and reproduction, genetics, zoology, botany, chemistry, optics, acoustics, electricity, energy, technology, ‘Science, Technology and Society’ (STS) and ‘Nature of Science’ (NOS). The questions were put in different contexts such as spectacular phenomena, fear, technological ideas and inventions, aesthetical aspects, beauty, care, health, personal use and everyday relevance. The specific topics young people rank as relevant to learn I call a ‘content orientation’ and are much the same for students in the whole modernized part of the world (Schreiner, 2006).

Almost all topics that are part of their content orientation play important parts in science and technology but do not follow the way the traditional school subjects treat the content (Jidesjö et al., 2009). They are like two different content orientations. Young people seem to give precedence to other kind of priorities than the traditional school subjects’ lay stress on. In trying to understand this split, I search for the content orientation that is put forward by the students among other stakeholders that manage science and technology. In this study I have used the method ‘content analysis’ to explore the content that is in charge of one international popular science television channel, i.e. ‘Discovery Channel’ from ‘Discovery Communications LLC’ (2010). All information about ‘Discovery Channel’ was downloaded from the Internet. Because of the space limitations I only present one analysis here from one TV-channel. Then I compare what is broadcast on ‘Discovery Channel’ with the content orientation that is perceived relevant among the teenagers.

RESULTS

In the analysis I have picked out all the programs on ‘Discovery Channel’ that was broadcasted during one week from 1st of March to the 7th of March in Sweden. Among those, seventeen programs were excluded because of lack of good information (Table 1). Besides, many of the programs in Table 1 did not get much time in the programme schedule.

Table 1. Programs on Discovery Channel in Sweden that were excluded from the analysis because of the lack of good information.
Krig på skroten
Street Customs Berlin
Femmans växel Europa
Fiskefantaster
Från vrak till bubbla
Amerikanska hotrods
X-Machines
Factory Made
Gröna åk
Discovery Project Earth
Mega Engineering
Jag borde varit död
Syna bluffen
Fiskeäventyraren
Rally-VM: Bakom ratten
Extrema bilar
Årets värsta tornados

In the next step I put together eighteen programs with good information and that had their international correspondence, which means that they are broadcasted in several countries and reaches an international audience (Table 2). The short descriptions of the programs stems from official wordings on the Internet (Discovery Communications LLC, 2010) and chosen to give a sense of what the programs are about, what kind of questions they answer.

Several of the programs presented in Table 2 are given lots of time in the programme schedule.

Table 2. Programs on 'Discovery Channel' in Sweden with international correspondence presented with short descriptions.

How do they do it?	Just when you thought How Do They Do It? had told you everything you had ever wanted to know, Robert gives us answers to even more questions as he gets his down and dirty in his quest to understand modern technology.
Megabuilders	As the world's engineers and planners come up with new ways to solve the increasing demands of life on Earth in the 21st century, there are many amazing engineering projects taking place globally.
Mythbusters	Jamie and Adam are engineering and construction experts who combine science, special effects and technology to determine the validity of countless popular myths and legends through a series of tests and experiments. Welcome to Mythbusters - home of myths, science, experiments and explosions.
American chopper	Real bikes. Real fights. Real man hugs. This cult series tracks the daily tension, tirades and triumphs of a father and son team, as they run a business creating custom motorbike masterpieces.
How it's made	How articles for everyday use are made.
Miami Ink	Follow tattooists Ami James, Chris Garver, Darren Brass, Chris Nuñez, the glamorous Kat Von D and apprentice Yoji as they go about their business. Miami Ink challenges cultural stereotypes of skin art and illustrates the real talent behind the famed 'inkists'.
Time Warp	MIT scientist and teacher Jeff Lieberman - along with digital-imaging expert Matt Kearney - uses new technologies to bring truly never-before-seen wonders into a form that your body can actually process.
Dirty Jobs	Join Mike Rowe when he experience some of the planet's most dirty and dangerous jobs and meet the courageous people who perform these jobs every day.
Topp tio	For example the ten best fighter aircraft, the ten best tanks…submarines, choppers etc.
Chop Shop	See Bernie, Leepu and the team of master mechanics turn bangers into blingers. Supercars for superactors.
Industrial junkie	Jonny Smith take a closer look at how things are made, from oil drilling to super highway construction.
Born survivor: Bear Grylls	What does it take to be a true survivor? Adventurer Bear Grylls demonstrates in each episode, pushing his body (and gag reflex) to the limit. From skinning camels, eating a live snake and drinking water squeezed from elephant dung to building fires, setting up camp and navigating in the middle of the desert, when it comes to survival, nobody does it quite like Bear.
Huge Moves	Transfer of a big building
Storm Chasers	The latest season brings bigger, badder vehicles, monster hail storms and rivalries with other storm chasing crews. As if that wasn't enough, the team had a dream came true in the season finale, coming closer to a twister than ever before!
Destroyed in Seconds	From tower block implosions to rampaging tornadoes, catastrophic mid-air collisions to sudden terrorist attacks and dangerous races to stolen army vehicles, Destroyed In Seconds is the place for your fix of everything explosive.
Fearless Planet	A look at some of the planet's most amazing creations.
Survivorman	Living off the land takes on a new meaning when wilderness survival expert and filmmaker Les Stroud spends nine harrowing weeks in a variety of survival simulations. He takes off alone and heads to a punishing corner in the back of beyond with nothing but a few cameras to document his (often miserable) experiences
Wheeler Dealers	Video clips, photos and Mike and Edd's top tips on buying used cars. Learn how to restore a classic car to its former glory and get the best advice for buying used cars. Listen to these Wheeler Dealers and you might even be able to make a few quid yourself in the used car game.

In the continued content analysis I use results from the ROSE study in Sweden, presented in Table 3, showing the 20 first topics students want to learn about compared with what program on 'Discovery Channel' they can watch to have their wants stimulated.

Table 3. The 20 first topics in the ROSE questionnaire students want to learn about presented with means in falling order with standard deviation (SD) compared with what programs on 'Discovery Channel' that can be watched to stimulate those topics.

Topics in the ROSE questionnaire	Mean (SD)	Program on 'Discovery Channel'
How to exercise to keep the body fit and strong	3.03 (0.96)	Mythbusters, ***Born survivor: Bear Grylls, Survivorman***
How it feels to be weightless in space	3.00 (1.02)	Mythbusters
The possibility of life outside earth	2.93 (1.05)	
Why we dream while we are sleeping, and what the dreams may mean	2.93 (1.06)	Mythbusters
How different narcotics might affect the body	2.84 (1.00)	Mythbusters, ***Born survivor: Bear Grylls, Survivorman***
How alcohol and tobacco might affect the body	2.83 (0.98)	Mythbusters
What to eat to keep healthy and fit	2.81 (1.02)	Mythbusters, ***Born survivor: Bear Grylls, Survivorman***
What we know about HIV/AIDS and how to control it	2.80 (1.01)	
How to perform first-aid and use basic medical equipment	2.79 (1.00)	Mythbusters
Phenomena that scientists still cannot explain	2.77 (1.12)	Time Warp, ***Megabuilders***
Thought transference, mind-reading, sixth sense, intuition, etc…	2.77 (1.11)	
Sexually transmitted diseases and how to be protected against them.	2.77 (0.97)	
Cancer, what we know and how we can treat it	2.74 (1.03)	
How meteors, comets or asteroids may cause disasters on earth	2.71 (1.04)	***Fearless Planet, Destroyed in Seconds,*** Mythbusters
How my body grows and matures	2.69 (1.00)	
How computers work	2.69 (1.03)	***How do they do it?, How it's made,*** Industrial junkie
Sex and reproduction	2.68 (0.94)	
Black holes, supernovas and other spectacular objects in outer space	2.67 (1.11)	
How to protect endangered species of animals	2.65 (1.02)	
Unsolved mysteries in outer space	2.65 (1.12)	

The results show that many students are interested in questions concerned with diet and health, astronomy and cosmology together with modern technology and challenging diseases. Many of the topics that students are interested to learn about are in compliance with what is televised on 'Discovery Channel'. What are missing to have a full match are more health stories and cosmology.

DISCUSSION

The idea with this study is to put together some of the latest research concerned with students interest of science and technology and consider the matter more closely from a cultural perspective. Maybe, to give expression to students' voices and understand them as utterances of changing experiences due to modernization and globalization, is one important way forward in science education research. This implies an increased comprehension of what changing experiences entail for students' possibilities to learn science and technology when they encounter compulsory school. Even though there are many similarities in developed countries between 'what students want to learn about' and 'what media telecast to satisfy peoples wants' it is not possible with the data presented here to explain the results in a cause-effect relationship. There are several important methodological conditions that may have influenced the results. Yet, only with one single analysis and with simple statistics from the ROSE study, there are congruity between students' wants and media. As this is an ongoing project and kind of new perspectives within science education research, there are more detailed results to present in the future.

The point with this study is to turn the attention to media and specific science content and trying to understand people's engagement with science and technology from ways the content can be experienced outside school. Maybe 'science in society' can assist in understanding students' interest or disinterest for school science (Braund & Reiss, 2006). In this case, 'Discovery Channel' constitutes one example of what parts from science and technology that are brought out and how they are contextualized. Modern technology, how things work, mysteries, wonders, spectacular phenomena, myths and explosions seem to be important. Health issues are not that protruding on this channel as is the case with astronomy. But this is just a look on one channel on one week in Sweden. On the discovery home page there is information that because of NASA's 50th birthday, Discovery Channel is presenting a series of episodes of the space pioneering (Discovery Communications LLC, 2010).

Journalists and program makers present their stories in a way that make people continue reading or not to switch the channel. This is done from a cognizance of production as well as reception (Holliman, 2004). With societal development, several more actors will treat science and technology from the purpose of marketing certain content in narratives that make people want to participate (Dhingra, 2006). I argue that this could be one important factor behind the international similarities in young people's content orientation in modernized countries (Schreiner, 2006). With this study I contribute to this field of research by analyzing specific content and relating to informal science learning. Further studies are needed that pay attention to both formal and informal science learning and what those circumstances means for the experience of school science among youth in different societies. It would also be interesting to continue analyzing and compare with what content is focused in classrooms, curricula and teaching aids.

Students are not talking with one voice (Jenkins, 2006). What I present here is only a broad picture. Questions of ethnicity, gender and age are three examples of interesting continuations. Other methodologies are a second significant perspective. Thirdly, and maybe the most important, is a discussion of the purpose of science and technology as parts of education. I have not said that school science should be like media science. Especially as there is evidence that science in the media sometimes scare people instead of informing (Huxford, 2000). Maybe quite the opposite, school science can benefit from media (Salleh, 2001) and not trying to be in a competitive situation. To prepare people for citizenship should be the main purpose and public function of compulsory education. When science and technology affect everyone's life, it demands on the educational system to be updated and relevant. To handle media, to understand from what purposes stories are told and that many times, there are economical and political realities behind (Cottle, 2004) are of equal importance as learning some science facts. Science in the media is also the way most people will continue encountering those knowledge fields after formal schooling.

Modernization involved a strong development of communication media and can be traced back several hundred years. In spite of this production and the importance of how it affects people's lives, media studies have been marginalized in social science research and there are several reasons for that (Thompson, 2001).Thompson tries to develop a social theory of the media and one of the most important starting points in his account is that communication media are central in modernization and lead to a world where many experiences are mediated and separated from shared meeting places. In addition, there are many different actors who treat content in different stories from various purposes. People will have to sort through this and structure mediated knowledge in what is relevant from a personal point of view. By those processes, meaning making is not a static phenomenon. It is in constant movement and transformation (Thompson, 2001).

To reach people in a modernized world you will have to explain why they should care, anchoring announcements in people's wants and needs. Those are like new rules in the development of communication. In its basic sense, authentic science learning environments are strongly involved in the development of communication media (Roth, 1997) where mediated experiences reshape traditions. To develop learning environments, where products of a civilization can be discussed, reflected and contemplated is important if education should contribute to empowerment, international understanding and piece. The reversed order can be the feeling of being an outsider, which for science on compulsory level today, is true for many students

ABSTRACT

The current paper explores the potential of using a systemic approach to ESD issues within science education in order to acknowledge and integrate their social, cultural, environmental and ethical dimensions in the educational praxis.

A group of undergraduate teacher students was introduced to Sustainable Development concepts emerging from, or related to, the science curriculum through a variety of approaches and contexts and establishing links with their environmental, biological, ethical, social and cultural aspects. Using elements of participatory action research, the students were invited to discuss the systemic approach used, in terms of acquiring a holistic understanding of the concepts, the practical pedagogical value of the systemic approach, as well as any constrains observed during the implementation.

The objective of the paper is to discuss the use of the systemic approach as a means of linking science curriculum concepts with Education for Sustainable Development. Science curriculum can provide a basis – starting point for the study of several SD issues and establish links with other curriculum subjects in a pedagogically beneficial way. A systemic approach will enable the reunification of fragmented information and thinking and can help students understand profoundly and effectively the interrelations and interactions between SD issues and concepts.

Keywords: *Systemic approach, education for sustainable development, science education, sustainable development issues, programme development*

INTRODUCTION

Education for Sustainable Development emerged from Environmental Education but constitutes and embraces far more than its origin. Sustainable Development being at its centre, ESD engages in highlighting the links between environmental, social and economic issues, and expands on values-oriented issues such as democracy, social equity, peace, human rights and health. It focuses on (a) learning about the environment and its operation; (b) understanding the impact the environment receives from social, economic and developmental activities; (c) realising the environmental degradation; (d) considering sustainable approaches and solutions that can lead to its sustainable use as well as (e) developing skills and abilities for acquiring this knowledge. ESD also uses the environment as a “learning environment” for raising awareness and developing emotional ties that can turn individuals’ attitudes and actions towards sustainable life styles. Individuals are empowered so as to become carriers of this change and gatekeepers of a sustainable use of the natural resources in democratic and sustainable societies. It therefore constitutes a revolutionary form of education both in terms of content and implementation.

ESD is founded on critical and innovative thinking that can emerge in any context, any place or moment and promotes change and social and educational restructure. It supports social and ecological solidarity, social justice, responsibility, tolerance, and according to these values it processes sustainable development issues, man – nature relations and interactions and promotes democratic social changes through critical and participatory approaches (Flogaiti 2006).

The critical role of ESD as the means for promoting SD has been prompted by various conferences and official documents, for improving the capacity of people to address environmental and development issues (UNCED, 1992; UNESCO, 2002). The UNESCO Decade of Education for Sustainable Development seeks to achieve through education, a world where everyone has the opportunity to benefit from education, and acquire the values, behaviour and lifestyles required for a sustainable future and for positive societal transformation (UNESCO 2004, p.4).

Science education has an important role to play in education for sustainable development. When it comes to sustainable development concepts, traditionally perceived and treated as scientific, establishing links within disciplines is of even greater importance for the achievement of the global, holistic perspective of SD issues. Issues such as energy, biodiversity or water, form a traditional part of the science curriculum (Mueller M.P. and Bentley M.L., 2009). Students are often introduced to these issues through inquiry, scientific processes, skills acquisition and they learn about their content, their properties and related phenomena. Nevertheless these issues also need to be linked to social, cultural, economic and environmental implications or causes (Barret E.S. and Pedretti E. 2006). Science teachers consider that although their teaching can contribute the important knowledge and abilities required for ESD, it is not their role to inculcate in their students behaviour, attitudes or values (Gayford 2002). There is also an underlying concern that linking science to ESD might endanger the integrity of science education.

The common ground with ESD provides a unique opportunity for Science education, to take advantage of the ESD qualities that can enable the establishment of links with the social, cultural, environmental and ethical context. The synergy between science education and ESD can work in a way that can benefit both; it can enable the achievement of latent goals in science education and can provide a starting point for introducing ESD issues in the curriculum.

Due to the school organization and operation, primary education can easily facilitate the systemic, holistic and consequently integrative approach to SD and scientific issues. Primary schools are flexible in their programme and the teachers have the potential for distributing SD issues in the curriculum and establishing the required links. The existing flexibility of primary education for organizing and coordinating the integration of SD within the curriculum, eliminates any concerns for demotion of any discipline and contrary to that it contributes to their enhancement. This integration is nevertheless demanding for teachers, who feel more confident following the traditional educational schemas. Discipline oriented education received by teachers, impedes the acquisition of crosscurricular integration skills (Moslemi. J, Capps K., Johnson M., Maul J., McIndyre P, Melvin A., Vadas T., Vallano D, Watkins J. and Weiss M. 2009) and probably constitutes a gap in teacher education. It also reinforces the continuation of the segmented cognition and skills acquisition and limits a creative, critical, systemic way of thinking. Strict fragmentation of the disciplines and the boundaries between sciences, have also impeded the integration of ESD in the teachers' programmes of study. Despite the UNESCO (2004) recommendations about reorienting teacher education towards ESD as a key strategy in achieving a sustainable society, ESD is far from becoming mainstream and it is rarely addressed during initial teacher education.

Nevertheless teacher students, as future teachers, are expected to develop and deliver ESD through primary education curriculum in a holistic – cross curricular way and highlight the systemic character of SD issues. They will be asked to identify the scientific, social, cultural, environmental and ethical dimensions of the SD issues and effectively re-establish the links that will assemble the greater picture. Yet, it is highly unlikely that their subject oriented teacher education experiences have enabled them to do so.

The systemic approach is a new trend of thought, with an unspecified breadth. It does not suggest a new body of knowledge but it seeks restructuring the organization and operation of our intellectual activity. It is an inherent element of education for sustainable development due to the complexity and multiplicity of the issues it engages with.

The Systemic Approach derives from a "non-analytical" way of thinking. The Analytical way of thinking lead to a compartmentalisation of knowledge and studied in depth the "section" and ignored the whole. This approach ignored the interconnections of the parts and the additional properties attributed to a system due to these connections and entailed the risk of drawing erroneous or inadequate conclusions. The development of individual scientific areas was based on this way of thinking. The non-analytical approach accepts that reality emerges from the interconnectedness and interactions rather than the isolation (Stranga 2006).

Systemic thinking is the way of approaching the "whole". It enables the learner to obtain a better understanding of the connections rather than the sections and recognise change and evolution over stagnation. The learner identifies the different dimensions and elements of the issue, highlights the relations and interactions of these elements, distinguishes their emerging properties and can analyse their meaning and importance within the structure and dynamics of the system they compose (Flogaiti 2006). As an approach to education, the systemic approach is slow but it has a lasting impact (Benedict, 1999). Therefore the systemic approach can lead to the "transition from *first-order changes* that are superficial and short term to the *second-order changes* that affect the culture and structure of the schools and are slow but long term" (Fullan and Stiegelbauer 2001). The systemic approach therefore holds the potential of enabling the achievement of change as this is sought by ESD.

Besides being a key characteristic of ESD, systemic thinking is a valuable approach to science education since it can facilitate the achievement of objectives that are overlooked by a purely scientific approach. Science education embraces beyond scientific literacy, goals that promote sociopolitical, civic and democratic competencies as well as ethical purposes (Yoon, 2008). Nevertheless education is currently segmented within disciplinary lines and each discipline has its own paradigms, quality standards and vocabulary (Benedict 1999). Linking the context of science concepts to their social, economic, environmental as well as ethical and cultural dimensions is a science education goal that is rarely acknowledged and often overlooked, since these goals are attributed to social sciences (Huges 2000).

RATIONALE OF THE RESEARCH

Our hypothesis was that using the scientific context of ESD issues as a starting point, students could continue their study of the same issues through different perspectives: environmental, social, ethical, economic and cultural. Therefore students would be introduced to the systemic, holistic approach of these issues and acquire practical pedagogical experiences and skills that would raise their self efficacy for integrating ESD issues in the curriculum and becoming able to link science to its marginalised goals and qualities.

The research was developed as part of the self evaluation process of a new optional module offered to third year undergraduate teacher students. Additionally it addresses issues concerning the potential use of the systemic approach in highlighting the links between the science curriculum and ESD.

PURPOSE OF THE RESEARCH

The general purpose of the research is to examine the potential of the systemic approach for linking science education concepts to their non-science oriented context. This is achieved through exploring students' perceptions about the systemic approach, science education, education for sustainable development and the perceived connections between the three. The research also examines students opinions about the difficulties posed by this approach and also seeks to identify the benefits that the students see in the systemic approach. Students' self efficacy for a systemic - integrated approach to ESD is also examined.

The research questions addressed were:

(1) How do students understand the systemic approach and its educational value with respect to science education and ESD?
(2) How do students perceive the connection between ESD, Science education and the systemic approach?
(3) Which practical implications arise from the use of the systemic approach in the teaching process, for linking science education to ESD issues?
(4) Which is students' self efficacy in using the systemic approach in the context of ESD and science education and how can it be enhanced?

METHODS

The educational intervention - The module

The module was an optional module, specialising on ESD and Science Education. It was designed in order to help students acquire a systemic way of thinking, realise the interrelations and interactions between scientific, social, cultural, environmental and economic aspects of SD issues within the science curriculum and develop the skills that would be needed in order to develop and deliver ESD and science education concepts in schools, in a systemic integrative way.

Its objectives and outline were set by the instructor, but students were invited to participate in its development by providing feedback about the theory, the concepts and the methodology of the module's delivery. Students had already attended two science education modules and two environmental education modules.

The ESD and Science optional module started with informative meetings on ESD and introduction to science education in order to refresh and ensure the existence of the basic required knowledge. They were also introduced to systems thinking and the use of the systemic approach in teaching.

Theory was put into practice when students engaged in the study of a number of science / SD concepts through a systemic design and holistic approach (energy, water, biodiversity). Based on constructivism theory, each unit begun with brain storming and concept mapping techniques in order to reveal students' existing ideas and thinking biases about the concept. This process was later on reviewed and elaborated in order to constitute the basis for the development of the lessons that followed. Additionally to the scientific approaches used for the study of the concepts (inquiry, explorations, scientific processes), other pedagogical activities were used (role play, debate etc) in order to establish the sought connections with social, cultural, environmental and economic, aspects of the issues, and draw from a variety of disciplines; arts, humanities and social sciences.

The module delivery was completed in January 2010 and research was conducted after the end of the examination period so as not to pose ethical issues concerning students' evaluation and enable a more objective and sincere participation in the research.

The sample

The group of students attending the optional lesson, was small (8 students), which was approximately one third of the third year students' population. This is due to a transitional period of departmental transfer to a different campus. All the students attending the module were invited to participate to the interviews and six of them accepted the invitation.

The instrument

The interviews were conducted by a trained thesis student in order to avoid the instructors' – researchers' involvement as this was likely to influence the way the students would respond to the questions. The use of a structured interviews protocol was considered to be suitable for our circumstances, since it would be easier for the student - interviewer to conduct. The interviews were conducted anonymously and followed a pre-structured protocol, which is included in the appendixes of the paper. During interviews students had the opportunity to discuss their experience of the lessons. They were asked to express their opinion on the module development processes, the teaching techniques used, the benefits and drawbacks they observed and finally to offer their suggestions for the improvement of the module and discuss their self efficacy for putting what they learned (information and pedagogical skills) into practice.

The analysis

Interviews transcripts were qualitatively processed by means of document review and analysis. During the review, we considered the answers to each protocol question. Some of these answers were synthesised in order to form the broader categories which are discussed in the results part.

Limitations of the research

We acknowledge that the sample participating in the research was small, nevertheless this was due to the limited number of the overall 3rd year student population. This group was the 1st group to attend the new module and therefore were the only ones eligible to participate in the research. In-depth interviews and the use of qualitative analysis was the most appropriate research approach due to the existing conditions and limitations. Therefore we have to acknowledge that the outcomes of our research can by no means be generalised. They will be useful for the educators and programme developers for the improvement and possible modification of the module offered and can form the basis for future research.

RESULTS

Students' understanding of the systemic approach and its educational value

Overall, the students appeared to have acquired a good understanding of the concept "systemic" as they were able to define and explain it. They considered that "in education, the systemic approach is a methodological approach, through which individual parts of a system as well as their interrelations and interactions are studied in order to acquire an understanding of the whole". Through the explanations given, it was evident that students' perceptions on the systemic approach connected it to the integrative cross-curricular approach, due to the reunification of a number of disciplines.

Its educational value was acknowledged by all students, although they did not identify or argue about the same benefits. One of the students considered problem solving skills, a benefit resulting from the use of the systemic approach. The same student, argued that the systemic approach can help pupils acquire a synthetic way of thinking by being able to draw information from a variety of disciplines and critically process the collected data. According to students' opinion the established links between disciplines can also enable learners understand practical, real life implications of the concepts under study

Students' understanding of the connection between Systemic Approach, ESD and Science Education

Students acknowledge that the systemic approach can help learners acquire a holistic understanding of natural phenomena and environmental issues. The identification of the different dimensions and elements that constitute an issue, and the examination of the interactions and the collective and individual properties of the parts, can highlight its meaning and importance. They also consider that systemic approach is valuable for science education as it enables the collection and organisation of knowledge and can lead to solutions for the scientific problems of modern life. The fact that systemic approach established links with the social implications of scientific issues was considered an additional benefit for science education. Further on the holistic context might be more appealing for pupils. Finally students discussed that the potential of the Systemic Approach for establishing connections to real life situations can better attract pupils' attention and can link teaching and learning process to students' personal experiences and interests.

The same benefits were acknowledged for ESD. Nevertheless, for some of the students the systemic approach could also result to raising awareness and environmental sensitivity although this attribute was not acknowledged as a benefit for science education. Awareness raising and values development was attributed to the engagement with other disciplines for the systemic examination of the taught concepts.

Implementation Difficulties

The systemic approach was apparently a concept difficult to assimilate, both in terms of context as well as a pedagogical approach. Its practical use in teaching specific concepts during the module delivery was the key to enabling the students understand what the systemic approach was about.

One of the students identified that within the Systemic approach underlies the risk of becoming superficial in approaching any concept. Broadness was considered to put at risk detail and depth. As the same student pointed out an effective use of the systemic approach requires teachers who are trained in a wide range of disciplines and equipped with a wide range of pedagogical skills. This was considered to be essential in order to provide detailed and accurate instruction as well as link all the aspects of the concepts studied.

The organisation and coordination of the “parts” was also mentioned as one of the identified implementation difficulties. Consequent to the systemic approach, the integrative approach, appears to be a complex quest for the students; they express multiple reservations concerning extracurricular activities and pedagogical skills, a demanding curriculum work load and as a result the limitations in time. They consider that in many cases, the systemic approach, results to engaging into extracurricular issues and activities which can indeed enhance the current curriculum but simultaneously can impose additional workload to the teachers and diminish the time available for implementing the official curriculum.

How can students’ self efficacy be reinforced?

Although students did not feel incompetent for using the systemic approach for teaching and learning, they neither appeared to feel too competent using it. They acknowledged the pedagogical value of the systemic approach but some of them were still unsure about its use. One of the students explicitly expressed the need to develop a clearer understanding of the planning and implementation process. The use of the approach by the trainer, for the delivery of science education SD concepts was considered to be very useful as it set an example for the students and helped them understand the planning and implementation process. Still students seemed to be in need for more such pedagogical experiences.

Students appreciated most, the activities which enabled them to engage in practical teaching in the classroom. The familiar and friendly classroom environment, with their peers, was considered to be ideal for planning and teaching small lessons on SD concepts following the systemic approach. The interaction with their peers and the discussion of the delivered classes offered them valuable feedback.

Students commented that all stages followed within the module were necessary, followed a rational time sequence and helped them understand the approach, its educational value, the process to be followed for the planning and finally the organisation and delivery of the classes. They requested more practical activities and more opportunities for microteaching, although they could not cancel or restrict any of the module's elements.

DISCUSSION

Environmental degradation and the promotion of ESD for the development of sustainable lifestyles have created a growing need for scientists who have the skills and expertise to tackle the enormous complexity of contemporary environmental problems. The development of such scientists requires training that cuts across traditional disciplinary and methodological lines (Moslemi, *et al*. 2009) and has implications for teacher education (Martin, Brannigan and Hall, 2005). In the case of teacher education, there is an apparent need for reconsidering the programmes offered (UNESCO 2004).

Initial teacher education provides a clear view of the content and pedagogy of individual disciplines raising students' efficacy to teach the respective curriculum lessons (Intrador, 2006). It is nevertheless inadequate when it comes to delivering integrative educational innovations such as ESD and this, results to a limited self efficacy of the teachers to implement ESD in schools.

Within teacher education programmes, Science Education is the discipline with the most obvious connections to ESD, (apart form any specialized ESD modules) and in many cases it is the only available discipline that can contribute to ESD. Nevertheless, teacher students and teachers, as indicated by research (Gayford 2002) have difficulty in connecting science education to the social – ethical – awareness raising aspects required by ESD. The moment these links are established, the lesson is no longer perceived as science education but some area of social sciences. Science teachers need to find ways of maintaining the integrity of their chosen discipline and at the same time contribute to ESD. Although this is not an issue within primary education, it is raised as a major issue in teacher education.

Reorienting teacher education towards an integrative programme of studies poses practical limitations and holds the risk for superficial instruction, with coordination difficulties. Even aligning subjects or disciplines in parallel schedules or units does not necessarily offer integrative experiences to the students (Thompson–Klein 2005). Simultaneously solid knowledge in the various scientific fields is a key objective of teacher education so as to produce competent educators. Taking these as facts, how can teacher education produce the multi-skilled scientists needed for ESD?

Enhancing collaboration and integration of knowledge across traditional disciplines has been often discussed (Martin et al., 2005; Paige, Lloyd and Chartres, 2008) and it would be interesting to explore the extent this could take within teacher education programmes. Nevertheless, we have to acknowledge the practical hindering factors and limitations of such an approach within higher education. Research outcomes indicate (a) the need for training the trainers; (b) the existing need for safeguarding ones' disciplinary territory; (Gayford 2002) (c) the need of higher education for in depth learning as opposed to superficial learning; (d) coordination difficulties; (e) discipline priority and marginalisation of ESD; (f) accreditation difficulties (Martin et al., 2005). One of the possible solutions of bridging this gap in teacher education is the establishment and provision of integrative modules that can enhance and reinforce the students' skills so as to be able as future teachers to establish transdisciplinary links to ESD.

Our research considered the potential of science education for opening the gates for ESD and exploited the systemic approach as a common approach that could link science education to ESD. Starting with the scientific context of ESD concepts, the systemic approach facilitated the connection to social, cultural and ethical implications which are not perceived as relevant to science education and assisted the achievement of latent goals of science education. Further on it offered opportunities for engaging in pedagogical and methodological approaches that differ to the ones frequently adopted by science teachers (Gayford 2002), enhancing therefore teacher students' pedagogical skills and abilities. Despite their contact with the approach and the understanding they developed concerning its context, its practical use and value, students still expressed reservations about its use in primary education. These reservations concerning the systemic approach can be anticipated and justified if we consider that teacher students are still developing their pedagogical skills, learning to manage time, organise and manage the classroom, becoming familiar with the use of methodological approaches and building up content knowledge on a number of disciplines (Luft 2007).

Microteaching activities, engaging students in practical teaching, were commented to have positive impact on students' self efficacy. Nevertheless students stressed the need for more such opportunities. This outcome has implications concerning teacher training programmes' ability to provide practical teaching skills through real experiences with respect to the structure of the modules taught as well as students' opportunities for teaching practice in schools. It would be interesting, in future research to explore students experience of lessons elaborating ESD concepts in a systemic way in schools and the opportunities they have to teach ESD / science concepts using the same approach.

Implications and challenges for the future

We have to acknowledge that the outcomes of the research can have practical use only for the improvement and revision of the specific module. Nevertheless results are relevant to teacher education in general, science education and ESD. The use of the systemic approach as a vehicle that can link ESD to curriculum disciplines and enable the creation and delivery of integrative modules seems to be promising and beneficial for promoting ESD within teacher education programmes and enhancing science education. Future research can scrutinise the potential of integrative ESD modules for enhancing teacher students' pedagogical skills and methodological abilities and raising their self efficacy in ESD and explore possibilities for augmenting the number of opportunities for experiencing and practicing teaching ESD during teacher education.

ACKNOWLEDGEMENTS

We would like to thank the SPE304 students for their enthusiastic participation in this research.

APPENDIX A

The interviews protocol

1. Please explain what you understand about the term systemic approach.

2. Which is your opinion of the educational value of the systemic approach?

   (a) extremely worthless, (b) worthless, (c) neither valuable nor worthless, (d) valuable, (e) extremely valuable

3. In which of its attributes do you identify its pedagogical value? (What does the systemic approach offer to education?)

4. What does the systemic approach offer to science education?

5. What does the systemic approach offer to education for the environment and sustainable development?

6. Which difficulties could arise during the use of the systemic approach in school?

7. In which degree did you use this approach in order to plan and deliver the lessons for the microteaching? (1: approach was not used, 2: limited use, 3: slightly used, 4: very used, 5: extremely used) Describe how you worked.

8. Discuss your experience in the class. Which aspects of the module you found difficult, and which aspects benefited you the most?

9. Would you use this approach at school? How competent do you feel to do so? (1: Extremely incompetent, 2: incompetent, 3: neither competent, nor incompetent, 4: competent, 5: extremely competent). Why?

10. What do you think about the way that you were introduced to the concept of systemic thinking and systemic approach?

11. Is there something that you would like to change? What? In which way?

12. What is you opinion about the methodology used during the module, in order to enable you to use the systemic approach in teaching scientific and ESD concepts?

13. Is there something that you would like to change? What? In which way?

UNDERSTANDING OF DC-CIRCUIT PHENOMENA IN DIFFERENT AGES

ABSTRACT

The aim of this cross sectional pilot study is to analyse the development of external representations of DC-circuit phenomena by interviewing 3rd, 6th and 9th graders at Finnish compulsory school. The study is a national level preliminary study of an international research project in learning DC-circuit phenomena. The project aims at producing comparable and generalisable information on the development of students' external representations of DC-circuit phenomena, and their learning processes in the domain. This study aims to offer information for the design of a novel tool and method for analysing the development of external representations of DC-circuit phenomena.

Earlier studies have reported difficulties in understanding this abstract topic. The learning difficulties typically occur in the qualitative understanding of DC-circuit phenomena. According to earlier studies, although pupils can solve quantitative problems, they do not understand how circuits function qualitatively, nor can they apply the learned concepts to a concrete circuit. However, it has been reported that the external representations evolve in relation to given instructions, and the age of the pupil; the older the pupils are, the more scientific are their representations.

According to the results of this study, development occurs in the external representations of DC-circuit phenomena. Surprisingly, the interviews with the 6th graders proved to be the most fruitful. Moreover, it is surprising that all age groups seem to understand more qualitatively the functioning of the electric circuits than reported earlier. Their external representations include correct fragments of different DC-circuit connections.

Keywords: *learning process of DC-circuit phenomena, age, and instruction.*

INTRODUCTION

Understanding the DC-circuit phenomenon has been found to be difficult and abstract for pupils (Gunstone et al. 2009; Mulhall et al. 2001). Many researchers, like McDermott and Shaffer (1992) have reported that pupils of varying ages have problems in understanding DC-circuit concepts or working with electric circuits. The learning problems typically occur in the qualitative stage of DC-circuit phenomena. Although pupils can solve quantitative problems, they do not understand how circuits function qualitatively, or what the influence of different components is on the source voltage, and the electric current. Nor can they apply the learned concepts to a concrete circuit. In this study, the research question was set as follows: How does pupil's external representations of DC-circuit phenomena develop in relation to her/his age, and given instructions in Finnish compulsory school?

This research is a national level preliminary study of an international joint research project. The next step is the development of a novel analysis tool, and method that will be used to study how the external representations of DC-circuit phenomena develop in compulsory education.

PUPILS' EXTERNAL REPRESENTATIONS OF DC-CIRCUIT PHENOMENA

The extensive research literature discussing conceptual understanding and learning of DC-circuit phenomena has revealed pupils' external representations of DC-circuit phenomena. The term "internal representation" instead of "mental model" has been used recently to better describe pupils' tentative phase of modelling. In proportion the use of "external representation" has become general. In this study, the term external representation is used because it better describes the tentative nature of these models (Gilbert, Justi and Ferreira 2007).

The representations have been concerned with DC-circuit phenomena and the concepts of the electric current, the source voltage, and the electric circuit. For example, in Shipstone's (1984) study, it was found that the main misunderstanding in the pupils' representations was the nature of the electric current: Is there one or two opposite electric currents? Where does the electric current come from? Is the electric current consumed or conserved in the circuit? How does the structure of the circuit affect the electric circuit? Is the electric current some kind of material? Moreover, the students have difficulties in understanding the bipolarity of the components, and the role of the wire: Is only one wire from the battery enough? Why does the bulb glow? What happens in the wire when the bulb glows? The role of the battery varies: Is it a source of a constant electric current? Where does the electric current come from? What is the relation between the electric current and the source voltage?

According to Borges and Gilbert (1999), the external representations evolve in a commensurate manner with the instructions given to the subjects. Also Cosgrove et al.'s (1985) study showed that the external representations evolved in relation to the age of the pupil; the older the pupils, the more scientific their representations were. This correlation between age and quality of the representations seems natural, and it appears also in Borges' and Gilbert's (1999) models. The age–representation relationship includes the level of instruction because in both studies the subjects were taught in physics. In earlier studies the external representations of DC-circuit phenomena have been studied among different age groups. For example Cosgrove et al.'s (1985, 249) study examined 10–18-year-olds' external representations of circuit phenomena, Tsai et al.'s (2007) 13–16-year-olds', and Kallunki's (2009) 9-year-olds'. In the present study, the particular focus is on the development of the external representations of DC-circuit phenomena.

METHODS

Cross sectional qualitative study with the target group of students from 3rd, 6th and 9th grades of Finnish comprehensive school was executed in May 2009. The pupils were 9, 12 and 15-year-olds at the time. These particular grades were selected because electric circuits are taught in these grades. The data for this pilot study was gathered by interviewing two pupils from each of these three age groups. The number of pupils was limited to six because of the preliminary nature of the study. It was assumed that this number of pupils offer enough information for the further development of the preliminary analysis tool and method. The pupils were selected by the teacher, and the teacher was asked to select students achieving median grades in science.

The interviews were based on pictures of electric circuits, and pupils were asked to explain different situations. The interview protocol was developed in collaboration with an international research team, and it was based on Chiu and Lin's (2005) study. In the interview protocol, for example, a picture was used to describe a situation, where one battery and one bulb were connected with two wires. Then the students were asked: "What happens if another battery is coupled in series with the first battery?" The students were also asked to draw a new figure, and then give arguments for their statements. The interviews were transcribed and analysed using theory driven content analysis.

RESULTS

The results showed that there does occur development in the external representations of DC-circuit phenomena through the level instruction and maturation of the students. The development of the external representations of the electric circuit, the electric current, and the source voltage will be described here in detail. Firstly, the external representations of each age group will be presented with so-called fragment maps (see Figure 1, Figure 2 and Figure 3), which uncover the developing fragments of the main concepts. Secondly, the fragment maps will be compared in proportion to age group. In these maps the fragments of the electric circuit are marked by circular boxes, the fragments of the electric current by pentagons, and the fragments of the source voltage by diamond patterns. As mentioned above, two pupils from every each group were interviewed. So, in the fragment maps the united opinions of the two pupils are marked by compound lines. In proportion, the conceptions that only the other pupil has expressed are marked by dash lines.

GENERAL RESULTS

The general view of the external representations of DC-circuit phenomena among interviewed pupils is that they seem to understand the functions of the electric circuit surprisingly well. Against the reported difficulties in learning about electricity, the interviewed pupils were able to explain and predict qualitatively different situations of DC-circuits. Moreover, the explanations given were more empirically based than theoretically based, which means that learning was clearly experimentally oriented. This finding encourages in developing similar research method to uncover real learning (see Figure 1, Figure 2 and Figure 3).

EXTERNAL REPRESENTATIONS OF 3RD GRADERS

The youngest age group of this study was the 3rd graders. The pupils said in the interview that they had constructed electric circuits in the handicraft lessons. Otherwise they had not been taught DC-circuit phenomena yet. The most divergent thing in the fragment map (see Figure 1) of third graders is that it does not yet have so many different fragments. The five fragments describe an open electric circuit, where only one wire is needed. The light from the bulbs is understood as an effect phenomenon of electricity.

According to 3d graders, the brightness of the bulb depends on the electric circuit. If there are two "own" wires for each bulb, they all shine equally brightly. In practice this means connecting the bulbs in parallel. Using the same logic the bulbs in series shine dimmer. It is interesting that in this phase the explanation is purely empirical or technical instead of generally reported theoretical explanation.

In the case of fragments of voltage, the third graders have a similar conception of the origin of electricity with both the 6th and the 9th graders. In all age groups the battery was described as the source of electricity or energy that flows to the bulbs.

Generally speaking, the fragment map of the 3rd graders is the most unambiguous: the two pupils share all except one of the five fragments.

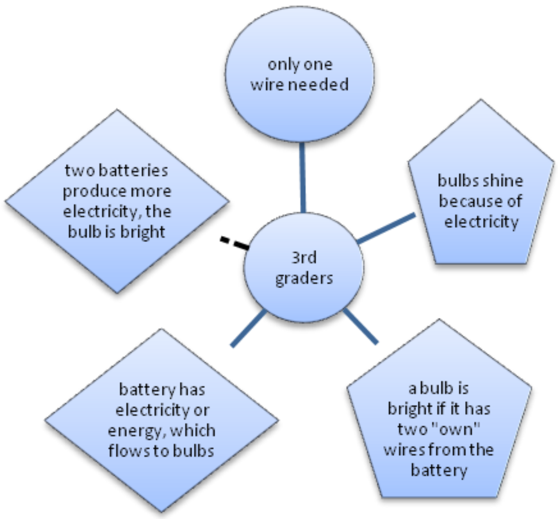

Figure 1 The external representations of 3rd graders of DC-circuit phenomena.

EXTERNAL REPRESENTATIONS OF 6TH GRADERS

The interviews were done in the late spring, just before the end of the spring term. Accordingly, the two interviewed 6th graders had learnt everything what is supposed to be learnt in lower classes. Compared to the 3rd graders' map, there are more fragments in the 6th graders' map (see Figure 2). The electric circuit is almost complete, and only very strictly speaking, there is a minor lack in the circuit. Namely, the structure of the bulb as a part of the electric circuit is still unclear.

As a new fragment the 6th graders suggested conductivity as the explanation for the lighting of several bulbs in series. They also described the movement of electricity using the expression "circulation". As in the 3rd graders fragments, also the 6th suggested the need of two "own" wires for several bulbs in series to produce as bright light as with a single bulb. However, there also appeared to be a conception of electricity consumption as the reason for dimmer lights.

The earlier developed fragment of the battery as a source of electricity had evolved. Both pupils described that the battery has special power. They had a clear picture that batteries in series brighten the bulb. The other pupil even understood the light of the bulb as a measurement of the source voltage.

Although there were more differences between conceptions of the two 6th graders than in the younger age group, the general view of DC-circuit phenomena seems to be quite well-balanced and empirically based.

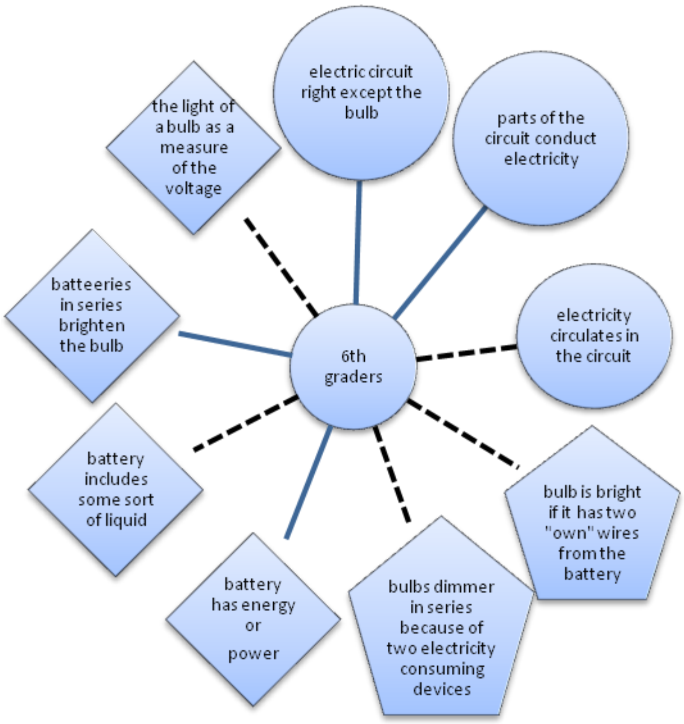

Figure 2 The external representations of sixth graders of DC-circuit phenomena.

EXTERNAL REPRESENTATIONS OF 9TH GRADERS

The fragment map of the 9th graders (see Figure 3) represents the level of concept formation of DC-circuit phenomena after the comprehensive school in Finland. The general view of the map shows that there is more scattering in the development than in the younger age groups. For example, the fragment “connecting bulbs in series is not possible” is quite undeveloped, where as the fragment “the number of batteries as measure of voltage” is well-developed.

There are also other developed fragments. For the first time, the electric circuit is comprehended fully as interview with the other 9th grader shows. The 9th graders still have the conception that the electric current is divided between the bulbs in series. Surprisingly, term “electric current” was used for first time in the interviews with the 9th graders.

The earlier reported electricity–energy–power property of the battery had evolved into voltage. At this phase, the other 9th grader even had a clear picture of the number of batteries as a measurement of the source voltage.

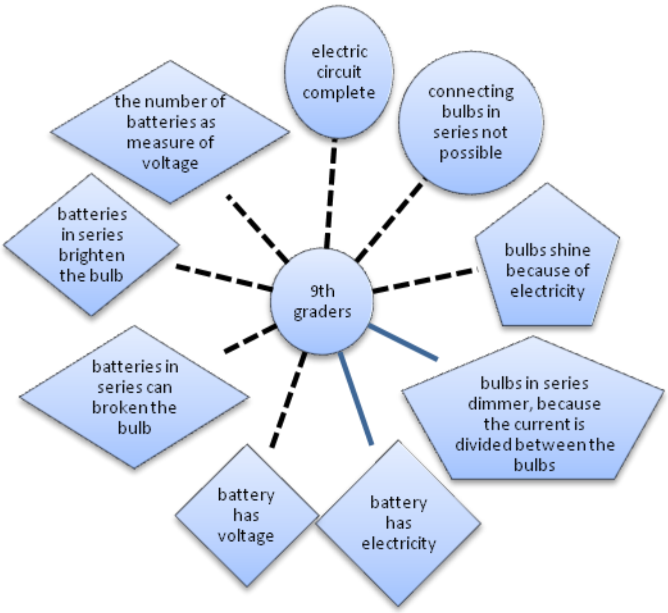

Figure 3 The external representations of ninth graders of DC-circuit phenomena.

CONCLUSION

The results of the study challenge the results of previous research into the abstractness and difficulty of electricity concepts. According to this research, the external representations of DC-circuit phenomena clearly developed along with the level of instruction and maturation of pupils. Surprisingly, the interviews of the 6th graders proved to be the most fruitful. Furthermore, the fragment maps uncover that although the theoretical explanations of DC-circuit phenomena, which have been obtained as results of typical mental model studies, remain undeveloped, learning at the qualitative level of understanding does take place.

This national level preliminary partner study as a part of an international joint research project gives some background data for developing a novel method for analysing how pupils' understanding of electric circuit develops. The next step will be to use diagrams similar to what cladists use (cladograms). The diagrams will show the development of the students' external representations of DC-circuit phenomena, and their learning processes in the domain in a similar way as cladograms represent the evolutionary tree of life.

ABSTRACT

Education is one of the many application fields in which the Repertory Grid Technique (RGT) is employed. It is used in order to determine what students learn, and more importantly, how they learn. This study made utilize the RGT as an alternative evaluation tool to reveal the cognitive structures of the students about direct current circuits and conflicting ideas. “Rating” method was employed for data gathering, which was necessary to construct the repertory grids. The research was conducted with the physics teacher candidate. 10 elements related to direct current circuits were selected and these elements were translated into physical grids that the students could comprehend by the researcher. The participants were asked to fill in the grid by means of rating from 1 to 5. The computer program named GRIDSUITE and qualitative methods were followed in the analysis of the participant grid. It was found out that the RGT provides detailed information about the concepts. It was concluded that the repertory grid is a practical conceptual evaluation tool for direct current circuit. It is concluded that RGT is a convenient tool in assessing declarative and procedural knowledge in science education.

Keywords: *Repertory Grid Technique, concept image, direct current circuits.*

INTRODUCTION

The lack of satisfactory provision of novel ideas to students causes the development of conflicting ideas during their cognitive development period. This might result in conflicts between new and old ideas, which would then become an obstacle against effective learning. Thus, it is crucial for efficient education to detect the concept images and the conflicting ideas of the students.

Despite the inefficiency of the classical measurement and evaluation techniques in obtaining concept images, application of the techniques originally employed in psychology for education enhanced our perspective and measurement capability largely. One of them is the Repertory Grid Technique. Promoted (RGT) originally by Kelly (1955), this technique is employed to reveal the concept images of people.

Constructs, as the concepts they reflect, represent a dynamic system that displays the conceptual changes of an individual (Shaw and Gaines, 1993). This approach is a research method suggested to study the students’ conceptions and conceptual changes. This technique refers to both nomothetic and idiographic concerns (Wandersee, Mintzes and Novak, 1994). Using an approach based on the Repertory Grid Technique might serve as a tool in evaluating the evolution of the conceptual framework of an individual about a certain field.

Education is one of the several fields in which repertory grid is utilized. It is employed to determine what the students learn, and more significantly, how they learn (Jankowicz, 2004). The RGT is efficient in revealing the concept image used to define the whole cognitive structure related to the concepts (Aztekin, 2003).

The Repertory Grid technique could prove to be useful in investigating whether the thoughts of students are conflicting or coherent. In a study on the science concepts of students, Fetherstonhaugh (1994) used the RGT to examine the thoughts of high school students on different energy types. It was seen that the method was successful in revealing the width and depth of the opinions and relationships between them. Moreover, in their study on force and motion, Winer and Abend (1995) found out that the Repertory Grid was effective in monitoring the conceptual change among the high school students. Aztekin, Arikan and Sriraman (2010) propose repertory grid methodology as a way of capturing the constructs of students and argue that this methodology can help us to learn further details about the understanding of infinity.

AIM OF THE STUDY

This study sought to determine the concept images about short circuit, electrical potential difference, current, and the related perceptions, misconceptions, and pseudo-concepts. In addition, it aimed to contribute to determining the educational interest which is necessary to overcome the difficulties that students face in electricity topics. Moreover, the results would be useful to evaluate the RGT since the RGT is used to reveal the structures related to electricity.

METHOD AND PROCEDURE

Examining the RGT and applying it to the topic of electricity of physics class, this study used qualitative research methods and the computer program GRIDSUIT.

There are two ways of determining constructs in the RGT. The most common one is comparing two elements selected from the list of elements related to the topic to observe the similarities and differences, and determining with what construct it would be integrated. On the other hand, the second method asks the participants only to compare and contrast two elements. In both cases, the result is a 2-pole construct indicated by one of the two compared elements. The present study used the latter. The researcher chose the structures in order to examine especially the concepts of short circuit, electrical potential difference and current.

PARTICIPANTS IN THE STUDY

The research was conducted with a physics candidate teacher. The participant has just completed the 5-year undergraduate program of physics teaching at faculty of education.

THE REPERTORY GRID TECHNIQUE

Personal Construct Psychology is an individual and group psychosocial process theory, used extensively in modeling the cognitive processes of humans. Personal constructs are the basic units of the theory of personality, formally presented as a whole in The Psychology of Personal Constructs (1955) by George Kelly, a clinical psychologist who lived between 1905 and 1967. This work is a two-volume book that defines Personal Construct Psychology. Kelly used the RGT in this book. This grid is a matrix composed of elements and constructs, which is compiled by the participants by means of rating. The elements could be persons, institutions, objects, thoughts or events, whereas the constructs express the similarity, contrast and the relation between the elements and have a pole structure (good-bad, correct-incorrect, potential difference exists -potential difference does not exist). There are several ways to determine the constructs. In general, the researcher and the interviewee decide them together. However, the researcher alone can determine the constructs as well, which may result in the inflexibility of the grid. RGT retains the flavor of qualitative methodology while at the same time providing the opportunity for quantitative analysis. (Aztekin,Arikan and Sriraman, 2010)

THE RESEARCH INSTRUMENT

In particular, the concepts of short circuit, potential difference and current were underlined and 10 elements were selected. The elements are presented in Table 1. These elements were then translated into physical grids by the researcher in a way that the students could comprehend. The researcher determined the relevant constructs for the selected elements. The constructs are presented in Table 2.

Table1. Elements

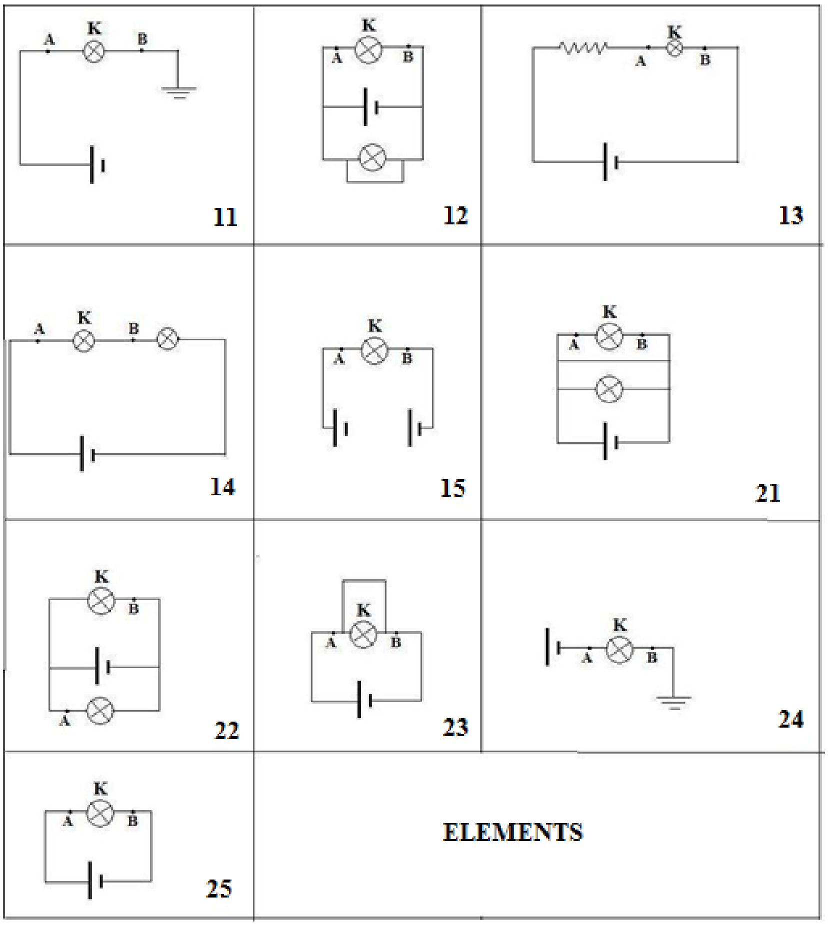

Table2. Constructs

1	11	12	13	14	15	21	22	23	24	25	5
Current flows through the circuit											Current does not flow through the circuit
Energy of the battery increases											Energy of the battery decreases
Current divides into branches											Current does not divide into branches
Current flows through point A											Current does not flow through point A
There is a potential difference between point A and B											There is no potential difference between point A and B
Bulb K lights											Bulb K does not light
Potential in point A is greater than point B											Potential in point A is smaller than point B
There is a potential difference between the poles of the battery											There is no potential difference between the poles of the battery
Current value through point A is greater than point B											Current value through point A is smaller than point B

The reason why the researcher chose the constructs is in order to focus on the concepts of circuit, potential difference and current.

PROCEDURE

The 10-element grid, prepared by the researcher was presented to the candidate teacher of physics, who was then asked to rate all the elements according to the constructs. All the elements were rated on a 5-point scale by the participant. For a pole of the construct, 1 stands for 'reflects fully'; 2 for 'to a great extent'; 3 for 'element is in the middle according to this construct, or indecisive'; 4 for 'reflects poorly'; 5 for 'not at all - contrast'. In this manner, each element was rated as terms of the obtained constructs until each construct was applied to the elements. The result of this procedure was a matrix that displays a construct in each row and has a 5-column section evaluated by a 5-point scale. An element, evaluated with 1 means that the construct strongly applies to this element, while 5 indicates that there is a strong, contrasting construct.

The participants' grid was qualitatively analyzed by the computer program GRIDSUITE.

FINDINGS

The grid compiled by the candidate teacher of physics is presented in Table 3. The data obtained from this grid are analyzed. The comments of the candidate teacher of physics about the elements are as follows:

- In Element 11, current occurs from the positive pole of the battery to earth. Thus, there is a potential difference between point A and B. Point A is at high potential. Current decreases at the resistor.
- In Element 12, electrical current splits into branches, whereas the current in the similar circuit in Element 21 does not split.

- In Element 13, potential difference and current are related, and direct current is produced. Potential of point A is greater than that of point B. Current decreases at the bulb.
- In Element 15, direct current occurs from high potential to low potential.
- In Element 21, the bulb does not light because of short circuit.
- In Element 22, current splits into branches. Potential of point A is greater than that of point B. Current decreases at the bulb.
- In Element 23, current flows, the bulb is not subject to short circuit. Potential of point A is greater than that of point B. The current that flows through point A is greater than the current that passes through point B.
- In Element 24, electrical current occurs from earth to the negative pole of the battery. The current that passes from point B is greater.
- In Element 25, potential of point A is greater than that of point B. Current decreases at the bulb.

The candidate teacher of physics made the same evaluation for Element 14 and 13, considering also that the bulb is a resistor. The participant stated that the current splits into branches in Element 12 and 21, however, she/he did not realize the short circuit in Element 21. Furthermore, the participant made an incorrect rating in element 15 because she/he thought that direct current would occur from high potential to low potential before the circuit is completed. The participant stated correctly the relationship between potential difference and current in Elements 13, 12 and 25. According to Elements 25, 22, 13 and 11, the participant thought that the current decreases at the bulb.

Table 3. Participants' Grid

1	11	12	13	14	15	21	22	23	24	25	5
Current flows through the circuit	1	1	1	1	1	1	1	1	1	1	Current does not flow through the circuit
Energy of the battery increases	5	5	5	5	5	5	5	5	5	5	Energy of the battery decreases
Current divides into branches	5	1	5	5	1	5	1	5	5	5	Current does not divide into branches
Current flows through point A	1	1	1	1	1	5	1	1	1	1	Current does not flow through point A
There is a potential difference between point A and B	1	1	1	1	1	5	1	1	1	1	There is no potential difference between point A and B
Bulb K lights	1	1	1	1	1	5	1	5	1	1	Bulb K does not light
Potential in point A is greater than point B	1	1	1	1	1	3	1	1	5	1	Potential in point A is smaller than point B
There is a potential difference between the poles of the battery	1	1	1	1	1	1	1	1	1	1	There is no potential difference between the poles of the battery
Current value through point A is greater than point B	1	1	1	1	1	3	1	1	5	1	Current value through point A is smaller than point B

By means of GridSuite4, the similarities between the elements and conducts were examined and presented in Table 4. The significant differences were evaluated by the researcher. The participant rated Elements 11, 13, 14 and 25, and Elements 12, 15 and 22 100% similarly. The participant made the 100% same evaluation for the conducts "Current passes through the circuit" and "Energy of the battery decreases", and likewise between the conducts "Current passes through point A" and "There is a potential difference between point A and B".

As a result, the students are aware of the fact that potential difference causes current. This is evident from the 100% match between the constructs “Current passes/does not pass from point A” and “There is (no) potential difference between point A and B”. Equally, the constructs “The energy of the battery increases/does not increase” and “Current passes/does not pass through the circuit” are 100% similar. This demonstrates that the students correctly construct the relationship of the energy of the battery with current. When the similarities among the elements are observed, it is seen that element 13 and element 25 are 100% similar. Hence, the students think that when the current passes through the bulb, it will light. Moreover, it is observed that the students have a misconception stating that the current will decrease once it passes through the resistor.

The participant rated correctly Elements 21 and 23 among the elements 12, 21and 23 about short circuit, which indicates that the participant is familiar with the concept of short circuit and is capable of interpreting. However, the participant could not notice the short circuit in Element 12. Moreover, the participant believed mistakenly that current would occur in the circuits 11, 15 and 21. This is because the participant knew that direct current would occur from high potential to low potential and felt into error that potential difference would occur.

RESULTS AND DISCUSSIONS

This study sought to reveal the usability of the RGT in DC electrical circuits and the concept image of the participant, concerning the subject. It was found out that detailed information about short circuit, potential difference and current could be obtained by investigating the prepared grid. It was seen that the students did not use numbers other than 1-3-5 in the grid rated from 1 to 5. This could be interpreted as an indicator of the certainty of the students about their ideas on the concepts. A misconception, which states that the current would decrease once it passed the resistor, was found out among the participants. The studies by Pardhon and Bano (2001), Küçüközer (2003), and Çıldır and Şen (2006) also state a similar misconception among students. It was observed that the Repertory Grid Technique is practical to reveal the misconceptions.

It was observed that the participant knew that direct electrical current would occur from high potential to low potential, nevertheless, she/he did not know how potential difference is produced in batteries. Although the participant is theoretically knowledgeable about the issue, his/her practical comments were incorrect.

Students' acquisition of knowledge is a common objective of science teachers. As emphasized by Fetherstonhaugh (1994), and Winer and Abend (1995), the RGT may provide science teachers with a valuable source of information. In science education, the RGT has been widely recommended and used in a variety of ways to observe the change in students' understanding of concepts over time, and to assess the knowledge of the learner. We suggest that the Repertory Grid Technique be used in assessing declarative and procedural knowledge in science education.

ABSTRACT

Research that claims to be participative and that aims for redress needs to be inclusive from the framing of paradigms through to the research products. When carrying out research in rural contexts, conceptualising research questions, decisions on data collection methods, the choice of instruments, data analysis, and ethics, the ownership and dissemination of findings, have to be made in a way that fits with the worldview and life context of participants. In South Africa, research grounded in Ubuntu can be one way of ensuring consonance with the participants' worldview. In this framework, research quality is largely dependent on the researcher's willingness to establish authentic relationships with participants, and to recognise community structures, knowledge and values. Ubuntu, as an African philosophy, is relevant and meaningful to rural South African participants (Venter, 2004), and is therefore likely to result in meaningful science education research. We have learnt that we may not enter a community from a perspective of 'superiority', or even 'objectivity', but need to indicate our willingness to co-learn with participants throughout the research process. In this paper we discuss how ubuntu can support and underpin rural research – as well as extend the boundaries of conventional research design. We consider the implications of using ubuntu as a guiding principle in research in rural communities, drawing on experiences from the early part of our engagement with the participating community. This paper's contribution lies in opening dialogue on approaches to science education research in rural contexts.

Keywords: *ubuntu; rural education; participative research*

INTRODUCTION

This doctoral research into Indigenous Knowledge (IK), ubuntu and the science curriculum seeks to discover science-related community knowledge and practices which could be used in classroom learning. This aim aligns with the principles of the South African National Curriculum Statement, which requires the inclusion of IK into school subjects. We work with high school students in a rural community in KwaZulu-Natal, South Africa. Elders in the community pass on IK to the youth. It is this resource of wisdom and knowledge, particularly relating to natural phenomena and ways of living in nature, that we explore with the community. As outsiders we can serve a bridging and facilitating function that will possibly allow the recognition and inclusion of this knowledge into the classroom. We draw on the principles of ubuntu throughout the research to make decisions on ethics, time frames, data collection, data analysis, as well as dissemination of findings. Our research uses a participatory approach, concurring with (Bernstein, 1983), that research paradigms reflect our beliefs about the world. This paper reports on the methodological implications of using ubuntu as a framework and describes instances to support a model of participatory-ubuntu research in a rural setting in South Africa.

WHAT IS UBUNTU?

There is no single definition of ubuntu and it is difficult to define the concept accurately (Mnyaka & Motlhabi, 2005). Bishop Desmond Tutu, the Chairperson of South Africa's Truth and Reconciliation Commission (TRC) had this to say about ubuntu:

> Ubuntu is very difficult to render into a Western language. It speaks of the very essence of being human…It is to say "My humanity is caught up, is inextricably bound up in yours". We belong in a bundle of life (Swanson, 2007:58).

The term ubuntu is as old as many African languages, but has only more recently entered academic discourse. Ubuntu is the Zulu version of 'botho' (Sotho/Tswana), 'unhu' (Shona), 'bunhu' (Kalanga and Tsonga), 'umuthu' (Malawi), 'umundu' (Yawo), and 'vhutu' (Venda). It means: 'being human' or 'humanness' (Mdluli, 1987). It is a philosophy that not only promotes the common good of society (Venter, 2004) but is also a way of conceiving reality. There is controversy on whether ubuntu is uniquely African, or can be found in other parts of the world. Kamwangamalu (1999) makes reference to historical events such as slavery, colonialism, apartheid, and Nazism to dispute the existence of ubuntu virtues is Western societies. Gaylard (2004) and Louw (2004) however report the existence of ubuntu-related values in both Western and Eurasian philosophies respectively. It is our opinion that ubuntu is a feature of traditional societies, which has persistently faced erosion from modernisation (which often carries with it secularization, rapid urbanisation, individualism and materialism). As Venter (2004:149) puts it, "ubuntu is an ideal concept, often flawed in interpretation and practice". Like other indigenous values, ubuntu is under threat, hence the call in both academic and political circles for its revival.

The principles of ubuntu are part of the fabric of rural communities (notwithstanding the fraying of the fabric at times) and are recognized as contributing to community wisdom and survival. These principles include: respect, communalism, interdependence, supportiveness, solidarity, cooperation, caring for others, and participation for the common good (Hamminga, 2005; Keane, 2007; Malcolm & Alant, 2004; Olinger, Britz, & Olivier, 2007; Tambulasi & Kayuni, 2005; Venter, 2004). Ubuntu is the basis of the African worldview. Ubuntu affirms the humanity of the individual in direct relation with fellow humans, and it carries positive connotations of fostering and manifesting qualities of kindness and neighbourly support (Louw, 2004). The South African Welfare Department defines ubuntu as a principle for caring for each other's well-being, where each individual's humanity is expressed through his/her relationship with others (Department of Welfare, 1997 in Tambulasi and Kayuni, 2005). A person can therefore be commended as '*having* ubuntu' or negatively described as '*without* ubuntu'.

Ubuntu is valued in indigenous communities, where relationships are at the centre of worldview. It is clearly expressed in the Zulu/Xhosa maxim, *umuntu ngumuntu ngabantu* (i.e. a person is a person through other persons). Expressed thus, ubuntu can be interpreted as a rule of conduct or social ethic (Louw, 2004). Ubuntu is often described as the foundation of all African societies (Mdluli, 1987) and as the basis of African communal life (Tambulasi and Kayuni, 2005). It contributes to the sustenance and well-being of a people (Venter, 2004).

For the purposes of our research in general and this paper in particular, we use two definitions from Kamwangamalu (1999).

> …ubuntu is understood as a collective solidarity whereby self is perceived primarily in relation to the perception of others, that is, persons are perceived less as independent of one another, and more as interdependent of one another (Laden, 1997 in Kamwangamalu (1999:26).
>
> Ubuntu is about how you relate to people and is …a fountain from which actions and attitudes flow (Dandala, 1996 in Kamwangamalu, 1999:26-27).

Ubuntu is not just about human acts, but about being. It is a disposition and an orientation that seeks to contribute towards the well-being of others (Mnyaka & Motlhabi (2005). Through ubuntu, the individual becomes conscious of his/her being, privileges, and responsibilities towards self and others, and is able to say, "I am, because we are; and since we are, therefore I am" (Mbiti, 1969).

UBUNTU AND RESEARCH

The use of ubuntu in research is a relatively recent phenomenon but is gaining ground in educational studies in South Africa. Its use comes from the growing need for research oriented towards social justice, research that gives space to the democratic, egalitarian and ethical engagement of participants (Swanson, 2007). In the rural South African context, the framework of ubuntu is consonant with the worldview of research participants (Malcolm & Alant, 2004). Ubuntu aligns with paradigms that acknowledge rural research participants' perspectives and interpretations, even though not necessarily satisfying universal 'truths' (Muwanga-Zake, 2009). Swanson (2007) used ubuntu as a guiding principle for fieldwork based in qualitative research methodology. Keane (2005) used ubuntu to explore a South African rural community's understanding of relevant science and Muwanga-Zake (2009) used ubuntu as a philosophy and methodology in evaluating a computer educational programme. Because people are not born with ubuntu, but acquire the communally acceptable and desirable ethical standards throughout life, it would be of valuable for education and education research to make use of this framework (Venter, 2004). Our decision to use ubuntu as a guiding principle results from an understanding that it would not be appropriate to research into Indigenous Knowledge using methodologies that do not give room for interaction at a more personal level.

The use of ubuntu especially in a participative approach leads to sensitivity to participants' perspectives and affords multiple insights (Swanson, 2007). It gives room for respectful relationships and cross-cultural understanding between the research partners. Through its emphasis on responsibilities and obligations towards collective well-being, the use of ubuntu helps to break the 'I-You' dichotomy of traditional research (Swanson, 2007). It gives research a human face as it respects participants' values, norms and needs and emphasizes collaboration. The use of ubuntu has the potential to improve the validity, relevance and usefulness of the research outcomes by bringing the partners closer in purpose. Ubuntu is thus an empowering process (Muwanga-Zake, 2009). Venter (2004) recommends that education in Africa needs to pay attention to interpersonal and cooperative skills, and we suggest the same for research. In using ubuntu we note Minkler's (2004:687) advice that "…the quality of findings…is directly and immeasurably affected by the actions when beginning and maintaining a working relationship professionals and citizens".

IMPLICATIONS OF USING UBUNTU: OUR EXPERIENCE

One clear requirement of this approach is flexibility and lengthy engagement. We recount here a story of the initial stages of the research. From the beginning, the implications and consequences of being grounded in a framework of ubuntu are far-reaching and at times challenging. Our partnership is now six months long, and we have used the time to foster relationships and to co-design the research with the community. The community participating team comprises thirty 11th Grade Physical Sciences and Life Sciences students, a community youth leader who is also a research assistant, two teachers and six community elders.

In our first visit to the site we had planned to discuss with the school and local authorities, the participating non-government organization, the elders and the students our idea to explore indigenous knowledge within the community. We hoped to comply with University ethics requirements by immediately issuing information sheets, consent forms, as well as questionnaires through which we wanted to collect data on students' prior knowledge, (all carefully translated into isiZulu). We held a meeting with representatives of local and provincial government departments. The robust discussion we had with them gave us the opportunity for self-reflection. Questions on issues such as how the community would benefit and how they would feel a sense of ownership of the project were raised. How would we provide for sustainability? What would we do about the raised expectations? Could we guarantee prolonged engagement? We realized that the production of knowledge for its own sake is not a priority for a community faced with pressing needs of employment, food security and health. We realized we had to balance academic requirements with a consideration of community needs so that the process as well as product of the research is immediately beneficial to both sides. It also needed to leave a knowledge legacy and not simply to terminate with a thesis outcome. Discussions with representatives of the traditional council also showed we are not supposed to impose our timeframes on the participants, but respect their commitments outside our engagement with them. This experience showed us that our plan, though in principle committed to ubuntu, needed to be flexible and provide for extensive changes based on the field experience of interacting with participants for it to be really grounded in ubuntu.

After this practical learning on our part, we understood that we should only give verbal explanations of our university ethics requirements at this stage, and left the potential participants to think about and further discuss the project. We realized that the signing of forms could only happen at a later visit. We had no right to propose contractual relationships. Rather, we formed relationships with a group of youth who wished to be involved. The youth leader was to be our main community research assistant on the understanding that fixed remuneration was not possible but that as funding may allow we could contribute a stipend on an ad hoc basis. In participative research the balances between power, partnerships and purposes are complex. Through an understanding of ubuntu it became easier to establish a collective intention that 'we are in this together'. We now had a community intention rather than a researcher-participant contract.

We are also aware of the importance of language in this context. We are not first language Zulu speakers but we have and will continue to try as far as possible to communicate in isiZulu. In situations where we think we may not be able to accurately communicate in the local language, we will seek help from our research assistant. In our communication with the students, we also are aware of their difficulties with English, so we encourage them to speak in isiZulu if this makes them feel more comfortable. We are also aware that there might be some among the elderly participants who may not be able to read and write, so we requested our research assistant to assist where necessary. As far as possible we liaise with the research assistant, the participating teacher and the Secretary of the Traditional Council, on the relationship hierarchies and dynamics of the community so that we may also try to fit in. We continue to seek ways of developing a deeper understanding of the participating community and to also create opportunities for them to participate in our contexts. We arranged a lunch outing with key leaders in the broad community where the research agenda was not the focus. We also co-hosted the community researcher in Johannesburg. These are examples of going beyond the research plan to creating an authentic expression of ubuntu in practice.

Using ubuntu sometimes implies listening to issues that may not be directly related to the research. The participants listen to our needs and our agenda, and in a situation of mutual respect and understanding, we also listen to their concerns. This involves continuous decision making on ethics issues throughout the research process. We get privileged access to inside information, which our ubuntu principles do not allow us to disclose. We view having a participant share that kind of information with 'outsiders' as evidence of the growing trust with the individual and the community they represent. Such conversations are also an opportunity for continuous feedback on both individual and community needs. As a result we look to the engagement with the community with optimism.

Using ubuntu requires a commitment on the part of the researcher to keep promises, so that participants also see their commitment as binding. Our student participants requested that we should play the video recordings on our discussions on their prior knowledge. In our next visit we will play them the video clip. This is part of information sharing. Being able to watch and listen to their own voices is an important contribution to empowerment for most of these students. Playing the videos may even encourage some of the students to contribute in coming discussions, and may also be used as member checking on opinions previously expressed. It is possible that playing of the video clip to students may form a basis for new discussions. In a similar way we make sure that any photographs are duplicated for community members.

In our engagement with the community we are conscious of the need to ensure participants are meaningfully engaged. Consequently, we managed to have one of the participant teachers attend a conference on research in science and mathematics education, which she described as a great learning opportunity for her. Whenever we have opportunity we are keen to have the community directly benefit. We plan to share the research findings with participants in the form of a community exhibition centre for the knowledge found in the research. A summary of the findings authored by all participants will also be presented in a booklet in both English and isiZulu. These sometimes uncalculated turns and unfoldings of lived engagement present challenges for a PhD student within the academy and also for funders who expect a more rigid and template-constrained plan.

In a prolonged engagement such as in our research, we keep in mind the need to continue in conversation with the community, making decisions together with them on data collection, data interpretation as well as decisions on how to use the data for the benefit of the community. We view the research as a continuous learning process for all partners.

CONCLUSION

Our experience in the field so far has shown that the use of ubuntu presents both benefits and challenges. We have learnt the importance of continuous dialogue and the need to develop trust amongst all research partners. We all believe the research process has potential to contribute to local level decisions on curriculum design and development in a way that recognises local knowledge and potential. By aligning the research process to the aspired outcomes, participative engagement both contributes to more authentic knowledge and to the benefit of all participants.

ACKNOWLEDGEMENTS

We wish to acknowledge the contributions of the all partners in this research project. Special mention goes to Skhumbuzo Mlibeni (youth leader and research assistant); Anastasia Ndlovu (Physical Sciences teacher) and Beauty Majozi (Secretary of the Traditional Council).

CURRICULAR ISSUE OF FORMATIVE ASSESSMENT IN SLOVENE PRIMARY SCHOOLS

Natalija Komljanc

The National Educational Institute

1000 Ljubljana, Poljanska 28, Slovenia

natalija.komljanc@zrss.si

ABSTRACT

This text presents the secondary analysis of the applicative results development of the Institute's project in the years from 2006 to 2009, in which 34 Slovene primary schools participated actively. The new didactic approaches demand teacher's flexibility according to the class subject they teach. Formative accompaniment in the evaluation process, which includes the teacher's feedback about the value of student's knowledge, is one of the basic didactical approaches for introducing the transformative pedagogy to Slovene schools. This approach derives from constructivist principle emphasizing classes that are student oriented in order to encourage student's learning style. By using the formative assessment, the teacher encourages students to produce autonomous, critical, and creative thinking and to act independently when choosing ones own learning style and interesting learning contents. Moreover, it encourages him/her to look for the solutions to the problems that may occur at any class subject. Along with the paradigmatic school transformation from mechanical or transmission schools into holistic or transformational, the formative assessment differs in main elements from the traditional assessment. The formative assessment does not permit the students to be fully engaged without the parent's or teacher's help in realizing their individual curriculum, which is accordant with the compulsory national curriculum. This text will show how the individual and social cooperation level can intertwine between the educational participants.

Keywords*: formative assessment, curriculum, teachers' training, knowledge, transformative learning.*

INTRODUCTION

Formative assessment is becoming one of the moving forces of the learning process. In this way, Vygotsky’s theory of proximal development and cooperative learning between teacher, student and schoolmates is confirmed (Vygotsky, 1977 in Komljanc, 2004).

Formative assessment is becoming a focus in the professional development of teachers, and also a focus in policy documents on educational assessment (Bell, Cowie, 2001).

In the national project development, it was affirmed that the effective feedback is the key element of pedagogic communication within the learning process and/or self-development. The qualitative measuring of learning can essentially contribute to a better learning motivation, to longer schooling and consequently to higher professional education of our citizens (Komljanc, 2010). These theses enable to look more carefully on the benefits of formative assessment for learning and on science.

This article includes some descriptions of facilitating formative assessment from "bottom up" approach. There are also some characteristics of formative assessment, some definitions and references for more efficient formative assessment in science education.

SOME CHARACTERISTICS OF FORMATIVE ASSESSMENT

Formative assessments have evolved as a means to adapt to students' needs. As opposed to a summative assessments designed to make judgments about students' performance and produce grades, the role of the formative assessment is to improve learning. Benchmark tests are used to predict students' performance on other tests (most often state assessments) whereas the formative assessment tests are intimately connected to instructions.

Since, in this phase, a teacher redirects from the content or discipline focused education to the consideration of students' needs, it signifies that the teacher should be capable to deal with the procedures. Moreover, at the same time (s)he should play a role of an emphatic wise man, who helps students not only to perceive, comprehend but also to test, examine, strengthen and interpret solutions or procedure and to provide sensible procedure positioning in the system.

The formative assessment theory derives from the critic of weaknesses of the existing education and assessment, which were behaviourist oriented, program centred, curricular focused, mechanic and uniformed and whose goal was repetitive knowledge (Komljanc, 2008). At the same time, the formative assessment corresponds to the modern education needs for achieving mutual communication, cooperation between partners, process oriented knowledge and transformative learning.

Formative assessment has a long history. Historically, formative assessments were of instructional units and diagnostic assessments were used for the placement purposes. Formative assessments are a part of instruction designed to provide crucial feedback for teachers and students. Assessment results inform the teacher about what has been taught well and what not so well. They inform students about what they have learned well and what they have not learned so well.

Feedback in formative assessment most drastically interferes in learning instructions. The latter are not only the described steps for single-meaning and unconditional imitation of the function (operation) that has already been excellently performed several times but person-oriented recommendations including not only regulations but also principles for qualitative pro-active existence and successful solving of conceptual plans or well-received innovations and sensible innovation procedures.

The group research has shown that the formative assessment, which is student oriented, raises the knowledge level and generally improves the quality of education because it minds what a student has to say, which influences on the learning process. Therefore, teachers are advised to replace the simple passing of subject contents and "closed" teaching style, which limits communication possibilities, by interactive style, for which they take enough time so they can think about students' reactions and leave students enough time to display these reactions. The most common mistake teachers make, is that they do not give enough time to students to provide answers and instead teachers answer by themselves as they are more interested in the value of content transmission and not in students' comprehension. Teachers' interest in a child leads him/her toward listening student's reflections on the content and determining his/her comprehension. Feedback in that sense is more frequently content oriented and rarely methodologically oriented (Komljanc, 2004).

"Competing, who will be the first to raise the hand and shoot the correct answer, is meaningless. Even the incorrect answer or "*I don't know*" answer can be a good starting point for student's and teacher's reflections. In the contemporary, dynamic world, frequently not only one correct answer is possible" (Black, 2009). According to Black, the right learning method upgrades ideas that students already have. That is why teachers should give up the role of a fact presenter and explainer and adapt the role of a research promoter. At Kong's College in London, the research on the impacts of classic assessment showed that it stimulates only superficial knowledge and does not consider students' needs because there is too much emphasis on the quantity and not as much on the content and quality of knowledge. "Children compete instead of focus on learning" (Black, 2009). Formative assessment, which is constructivist and not behaviourist oriented, encourages learners to learn and teachers to focus on a student and not only directly on the subject discipline.

Teachers should be interested in students' thinking abilities that are why they have to put more effort in forming "right" questions instead of searching for the "right" answers. Likewise, they should be aware of the fact that there is no evidence proving that a frequent examination raises the knowledge level. On the contrary, examinations often unnecessarily burden teachers and students. According to Black and Wiliam (1998), using only summative assessment has the negative impacts on learning. Which arguments do they use? We are dealing with school-based formative assessment. Everybody should be allowed to show their best qualities and respect their good deeds. We are becoming mature by considering also other viewpoints. Even the incorrect answer or the "I don't know" answer may be a good starting point for creative thinking. Teachers should take time to reflect on students' reactions.

In the past, schools were mainly interested in transmitting knowledge from generation to generation as faithfully as possible. The school of the 21st century is no longer oriented toward imitating but it encourages all education factors to discover (invention) and to update usefully and concretely (innovating). The classic knowledge assessment is not sufficient even for the so-called corrective purpose, not to mention achieving the goal of encouraging creative thinking and concrete realization of ideas and presenting as well as interpreting findings. Constructivist formative assessment takes into consideration all basic learning forms, which is the most humane and cognitive beside the social constructivism. Creators avoid behaviourist methods, which they use mainly for assuring accuracy when defining the basic notions for comparing and constructing new compositions.

Some definitions of formative assessment

Over the last decade and even more, there has been a major interest in a number of countries on the assessment for learning or formative assessment. One of the driving forces for this has been work of Black and Wiliam (1998) from the Assessment Reform Group in London.

Hargreaves (2005) argues that there are various conceptions of assessment for learning such as: monitoring students' performance against targets or objectives, using assessment to inform next steps in teaching and learning, giving feedback for improving students' knowledge, some kind of control or turning assessment into a learning event.

Bell and Cowie (2001, p. 552) put out in their article titled The Characteristics of Formative Assessment in Science Education nine characteristics of formative assessment that were identified by the teachers. The characteristics are:

1. responsiveness;

2. sources of evidences,

3. tactic process,

4. usage of professional knowledge and experiences,

5. an integral part of teaching and learning;

6. formative assessment is performed by both teachers and students;

7. purpose for formative assessment;

8. contextualized nature of the process; and

9. dilemmas.

Slovene teachers have the same response when they were asked about formative assessment in the process of action research. The teachers and students as well as their parents and school leaders supported the formative assessment even more after the development-applicative project.

Formative assessment is described in the policy document as: … "the integral part of teaching and learning process". It is used to provide the student with feedback, to enhance learning and to help the teacher understand student's learning. It helps to build an image of a student's progress, and informs about the next steps in teaching and learning (Ministry of Education, 1994, p.8 in Bell, Cowie, 2001, p. 538).

Along with the formative assessment development, the project group in Slovenia came up with three definitions of formative assessment regarding the development of participants' abilities to implement changes in the school-based evaluation (Komljanc, 2009):

1. Formative assessment is a form of prior knowledge development on higher levels (Komljanc, 2007);

2. Formative assessment is a form of mental development – ability to comprehend, judge and behave (Komljanc, 2008);

3. Formative assessment is a feedback for better knowledge (Komljanc, 2009).

In the initial phase of innovative evaluation, performers dedicated their attention mostly to diagnostics and forms of pedagogic communication for attaining higher knowledge levels. The cognitions on the motivation quality have impact on the development of definition in the sense of developing the teaching quality in order to offer the possibilities to comprehend and not only to receive information regarding the prior knowledge. All together gradually brought teachers to the conditions required for the implementation of process oriented education. To achieve this, most teachers spent at least three years intensively working on their methods, actively following counselling on how to develop one's own practice, pedagogic communication, how to cooperate and motivate students, who are an essential element in learning process.

The new communicative didactic approaches demand teacher's flexibility in the teaching process, especially in diagnosing the student's prior knowledge, creating education strategies and evaluating achievements. Formative assessment of the learning and teaching development, which includes the teacher's feedback on student's knowledge value and student's information on teaching value, is one of the basic didactic principles for the implementation of transformative pedagogy in Slovenia. The formative assessment originates from the constructivist principle of the student oriented learning process for the development of learning style of an individual student within a social learning group. By introducing formative assessment, a teacher accustoms each student to an autonomous, critical and creative thinking, as well as to the self-initiative choice of student's own learning style and interesting contents. Moreover, it encourages a student to find solutions to the problems at every school subject.

The constructivist formative assessment stimulates cooperation and efficient dialogue between learners. With the adult's help (parents, teachers and other experts), children develop self-regulative pattern when choosing their learning style. Thus, the self-regulation is the base for implementing transformation. At the formative evaluation, student cannot be entirely engaged without the parents' and teachers' help in crating individual curriculum, which is consistent with the compulsory national curriculum. The school is actually optimal only when it enables student's personal development which, in a certain development phase and environment, (s)he could not attain without the help of adults. This is in fact the point of schooling.

Progress is the main aim of the definitions of assessment knowledge in Slovenia and in New Zealand. This aim can be suitable also for science teachers and students. The definition of the formative assessment recognizes the benefits in the process of students' learning and teachers' support (Cowie, Bell, 1996 in Bell Cowie, 2001).

Some other definitions of formative assessment underline some important didactical component such as:

1. formative assessment is a dynamic process,
2. formative assessment is a form to help students in his or her learning process,
3. formative assessment is a continuative services of instructions,
4. formative assessment is a form of accompaniment,
5. formative assessment is improving the didactical dialogue between learners and teachers and also parents,
6. formative assessment is a form of arranging learning data for future planning of learning and teaching,
7. formative assessment is an approach for selecting learning aims,
8. formative assessment is a strategy for regulating education process,
9. formative assessment is an archive of achievements…(Komljanc, 2004).

Some benefits of formative assessment for assessing science knowledge

In New Zealand and also in Slovenia, we have had different didactic approaches for better measurement in education, but all of them were very much oriented on continuous summative assessment. The most popular feedback has been grades and external examinations.

The response to these criticisms can be summarized as a need to assess a wider range of science learning outcome, such as performance of investigation skills (Johnson, 1989 in Bell, Cowie, 2001, p. 537) and multiple forms of thinking (Gardner, 1985 in Bell, Cowie, 2001, p. 537). There are also proposals for using wider range of assessment tasks or instruments and performance-based assessment. Assessment knowledge must be integrated with the curriculum and assessed in a more open, humanistic and constructivist way.

Slovenian teachers who were supported by advisers in project of the National Education Institute were using a guiding instrument with the focus on the diagnoses of the prior knowledge, awareness of teaching aims and learning outcomes and also on process of learning and teaching and consequently on students' learning style. In the process, the instrument enables teachers to reach the optimal achievements of each student in the learning group.

Not just in Slovene and in New Zealand but also in other countries like UK, Australia, Singapore, Hong Kong teachers are aware of the difference between formative and summative assessment knowledge (Komljanc, 2009).

Students can benefit from formative assessment in the following ways:

1. developing divergent thinking,
2. using reflection as a sort of analysis,
3. opportunities for searching different methods of observing and interpreting data,
4. planning the process of learning and teaching at the same time,
5. constructing various research questions,
6. orientation on process for developing prior knowledge,
7. integrating different content more often,
8. using different sources,
9. developing not just actual but also reference knowledge,
10. more autonomous study with orientation on self-regulation,
11. discovery approach, with defining the hypotheses,
12. experiences and theoretical knowledge use.

When teachers start with formative assessment, they ask for help by asking question like "How to start reforming the assessment system?" In Slovenia, The National Education Institute helps them by offering three principles instead of classical roles and five recommendations for reconstructing an innovative school measurement system. They accept also two indicators, which are briefly presented further on:

Three principles of knowledge assessment, which were very well accepted, are (Komljanc, 2008):

1. "Assessing strong and weak knowledge."

This principle was not so often used at the beginning. Only 3% of the project members use diagnostic approach, but after working in project team during three years, 98% teachers accept prior knowledge in planning the system.

2. “Assuring contact between learning levels”.
   Nobody was oriented on personal learning. Almost all used the classical teaching style. After a three-year usage of the instrument for formative assessment, 76% of teachers replaced the old teaching style with a more personalized teaching approach.

3. “Assuring actual feedback on the knowledge development.”
   At the starting point, 17% of teachers knew how important useful feedback was, but at the end of the project, 96% of teachers confirmed, that they are very much oriented on the effective positive feedback in the learning process, which means that the teacher and the student have improved their learning and teaching.

All three principles can be also useful for students and teachers in science matter.

Teachers found help in the suggestions or recommendation for realizing principles. Such as (Komljanc, 2010):

1. Exchanging information between the education factors for balancing needs and abilities and curriculum requirements
2. Counselling on how to eliminate weaknesses in prior knowledge – learning on higher level
3. Directing learning process for (co) influencing of factors
4. Control mechanism in the form of feedback for balanced learning and teaching
5. Summative assessment on the basis of complete information collection on student’s prior knowledge and improvement which is compared with reference measurement (the expected outcome)

For teachers, especially the first and the fourth recommendations are beneficial, as well as the last one. The biggest improvement was achieved with the first principle (7% at the beginning, 68% in the middle of the project, and 95% in the end). We can recognize that the Slovenian teachers improved formative assessment knowledge with better dialogue between teachers and students. Now, a more beneficial feedback is used in the learning process (7% at the beginning, 68% in the middle of the project, and 95% in the end). Therefore, we could conclude that the summative assessment is also more valid and reliable (14% at the beginning, 25% in the middle, and 78% in the end). Reliability in a sense of repeating the same response and validity in the sense of how good or correct the comparison between actual and reference level of knowledge was. There are still some possibilities for improving teaching methods and style. Teachers should more often give the needed personal instructions (29% at the beginning of the project, 78% in the middle, and 73% in the end). They should be also more oriented on the so-called sensible learning and on learning measurements or reference level of knowledge (14% at the beginning of the project, 25% at the middle, and 78% in the end).

In order for the teachers to perceive successful reactions in the upgrading of evaluation system, we have created two indicators. The first one pointed out the successful implementation of a lesson and the second signalized that the student has a greater knowledge than before (Komljanc, 2008). Both indicators directed the teacher and the student toward the qualitative inner control of learning and outcomes.

These indicators are very similar to the third trend of formative assessment, which is to match the views of learning, recognizing that each learner has to construct an understanding for her - or himself, using both incoming stimuli and existing knowledge, and not merely absorbing transmitted knowledge (Berlak, 1992; Gipps, 1994 in Bell, Cowie, 2001, p. 538). Central part of this teaching is the dialogue with students to clarify their existing ideas and to help them construct the scientifically accepted ideas which is very important for science teaching (Scott, 1999 in Bell, Cowie, 2001, p. 538). Formative assessment is a crucial component in teaching science and also others subjects with which agrees also Bell (Bell, 1995 in Bell and Cowie, 2001). The essential part of formative assessment is feedback or a dialogue because it can modify a learning effectiveness. It is also important that the feedback provide a generalization of the data, which can be also very useful in science teaching. In that way, students have the opportunities for rethinking and because of that they may have a dipper understanding of the scientific learning problem. Learning, teaching and assessment interconnected with feedback. The process of teaching is never done without the student's involvement. Their reflections are part of research work and also a part of the interpretation of their recognitions. As Gitomer &Duschl, 1995, p. 307 in Bell Cowie, 2001 said, the assessment is a continuous process that facilitates instructional decision making in the classroom.

CONCLUSION

The compilation between Slovene and New Zealand experiences in classrooms shows that the formative assessment is increasingly becoming a focus in the professional development of teachers and also headmasters. It is more supported by policy documents on educational assessment. The National Educational Institute has a web site with recommendations. There are three booklets in the last three years. The seminars are also supported by government and they are very well accepted by teachers. The National Education Institute has established a net for compulsory schools with continuous support for the teachers, engaged in the project, in developing formative assessment knowledge in practice.

The most beneficial is the purpose to change from standard to multiple purposes and because of that teacher with students develops different measures. Different measures can help also in raising standards in science field.

If we have an opportunity to compare and at the same time to improve standards with expected outcomes then we have also an opportunity to develop standards of knowledge in some culture areas. At the same time, we can also improve personal learning aims of each student. In this way, we actualize the actual and reference level of knowledge.

From policy point of view, the constructivist formative assessment "improving learning, reporting progress, providing summative information and improving programs" was recognised also in New Zealand (Bell, Cowie, 2001, p. 538).

Both, formative and summative assessment influenced on learning, but in different ways. While the formative assessment improves learning by fulfilling the learning gaps and correct misunderstanding, the summative assessment gives an external force for improving student's knowledge, but more or less without accurate instructions. From the research perspective, the formative assessment is more valuable for developing knowledge based on research questions. Because of the past experiences in summative assessment, we should do more research on formative assessment knowledge to recognise the benefits.

Our evaluation system does not follow the example of formative system in other countries as much as it should. Other countries actually achieve good results at the international knowledge measurements. Besides, contemporary tendency is suggesting more profound work with students and the development of more complex knowledge. Countries which support formative assessment emphasis the role of internal evaluation and prior knowledge developed control and therefore assessment for learning more. Thus, teachers' trainings are focused on searching for evidences of learning and on different forms of learning encouragement.

Formative assessment does not suppose that a grade should only be the teacher's matter in order to inform a student about it. It is formed by a mutual dialogue, which presumes that a student self-evaluates first. Teacher communicates well with students to improve the quality of education. This could be achieved by developing his/her personal abilities to engage more perception channels, multi-presentation, multi-dimensional thinking and focus on students' personal growth as well as by assessing multiple forms of knowledge, which is not only objective but also subjective. We should mind what to include in communication and what to exclude from it, and what to take into consideration and what not, we should consider as well the well-being. The form of communication indicates whether a teacher is interested mainly in student's permanent knowledge resulting in fundamental changes in student's personality or only in superficial and short-term knowledge. Likewise, it can be observed whether a teacher acts as student's partner, assistant, in short, whether (s) he performs all four teaching types according to Delors.

ABSTRACT

Our research focused on the analysis of the impacts of the formal nutrition education on the nutrition knowledge of the 6th graders of nine-year primary school pupils, as well as the role of home economics as a school subject. The purpose of the research was to determine the level of nutrition knowledge of the pupils at the beginning and at the end of the school year. The research study involved 28 home economics teachers and 630 6th graders of nine-year primary schools in Slovenia who attended home economics classes in 2006/2007 and received formal education on nutrition. The pupils' nutrition knowledge was assessed by a written test given at the beginning and at the end of the course on nutrition. The results of the research showed that nutrition education has effects on the pupils' knowledge. However, no statistically significant differences in the knowledge between boys and girls were found and nutritional education did not significantly influence the dietary habits of the pupils.

Keywords: *nutrition education, nutrition knowledge, pupils, dietary habits.*

INTRODUCTION

Nutrition education, which takes various forms of formal and informal education, can significantly change nutrition behaviour and change dietary habits of children (Lytle et al., 1996; Powers et al., 2005; Reynolds et al., 1999; Worsley, 2002).

Thus, we may assume that providing topics on nutrition in primary schools can contribute to forming healthy life styles of children and young persons undergoing compulsory formal education.

In view of the risk factors, which are due to improper diets of children and young persons, the researchers agree in that nutrition recommendations and school syllabi should be adapted to cultural characteristics of a particular group. Nutrition strategies aiming at children and young persons should therefore become a priority at the national level (Rodrigues et.al., 2004; Schneider, 2000).

The Slovene Food and nutrition action plan 2005 – 2010), adopted in 2005, envisages numerous measures for the promotion of healthy nutrition of children and young persons aiming to acquire healthy nutrition habits and change nutrition attitudes. The plan proposes actions for promoting healthy nutrition both, for children and young persons as well as parents. The activities are planned to be implemented through the mass media, in schools, student residences and local communities. Thus, the program of nutrition policy establishes the implementation of programmes for general promotion of health, healthy nutrition and healthy life styles to all training and education institutions and introduces these topics into school curricula of elementary, vocational and secondary schools (Maučec Zakotnik et al., 2005).

In the curriculum of nine-year primary schools various topics on nutrition are included, mainly offered through science subjects. Thus, for instance, the syllabi for the compulsory subject of Home Economics and elective subjects Modern ways of food preparation, and Nutrition which are taught in the third triad of the nine-year primary schools provide numerous teaching topics for acquiring knowledge and skills in nutrition. The nutrition education is most intense in the 6th grade and is offered within the Home Economics course (Koch & Kostanjevec, 2005)

Most studies in which the researchers analysed the impact of nutrition education on nutrition behaviour of children have been focused on the analyses of the effects of nutrition education and were targeted at specific populations and educational contents (Jaycox, 1983; Salminen et al., 2005; Barlov & Dietz, 1998).

Persons who undergo the process of informal education are usually internally motivated. Consequently, this has positive effects on the outcome of education. On the other hand, in formal education, which is compulsory for all children, motivational levels are different and prior to education children have already developed certain nutrition behaviour and dietary habits which come as a result of biological and internal or external psychological and social factors.

The results of research, in which the impacts of nutrition education on nutrition behaviour and nutrition knowledge were studied and analysed, have brought different results. Understanding different factors which influence nutrition behaviour of children is the first step to forming efficient measures which may change nutrition behaviour (Cullen et al., 2000).

Some studies confirm the hypothesis that it is possible to improve nutrition behaviour and nutrition knowledge by proper educational programmes (Powers et al., 2005; Worsley, 2002; Reynolds et al., 1999). Axelson et al. (1985) studied the correlation between the nutrition knowledge and nutrition behaviour in adults, children and young person to find out that the correlation was very low (r = 0.10).

The results of analyses of the impacts of formal education on nutrition knowledge and nutrition behaviour of children and young persons can, to a certain extent, prove suitability and efficiency of educational programmes and teaching aims and indicate how nutrition knowledge has improved, or influenced nutrition behaviour of children.

The purpose of our research was to find out how suitable the nutrition education in elementary schools in Slovenia is.

By analysing variables at the beginning and at the end of educational process we could measure and analyse the impact of formal nutrition education on the nutrition knowledge of pupils. In addition, we were able to observe the changes in their nutrition habits. By determining the level of changes of individual variables due to nutrition education we could critically evaluate the impacts of nutrition education on nutrition behaviour of pupils.

METHODS AND RESULTS

Sample

The purpose of our research was to analyse nutrition knowledge and nutrition habits of eleven-year-olds from 28 schools in Slovenia. The research sample included 630 pupils who attended the course of Home Economics in school year 2006/2007. We administered the first knowledge test in September 2006, at the beginning of the course, and in May 2007 after the completion of the course. The course was compulsory for all pupils.

Nutrition education

It was found out that in all schools participating in the study, the home economics courses were in agreement with the curriculum for the 6^{th} grade of elementary nine-year programme. In some schools courses were adapted to the specific conditions of a school and their programmes. According to the curriculum, home economics course for 6th graders takes 52.5 hours.

Table 1. Number of hours of home-economics courses and number of hours devoted to nutrition topics in 2006/2007

	Home economics (hrs)	**Nutrition topics (hrs)**
M	50,7	38,6
Min	15,0	26,0
Max	55,0	45,0

From the Table 1 we can see that on the average children had 50.7 hours of home economics, and 38.6 hours were devoted to nutrition topics. Teachers applied different teaching methods, mainly group work. Children worked either in pairs or in small groups, less frequently individually, or the teacher presented the topic frontally.

Testing of knowledge

The pupils' nutrition knowledge was tested by a written test given at the beginning and at the end of the course on nutrition. The test included 27 test items. Test items covered thematic units and were designed according to the knowledge standards prescribed by the home economics syllabus. Thematic units are listed below:

- nutrients and energy,
- energy value of foodstuffs,
- nutritional value of foodstuffs,

- ingredients in foodstuffs,
- foodstuffs groups,
- groups of foodstuffs according to the content of nutrients,
- energy needs,
- the role of nutrients in human body,
- impacts of nutrition on human health,
- nutrients and human organism,
- nutrition recommendations,
- planning a healthy diet.

In the test we used different types of questions to test assess levels of knowledge according to Bloom's taxonomy. The maximum number of points which could be achieved in the knowledge test was 27.

Nutrition habits

Nutrition habits of children were analysed on the results of a food frequency questionnaire. The measurement instrument for identifying nutrition habits was adapted to HBSC questionnaire (Stergar et al., 2006).

Statistical methods

The data were analysed by statistical software SPSS. In analysing the results of the knowledge test we used the t-test statistical method for dependent and independent variables. The impact of newly acquired knowledge on nutrition habits of children was measured by calculating partial correlation coefficient. In statistical interpretations we considered a 0.050 risk factor.

RESULTS

Nutrition knowledge

The correct answers in the knowledge test were assigned a one point value, and wrong answers a zero value. The maximum number of points was 27. We calculated the total number of points achieved by each individual, separately for the first and the second knowledge test. If we compare the mean values of points collected during the first and the second knowledge test, we can see that during the second test children achieved statistically more significant number of points compared to the first test. In the first test children collected 14.60 points on the average, while in the second test they achieved 15.91 points (Table 2). From the data in Table 2 we can infer that children's knowledge improved after they have taken the course on nutrition.

Table 2. Comparison of mean values of the points collected in the first and the second test

	N	M[a]	SD	t	P
First knowledge testing	524	14.60	3.428	-8.174	0.000
Second knowledge testing	524	15.91	4,008		

[a] maximum number of points possible = 27

Analysis of nutrition knowledge by gender

If we compare the mean values of the points achieved during the first and the second knowledge test we can see that there are no statistically significant differences between the boys and girls in the value of total points achieved during testing. The results are presented in Table 3 below.

Table 3. Mean values of points achieved during the first and second knowledge test by gender

	Gender	N	M[a]	SD	t	P
First knowledge testing	boys	305	14.40	3.569	- 0.758	0.449
	girls	291	14.62	3.460		
Second knowledge testing	boys	285	15.57	4.050	- 1.134	0.257
	girls	269	15.96	4.061		

[a] maximum number of points possible =27.

The average number of points the boys achieved during the first testing was (M = 14.52). The result is statistically significantly different from the results the boys achieved during the second testing (M = 15.81). From this we may infer that the boys improved their nutrition knowledge (Table 4).

Table 4. Comparison of the mean values of points achieved during the first and second knowledge testing – boys

	N	M[a]	SD	t	P
First knowledge testing	268	14.52	3.471	-5.835	0.000
Second knowledge testing	268	15.81	3.909		

[a] maximum number of points possible =27.

In the group of girls, the average number of points achieved during the first knowledge testing was (M = 14,68), and is statistically different from the results the girls achieved during the second testing (M = 16,01). As we can see from the results in Table 5 below, the nutrition knowledge of girls improved.

Table 5. Comparison of mean values of total points achieved during the first and second knowledge testing – girls

	N	M[a]	SD	t	P
First knowledge testing	256	14.68	3.386	-5.715	0.000
Second knowledge testing	256	16.01	4.114		

[a] maximum number of points possible =27

Impact of education on nutrition habits

Using the method of partial correlation we excluded the linear impact of nutrition knowledge at the beginning of the school year to the correlation between variables in the knowledge at the end of the school year and frequency of meal consumption, or particular foodstuffs consumption.

The analysis of the results shows that the knowledge which resulted from the course on nutrition had no significant impact on daily meal consumption among the children tested. While correlations are statistically significant, and correlation coefficients are positive, they are very low (r < 0.20), which means that correlations are statistically negligible and there are no statistical correlations (Table 6).

Table 6. Partial correlation between nutrition knowledge and food consumption frequency (K2T2.K1).

Meal	Nutrition knowledge (2nd knowledge testing)	
	r	P
Breakfast	0,040	0,188
Morning snack	0,141	0,001
Lunch	0,073	0,054
Afternoon snack	0,119	0,005
Dinner	0,084	0,032
TOTAL meals	0,151	0,001

Legend:
K1 – knowledge (1st test)
K2 – knowledge (2nd test)
T2 – food consumption frequency (2nd survey)

By calculation of partial correlations between the fast-food consumption frequency and nutrition knowledge of children at the end of the school year showed a negative correlation but statistically significant for the consumption of french fries and hamburgers, as well as for the total consumption of food categorised as fast food. In all cases described we have established that the negative correlation is negligible and that there is no statistical correlation (r < 0.20). Negative statistical correlation shows that children with better nutrition knowledge less frequently consume fast food compared to other children with poor nutrition knowledge (Table 7).

Table 7. Partial correlation between nutrition knowledge and frequency of fast food consumption (Z2P2.Z1).

Food	Nutrition knowledge (2nd testing)	
	r	P
Sandwich	-0.016	0.365
Pizza	-0.071	0.059
French fires	-0.100	0.014
Hamburger	-0.088	0.027
Fast food TOTAL	-0.006	0.450

Legend:
Z1 – knowledge (1st testing)
Z2 – knowledge (2nd testing)
P2 – frequency of meals (2nd survey)

We have also analysed the impact of nutrition education on the consumption of particular foodstuffs in children. The calculation of partial correlation showed that for some types of food (e.g. meat, cereals) there is a negligible statistically significant correlation ($r < 0.20$) between the nutrition knowledge acquired and frequency of a particular food consumption. By calculating partial correlations we found out that there is also a negligible negative statistical correlation between the knowledge acquired and frequency of consuming soft drinks, energy beverages or alcohol.

CONCLUSION

As already established by the authors Conner and Armitage (Conner & Armitage, 2002), education and nutrition knowledge do not necessarily have any direct effect on the nutrition behaviour of individuals, however this may significantly influence the attitudes and other psychosocial factors which influence nutrition behaviour.

It was found out that, statistically, the knowledge of pupils significantly improved after they had finished the learning process. The analysis of the knowledge showed that pupils know the basic principles of healthy nutrition which they have already acquired at the lower levels of their schooling. Considering how nutrition topics are presented in Home Economics as a school subject, we can conclude that Home Economics mainly focuses on acquiring skills and less on acquiring theoretical knowledge. In nutrition education, the sixth graders of the primary schools are faced with concepts which, according to their level of cognitive development, are too difficult to understand and this may have resulted in their knowledge. For example, to understand the role of nutrients, or topics related to food energy values, pupils need to employ abstract and hypothetical mind operations which may be very demanding at this age. We did not find any statistically significant differences in the knowledge between boys and girls. We believe that larger differences may be expected in higher grades of primary school.

One of the operative aims of the home economics curriculum is that learners, after completing the course on nutrition, should be able to analyse human needs for nutrients and energy in food, and should be able to know the nutrient value of foodstuffs, and thus be able to classify food into groups. Considering the cognitive level of children who participated in the study we can expect that children become capable of dealing with more complex problems at a later stage, i.e. in higher years of compulsory education. Therefore, it is necessary to integrate nutrition topics into the syllabi in the last triad of elementary schooling. The existing syllabi, which contain topics on nutrition, need to be adapted to the corresponding cognitive development level of children, and children need to be introduced with the latest findings in nutrition science, where particular concepts which are used in nutrition education need to be clearly defined.

By determining the level of changes of particular variables measured due to the influence of nutrition education it is possible to critically evaluate the existing nutrition topics and curricular aims for elementary schools. Formal nutrition education, which is carried out at the 6th grade of elementary schools in Slovenia, has proved to be successful from the aspect of acquisition of new nutrition knowledge. A detailed analysis of knowledge test results showed that general knowledge about nutrition is good, while children lack the knowledge to be able to explain more complex problems related to healthy nutrition.

Based on our results we propose that there should be more hours devoted to nutrition education in schools, and that nutrition education should be provided throughout the course of elementary school programme. Only in this way we can expect better quality and permanence of the knowledge acquired, which would consequently lead to the formation of healthy nutrition habits of children. Nutrition education needs to be carefully planned and continuously provided, also beyond elementary schooling, i.e. at the secondary and tertiary level. What is important is that we allow for continuous upgrading of the knowledge and bring in interdisciplinary approach. Nutrition education should be of national interest if we want to improve nutrition habits and lifestyles of Slovenian people.

Therefore, the aim of nutrition education should be to qualify children for problem solving in questions related to nutrition, which means developing analytical and logical thinking. Only a sound and reinforced nutrition knowledge can contribute to the formation of positive attitudes towards healthy nutrition among children, which later, during the period of adolescence, will result in the formation of healthy nutrition habits, meaning that there is a lesser chance for children to become influenced by their peers and acquire bad nutrition habits.

Nutrition education of young persons requires activities and methods which would promote and reinforce self-efficacy in terms of healthy eating. Education will only become more efficient if we are able to remove the factors which hinder the development of healthy nutrition habits of young persons and enable access to healthy food (Gracey et al., 1996).

Worsley (2002) found out that while on the one hand nutrition education is necessary, it alone is insufficient to bring changes into nutrition behaviour of persons. Children need to be constantly encouraged to consume healthy food, which means that suitable environment needs to be created. Equipped with good nutrition knowledge, children will be able to develop suitable and good quality life styles. Consequently this will help them to take responsibility for their continuous personal development and hence the development of the society as a whole.

GHANAIAN URBAN AND RURAL JUNIOR SECONDARY SCHOOL PUPILS' OPINIONS OF THE ROLE OF SCIENCE AND TECHNOLOGY IN SOCIETY: IMPLICATION FOR SCIENCE, TECHNOLOGY AND SOCIETY EDUCATION

Ishmael K. Anderson

University of Education, Winneba, Ghana

ishkandy@yahoo.com

ABSTRACT

The paper probes into how Junior Secondary School (JSS) pupils in the Central Region of Ghana perceive the role and function of science and technology in society. In the year 2003, 613 and 414 final year pupils from urban and rural schools respectively were used for the study. Subjects responded to one of the themes of a standardized Relevance of Science Education (ROSE) survey questionnaire of which the items are statements about some aspects of science and technology issues, all on 4-point Likert-type scale. An independent sample two-tailed t-test was used to determine the differences in the items' mean values between the two groups at $p \leq 0.05$. Findings were that urban and rural pupils expressed almost similar views about issues of science and technology. However, very few differences in opinions between urban and rural pupils were found to be statistically significant. The paper concludes that the emotional disposition of pupils towards the role and function of science and technology in society might translate into high motivation in pupils for any sound science, technology and society (STS) education.

Keywords: *Ghana, urban and rural settings, school pupils, STS education, science curriculum, geographical background.*

INTRODUCTION

Any country striving to develop in order to raise the standard of living of its population and maintain a balanced economy must as a matter of necessity adopt science and technology as the basis for achieving sustainable development. Science and technology continues to play an important role in the areas of food production, protection against and treatment of diseases and waste management. In these areas, engineers and technologists with their expertise may have the opportunity to help and make the world a better place to live (Schreiner, 2006). Ghana, as a nation, recognizes the importance of science and technology in national development. Hence, since the attainment of independence, successive governments have endeavoured to make science and technology a basis for the country's development (Anamuah-Mensah, 1994).

According to Sjøberg (2002a), education in science and technology are the most important areas of the curriculum to enable people to make sense of the world and to use the resources at hand. Therefore, for Ghana to develop there is the need to support the rapid development of scientific and technological literacy among all individuals. Science and technology education should therefore be given high priority in the school curriculum.

As a result of the increasing consciousness of the importance of science and technology in social and environmental issues, there have been attempts in Ghana to initiate science, technology and society (STS) programmes in all educational levels. These efforts to foster STS approaches to school science and related curriculum fields appear to have met challenges. It appears some of the challenges are that as science and technology are becoming increasingly important in changing society and people's lives, many pupils simultaneously experience school science as irrelevant to their present and future lives. It has also been mentioned in a study that STS materials have not changed the phase of school science to any appreciable level but rather served the function of supporting and enriching otherwise conventional school science courses (Jenkins, 1992). This is because efforts to identify courses, titles and special projects which have common features of STS to embrace all backgrounds or social class appear to meet with difficulties.

It is a fact that the current practices in science and technology education have the goal to develop scientifically literate individuals who are able to use their knowledge in their everyday decision-making and not to turn everyone into a scientist. These individuals are to appreciate the values of science and technology in society and understand their limitations. However, another challenge confronting science and technology education is how to change our goals from that of academic preparation for science careers for a few individuals to start individuals on the road to critical thinking, to better problem-solving ability, and to become better citizens in this increasingly technical world (Yager, 1996). Furthermore, in the face of the current global trends, there is a demand for science and technology education to emphasize preparing all pupils to engage successfully with science and technology in their own, everyday lives, as well as to participate knowledgeably in important science and technology-related issues. This calls for a shift from an academic curriculum design towards a social curriculum design. With this, the scientifically literate person can use concepts of science, technology and ethical values in solving everyday problems and making responsible everyday decisions in everyday life.

Pupils in general appear engrossed in current technological developments and perhaps use them to see the importance and relevance of science concepts. However, they also appear to recognize the strengths and limitations of science and technology for advancing human welfare (Yager, 1996). Consequently, relevance of STS is not a means to technology education since the latter focuses on the teaching of the technical aspect of technology and it is, therefore, not considered among the approaches to STS education (Pacey, 1983).

Equity with respect to social class or geographical background is on a high list of political, social and educational concerns in Ghana. The urban and rural communities in Ghana are in the extremes with respect to most statistical indicators, like educational level, income, and occupational pattern. The perceived isolation of rural schools and a low population density create an additional set of challenges to science education. A study by Zuniga, Olson and Winter (2005) indicates that a sense of isolation and low population density make opportunity fewer for pupils in rural schools. It is even argued that the lack of educational resources, most often occurring in rural communities, has a demoralizing effect on teachers to teach science (Fredua-Kwarteng & Ahia, 2005). Children growing up in these two different communities represent great disparities in the Ghanaian context. This might expect them to demonstrate very different interest profiles at school science. However, in a world filled with the products of science-based technology, everyone needs to be equipped with skills to engage intelligently in public discourse and debate about important issues that involve science and technology in a society. Such skills can be realized through a high quality STS education.

Hence, it is justifiable to elicit the opinions of both urban and rural school pupils on how they perceive the role of science and technology in society, including opinion patterns that might emerge. This is because empirical evidence shows that the level of technological development in a community or country is a key factor for explaining the expectations people have of further developments in science and technology (Schreiner, 2006).

METHODOLOGY

A descriptive research design was used to survey urban and rural JSS pupils' opinions about the impact of science and technology on society.

POPULATION AND SAMPLE

The target population was all urban and rural junior secondary school (JSS) pupils at the terminal class (JSS3 or ninth grade) of the compulsory schooling in the Central Region of Ghana in the year 2003. One JSS from an urban area and another one also from a rural area in each of the twelve (12) districts of this region were considered. Within these schools, a sample of 613 and 414 pupils were selected from urban and rural settings respectively, to participate in this study.

The choice of JSS3 is based on the recognition that at this level most of the pupils would have reached the age of 15 years. At that age pupils are expected to be mature and hence likely to undertake conscious reflections on their interest, priorities and attitudes to comprehend science and technology-related issues. In Ghana, it is also the age when many educational and curricular choices are made. Therefore, it is likely that at that age pupils will give consistent responses to the questions and thereby enhance the reliability of the data.

DATA COLLECTION AND ANALYSIS

One of the subsets of a standard ROSE questionnaire labelled G and with a theme "My opinions about science and technology" (Appendix A) was used to collect a purely quantitative data. The 16 items of this subset tapped into pupils' perception about the role and function of science and technology in society, as well as their expectations of science and technology. The items are on issues about science and technology, each on a 4-point Likert scale from 'Disagree' to 'Agree'. The Likert scale which was used is regarded in this study as quasi-interval scale (Schreiner, 2006). This assumption has an advantage in that, data in such an interval scale can be manipulated by addition and subtraction, and therefore can be used in the most common statistical procedures (Ary, Jacobs & Razavieh, 1996 cited in Schreiner, 2006). The acceptance to use the Likert scale as a method of scaling in this study is based on its widely mentioned use in the literature (Robson, 2002; Neuman, 2000; Gable & Wolf, 1993). It is also the most common method of scaling in international surveys like TIMSS, PISA and Eurobarometer. A 'neutral' point with a mean score of 2.5 is the middle mark on the 4-point Likert-type scale, which represents a position in their responses. This position indicates an option by majority of the pupils but not all, where they neither disagree nor agree to an item.

Data obtained using the standard ROSE questionnaire on the above theme were analysed through the use of SPSS version 12.0.1 for Windows (SPSS Inc., 2003) and Excel. Descriptive statistics was conducted on data obtained to provide documentation on general expectations of pupils for science and technology. An independent sample 2-tailed t-test was used to explore the statistical significance of the differences in the items' mean at a conventional $p \leq 0.05$ level of probability to report whether significant differences existed between the groups of pupils' responses by geographical location.

ROSE PROJECT

The ROSE is an international cross-cultural comparative research project basing its theoretical framework on the affective domain aspects of science and technology learning with about 15 year-old cohorts. Information about the project including questionnaire and countries involved is found in Schreiner and Sjøberg (2004) and also at the website (http://www.ils.uio.no/forskning/rose/).

RESULTS AND DISCUSSION

The views expressed by both urban and rural junior secondary school pupils concerning the roles science and technology play in a society appeared to be positive. The positive views were shown clearly in their responses on all the listed issues about science and technology, which had mean values greater than 2.5. The mean range of responses to each of the statements for urban pupils was from 3.55 to 2.63 and from 3.58 to 2.62 for rural school pupils. Based on these mean values, it appears both urban and rural school pupils have high expectations for science and technology.

In Table 1, the results are presented in an increasing order of popularity of opinion among urban and rural school pupils. The most popular expressed opinions are considered and then followed by the less frequently mentioned issues about science and technology in society. All the numbers are mean values of pupils' responses to each of the roles and functions of science and technology in society. However, the mean values greater than 3.0 are presented for both urban and rural pupils in Table 1.

Urban and rural school pupils' responses appeared to emerge in a similar pattern. Most pupils from both urban and rural communities appeared confident about the possible achievements of science and technology. The majority of the urban and rural pupils seemed to have a strong belief in the following aspects of science and technology (see Table 1).

Though there are some differences in opinions between urban and rural pupils about science and technology, most of the differences appeared to be of no educational significance. Both groups held similar positive views on the list of aspects of science and technology. However, five out of sixteen items showed statistically significant differences with p-value less than 0.05 (Appendix B). These significant differences are also shown in Figure 1. On the average, there were three aspects of science and technology issues, which urban school pupils agreed more than their rural counterpart. For the rural pupils, they had more belief in two aspects of the science and technology issues.

Table 1 Urban and rural pupils' most important aspects of science and technology in society (mean score value >3.0). Mean values sorted in descending order. Items appearing on both lists are in boldface.

	Urban pupils' opinions	Mean
G1	**Science and technology are important for society**	**3.55**
G4	**Science and technology make our lives healthier, easier and more comfortable**	**3.44**
G11	**A country needs science and technology to become developed**	**3.36**
G3	**Thanks to science and technology, there will be greater opportunities for future generations**	**3.35**
G5	**New technologies will make work more interesting**	**3.33**
G2	**Science and technology will find cures to diseases such as HIV/AIDS, cancer, etc.**	**3.21**
G13	**Scientists follow the scientific method that always leads them to correct answers**	**3.19**
G12	**Science and technology benefit mainly the developed countries**	**3.10**
G6.	**The benefits of science are greater than the harmful effects it could have.**	**3.08**
	Rural pupils' opinions	Mean
G1	**Science and technology are important for society**	**3.58**
G4	**Science and technology make our lives healthier, easier and more comfortable**	**3.40**
G11	**A country needs science and technology to become developed**	**3.37**
G5	**New technologies will make work more interesting**	**3.34**
G3	**Thanks to science and technology, there will be greater opportunities for future generations**	**3.26**
G2	**Science and technology will find cures to diseases such as HIV/AIDS, cancer, etc.**	**3.23**
G6	**The benefits of science are greater than the harmful effects it could have**	**3.09**
G13	**Scientists follow the scientific method that always leads them to correct answers**	**3.04**

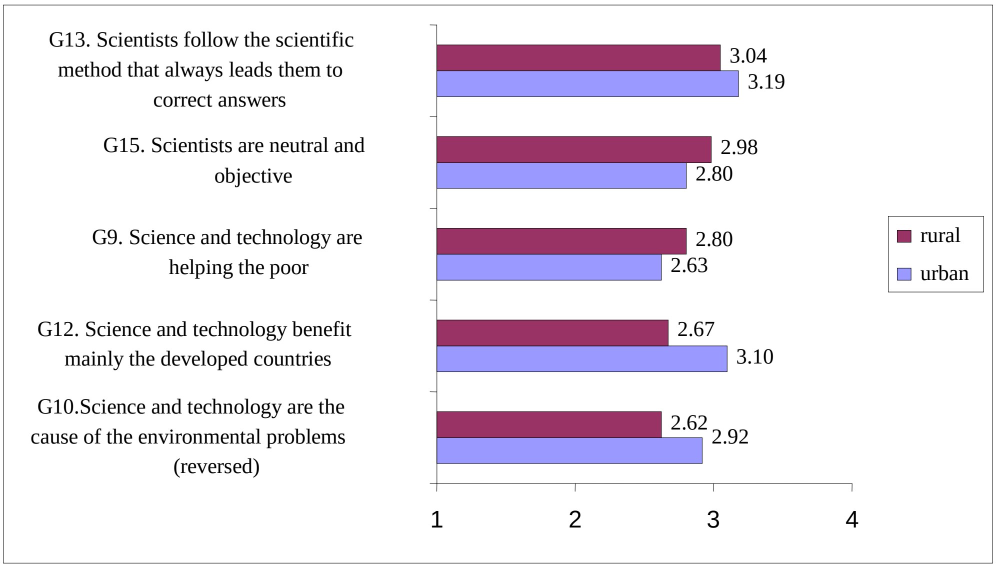

Figure 1. Statistically significant differences (p<0.05) in opinions for rural and urban school pupils. Mean values sorted in descending order for rural pupils.

The responses given by pupils on science and technology issues showed that both urban and rural school pupils had high regard for science and technology. This is because the mean values of their responses appeared to indicate that they strongly agreed with a number of issues concerning science and technology in society. Some of their perceptions of science and technology were that science and technology are important for society and also can make our lives healthier, easier and more comfortable. These perceptions might explain why the majority of urban and rural pupils in this study demonstrated in their responses that a country needs science and technology to become developed and that new technologies will make work more interesting.

Schreiner and Sjøberg (2007) and also Schreiner (2006) have all indicated in their studies that in developing countries, pupils' immediate concerns about the application of science and technology are for general improvement and welfare of their societies. Perhaps this observation might be one of the reasons that pupils' opinions surveyed showed a great respect for science and technology. With regard to the respect for science and technology, they seemed also to have a strong belief that through science and technology there will be greater opportunities for future generations. Scientists were seen as very brave and intelligent people who follow the scientific method that always leads them to correct answers. Furthermore, there was the belief that scientists can help people by finding cures to diseases such as HIV/AIDS and cancer. An interesting aspect of their responses was that science and technology was seen as having more benefits than harmful effects. These high expectations of pupils for science and technology appear to link well with their high levels of interest to learn science and technology-related issues at school (Anderson, 2007).

As indicated earlier, the beliefs in several aspects of science and technology shown by pupils in the poor and underprivileged part of the world have been mentioned in some studies (Sjøberg, 2000; Sicinski, 1976). The results from this study of both urban and rural pupils from Ghana revealed that pupils from these two different geographical areas held positive views about issues of science and technology. They appeared to show no emotional disposition towards the possible negative effects of the advancement in science and technology. Perhaps, their focus is on how science and technology can improve the general welfare of society and therefore, their immediate concern might not be associated with some of the possible adverse effects of science and technological application in society. Against this background, the perceived negative characteristics associated with scientists are not likely to emerge at early stage of schooling. This assertion is in line with some studies in science education which revealed that scientists continue to enjoy the position of respect in the developing societies (Sjøberg, 2000; 2002b).

In view of the fact that urban and rural school pupils are from two different environments, the differences in their opinions about science and technology issues in society were not pronounced. Issues that were perceived to be important by one group were also of equal importance to the other. Both urban and rural pupils perceived that scientists are neutral and objective and that science and technology are helping the poor.

When opinions were sought between urban and rural pupils about whether science and technology had played any role in the development of the world, the responses revealed a large difference in opinion between the two groups. Urban pupils agreed more to the statement than rural pupils that science and technology benefit mainly developed countries (mean value was 3.10 as against 2.67 for rural pupils). Urban school pupils also were less in support of the statement that science and technology are the causes of the environmental problems. This statement, however, was reversed and the mean values were 2.92 and 2.62 for urban and rural school pupils respectively. A mean response value of 2.62 appears to indicate that most rural pupils were somehow indifferent to the statement since a value of 2.62 is on the right and closer to the neutral response value of 2.5.

For rural pupils, the stronger belief that science and technology are helping the poor appears to correlate well with their lesser belief that science and technology benefit mainly developed countries. On the other hand, urban pupils were less in agreement that science and technology are helping the poor. This also seems to correlate well with their strong perception that science and technology benefit mainly the developed countries. Pupils in rural communities are confident that advancement in science and technology might have the capability of reducing incidence of poverty and other challenges.

IMPLICATION FOR STS EDUCATION

Looking at these responses as the true reflections of their opinions about science and technology, certainly, such views of the pupils could influence their motivation and willingness to engage in schooling that is more associated with science and technology. Since the JSS is a terminal point for the formal education of most pupils, it is at this point that scientific knowledge and attitudes need to be strengthened. A key concern for the reworking of the science curriculum when it is opened for negotiation is to re-establish relevance, meaning and significance of science learning based on changes in science and technology and their role in society.

In this study, it has become obvious that the young urban and rural learner may have developed awareness and appreciation of scientific and technological activities, and interdependence of scientific, socio-economic and technological changes in Ghana and other countries. An important thing now is to identify courses, topics and projects to feature well in STS education that should interest both groups of learners. This could be done by bringing faculty from social studies and science together to mount courses, which meet the requirements in science or in social studies. Interestingly, both groups of learners, irrespective of their backgrounds, have demonstrated in the opinions a common interest in science and technology issues. Hence a search for courses and topics in STS education might not meet with much difficulty. In these courses and topics pupils are likely to attain and retain many skills and competencies defined as science literacy since they meet their interest. Such skills and competencies could be difficult to develop as a result of study in standard (traditional) science courses. This is because in STS classes, pupils are expected to be motivated to see science concepts as personally useful and can relate them to new situations. However, the practical situation in rural areas in Ghana in the face of our economy may challenge the enthusiasm for rural school pupils to participate equally in STS education as their urban counterpart. Educational policy makers need to capitalize on such interests of pupils towards science and technology issues. These educational policy makers need to rethink curriculum and resources that will be more accessible within STS education in this era of science for all. All these efforts are aimed at producing scientifically literate people that can compete effectively in a globalized knowledge-based economy.

ABSTRACT

A case study on teacher learning to teach Nature of Science

This paper reports the case of a teacher, Gloria, about her learning in the first nine months of a Teacher Professional Development (TPD) program which aims at preparing teachers teaching Nature of Science (NOS) in the new curriculum reform in Hong Kong. Upon reflection of her learning, Gloria highlighted the importance of leaving enough time for student's discussion and the importance of "wait time" in teaching students about nature of science. When Gloria was asked to identify ideas about NOS teaching that she would like to share with other teachers in a study group meeting of the TPD program, without hesitation she picked on the issue of "not to hurry things". This paper examines how this important learning for Gloria is related to the explicit and reflective approach advocated in the literature on teaching of NOS. The processes of how Gloria came to learn about this in the TPD program will be presented and discussed. Lastly, implications are drawn regarding the design of an effective TPD program for helping teachers to learn how to teach NOS.

Keywords: *Nature of Science, Teacher Professional Development*

INTRODUCTION

Understanding nature of science (NOS) has long been regarded as a major component of scientific literacy and an important learning objective of science curricula in many countries (American Association for the Advancement of Science [AAAS], 1989, 1993; Council of Ministers of Education, Canada [CMEC], 1997; National Research Council [NRC], 1996). In line with this international trend, recent development of science curricula in Hong Kong has seen a shift from the predominantly content-focused goal to a wider goal of promoting understanding of nature of science (NOS). This poses a host of problems and challenges in preparing teachers for this new curriculum reform. For example, various studies consistently point to teachers' inadequate understanding of NOS (Lederman, 1992). Other studies also pointed out that, even teachers with sufficient NOS understanding, it is not automatically and necessarily translated into classroom practice (Lederman, 2007). Teachers are, in general, lack of the relevant pedagogical skills for the teaching of NOS. In view of this, a 2-year long teacher professional development (TPD) program has been set up to prepare teachers in Hong Kong for the teaching of NOS. The aim of this paper is to report one of the key learning of a teacher, Gloria, in this TPD program: how Gloria have come to grips with her important learning of "not to hurry things" in the process of teaching NOS; and how various factors in the program had contributed to her learning.

THEORETICAL UNDERPINNINGS

Instead of a complete review of all the relevant literature, this session presents studies that informed the design of the present TPD program.

SEARCHING FOR AN EFFECTIVE APPROACH OF TEACHING NOS

Much research efforts have been placed to improve teachers' conceptions of NOS for approximately fifty years. Some initial TPD programs which attempted to improve teacher's NOS understanding include the work of Welch and Walberg (1968). They investigated the usefulness of a summer institute program for physics teachers. Lavach (1969) discussed the historical development of some science concepts in an in-service program; and Billeh and Hasan (1975) conducted a four-week courses which included 12 lectures related to NOS. Lederman (1992), in his review, summarized that these efforts to improve teacher's understanding have met with some success whey they have discussed historical aspects of scientific knowledge or drawn direct attention to the NOS.

Later on, Abd-El-Khalick and Lederman (2000) conducted another comprehensive review. The aim of this latter review was to compare the 'effectiveness' of two nearly contradictory attempts to improve teachers' NOS conceptions: implicit and explicit approach. Implicit, as implied, means that the understanding of NOS is a result of engaging the learner in scientific inquiry, participating in science-related activities and/or doing science. Whereas, explicit is an approach which intentionally draws learners' attention to relevant aspects of NOS through instruction, discussion, questioning and written work following classroom activities. Based on the studies reviewed, Abd-El-Khalick and Lederman concluded that the explicit approach is relatively more effective in promoting teachers' NOS conceptions than the implicit one. Indeed, other evidence is accumulating to support this claim that an explicit approach, especially with a reflective component, is an effective way in improving teachers' views of NOS (e.g. Abd-El-Khalick, 2001; Abd-El-Khalick & Akerson, 2004; Bell, Lederman & Abd-El-Khalick, 2000; Irwin, 2000). To follow the above suggestions, the present TPD program paid explicit and direct attention to the NOS.

TEACHER PROFESSIONAL DEVELOPMENT PROGRAMS FOR IMPROVING NOS INSTRUCTION

Three recent TPD programs which informed the design of the program described in the present study are discussed below.

Three-year program on elementary teachers' view and practice

One of the studies is by Akerson and Hanuscin (2007). The study aims at tracing the influence of a 3-Year TPD Program on elementary teachers' view of NOS, the instructional practice to promote students' appropriate NOS views, and the influence of participants' instruction on elementary students' NOS views. The design of the TPD program mainly draws upon Bell and Gilbert's (1996) science teacher development model. The model emphasizes three components: (a) personal development in which the teacher must be aware that there is a need for professional development and acknowledge the desire to acquire new ideas or strategies; (b) social development in which the teachers have opportunities to discuss ideas with other teachers, and to collectively renegotiate what it means to teach science and be a teacher of science; and (c) professional development in which the teachers are supported in implementing the new ideas and strategies in their classroom practice, drawing on the changes they make personally and socially. These three components are viewed as essential to building on teachers' commitment to enact changes within their own classrooms and professional communities. Some other characteristics of successful teacher development model employed in this study include providing enough time to allow for acquisition of new views along with practice, feedback, follow-up, allowing the teacher to reflect on the new idea or implementation of the new skill, and allowing the teacher to see the new skill or strategy in practice (Henriques, 1998; Loucks-Horsley, Hewson, Love, and Stiles, 2003). The TPD program finally developed consisted of a series of monthly half-day workshops, as well as regular on-site classroom visits by project staff. Results indicated that the teachers (as well as the students they taught) showed positive changes in their views of NOS and improved science pedagogy. In the discussion part, the authors reported that all aspects of the program had influenced teachers to varied degrees. The individual support for teachers was found to be a critical element of their social development. Participated teachers also reflected that the monthly workshops also influenced their change in NOS views, as well as their instructional practice.

In the present study, due attention will be paid to the three components of Bell and Gilbert's TPD model as adopted in Akerson and Hanuscin's study. First, teachers participating in the present study are likely to be those who feel insecure about NOS teaching but committed to improve their science teaching (as they all joined the present study on a voluntary basis). This, according to Bell and Gilbert's model and supported by Akerson et al's study, is an important first step in their personal development. Hence, the above criterion was considered in selecting teachers for this study. To address the second component in Bell et al's model, i.e. social development, teachers in the present study have had ample opportunities to engage in discourse with peers regarding their practice in study group meetings and during workshops. To address the third component (i.e. professional development), support from facilitators (who are experienced science educators) have been offered to teachers with new ideas and strategies to trial out in their own classroom while they are learning how to teach NOS.

Project ICAN

Project ICAN (Inquiry, Context, and Nature of Science) was a five-year TPD project funded by the National Science Foundation in the United States (Kim, Ko, Lederman & Lederman, 2005). Of interest and relevant to the present study is its requirement of the participants to undertake some microteaching sessions in order to improve their pedagogical skills related to NOS teaching. In Project ICAN, microteaching refers to a peer teaching presentation that mimics what teachers plan to do with their students. These lessons were planned and delivered by teams of teachers. A teacher team consisted of three to four members who were voluntarily changed for each peer teaching assignment. Each lesson was videotaped and afterwards there was a brief discussion of the aspects of NOS addressed as well as ways the lesson could be further improved.

In short, over the five years of the ICAN Project, peer microteaching experiences appeared to be an important professional development experience. These opportunities allowed teachers to become more familiar with teaching NOS and helped them reflect and develop their pedagogical content knowledge (PCK) related to NOS teaching. The development of teachers' pedagogical skills related to NOS teaching in Years 4 and 5 of the project was found to be consistent with students' improved understanding of NOS as revealed by analyses of student work. This result implies that TPD programs should provide teachers with opportunities to plan and implement explicit NOS instruction and to observe and discuss peers' microteaching lessons (Lederman, Lederman, Kim & Ko, 2006).

The present study argues that such opportunities to learn from peers could be more profound and effective if videotapes of NOS instruction in authentic classroom situations could be shared among the participants. This is because microteaching in front of peers cannot reflect a real classroom situation. To overcome this limitation, teachers participated in the present study have been asked to share and examine videotapes of themselves teaching NOS in authentic classroom situations.

Exploring dimensions of effective NOS instruction

Bartholomew, Osborne and Ratcliffe (2004) reported the work undertaken with a group of 11 teachers over a period of a year to teach aspects of the nature of science, its process, and its practices. The program consisted of development of curriculum materials, classroom trial run teaching and workshops. In this project, teachers were asked to develop curriculum materials in the beginning stage of the study. During the first three months of the study, four initial one-day meetings were held. These meetings provided participating teachers an opportunity to explore, plan, and develop materials for the explicit teaching of NOS. However, that had turned out to be a difficult task for teachers to design curriculum materials which explicitly address NOS elements. The researchers therefore drew from a range of existing sources (e.g. Goldsworthy, Watson, &Wood-Robinson, 2000; Ratcliffe, 1999) and worked out lesson outlines and some instructional materials. The researchers later modeled their conception of good practice for the effective teaching of NOS with the developed materials. Such models were offered as framework that teachers could try and adapt. The teachers would then work in age-specific groups to share, develop and adapt the modeled materials and approaches with their own ideas. Teachers then trial run the adapted materials and undertook lessons over a period of two terms. In brief, their findings suggest that effective teaching of NOS requires establishing a context in which it is possible for students to engage in reflexive epistemic dialogue. It requires teachers to shift in the conception of their own role from the dispenser of knowledge to facilitator of learning; a change in their classroom discourse to one which is more open and dialogic; a shift in their conception of the learning goals of science lessons from merely gain in subject knowledge to one which incorporates the development of reasoning and an understanding of the epistemic basis of belief in science; and the development of classroom activities which are owned by students and relevant to their daily life.

The five dimensions of effective NOS instruction suggested provide an initial framework for guiding the design of activities for the TPD program in the present study. They have also an important bearing on the design of the data collection instruments as well as the analysis of data at subsequent stages of the present study.

METHOD AND CONTEXT OF STUDY

This interpretive study on teacher learning is situated in a two-year-long TPD program. As informed by the previous studies illustrated above, there are three distinctive features in this program which aims at improving teacher's NOS knowledge and practice.

FEATURE 1: PROVISION OF CURRICULUM RESOURCES

The decision to provide teachers with curriculum materials for their trial runs has been informed by Bartholomew et al's study (2004) where they found teachers experiencing difficulties in designing their own curriculum materials. In this study, 17 sets of curriculum materials were developed for the explicit teaching of NOS across the biology curriculum. The design of the materials was guided by the notion of *educative* curriculum materials (Ball and Cohen, 1996; Davis and Krajcik, 2005). Teachers were invited to choose two sets of curriculum materials, to modify and to teach in their own classes.

FEATURE 2: MAKING USE OF VIDEO IN TEACHER LEARNING TO TEACH NOS

Other than informed by previous studies, the decision of using video in teacher learning is also supported by substantiate amount of relevant literature (e.g. Black & Atkin, 1996; Putnam & Borko 1997). For example, Sherin (2004) identifies several affordances that videos provide for teacher professional development - video as a lasting record; video can be collected and edited; video affords a different set of practices. In this study, videos of teachers teaching NOS in authentic classroom situations were used systematically to help teachers learning how to teach NOS. Specifically, the trial run lessons of teachers teaching NOS were videotaped. The video clips were then re-played and reviewed in the subsequent study group meetings for discussing the pedagogical issues involved.

FEATURE 3: ORGANIZATION OF STUDY GROUP

It appears that in all the three studies reviewed, peer learning did play a role in helping teachers learning how to teach NOS. In this study, teachers were provided with opportunities not only to learn from peers in form of study groups, but to decide on their own agenda for their professional development in learning how to teach NOS. For example, they were asked to select video episodes which they wanted to bring up for discussion in addition to those selected by the facilitators.

OVERALL DESIGN OF THE TPD PROGRAM

In brief, twelve biology teachers formed themselves into two study groups, each with six teachers and facilitated by a science educator. The teachers worked collaboratively in study group meetings to help each other to learn how to teach NOS. To start with, the teachers were given curriculum materials for teaching NOS using an explicit and reflective approach. They refined the resources and taught the modified curriculum materials in their own classrooms. The lesson videos were then shared and analyzed collaboratively in the study group meetings. Towards the end of the program, the two study groups will come together to share their experiences on themes of common interests in their learning of how to teach NOS. The major TPD activities were listed in table 1.

Table 1: Major activities in the TPD program

Major TPD activities	Descriptions
Briefing session	• Introduce the objectives and the professional support provided by the TPD program
Planning meeting	• Gather teachers in study groups and work for the learning agenda • Introduce strategies for teaching NOS • Initiate the process of refining curriculum resources by teachers
Two-day training workshops on teaching NOS	• Consolidate teachers' knowledge base on NOS the relevant pedagogical content knowledge (PCK) for the teaching of NOS • Content: common myths about NOS; planning a lesson on NOS; teaching NOS across a series of lessons; consolidating NOS learning; teaching NOS on unplanned occasions
Pre-trial run discussion	• discuss the lesson plan and the refined teaching materials with facilitator
Trial run	• try out refined package in own classroom
Post-trial run discussion	• Discuss the trial run lesson with other teachers and the facilitator
Study group meetings	• Review and analyze trial run lesson videos in the study group to look for ways of improvements
Thematic workshops (yet to be finished)	• Discuss and share exemplary video cases contributed by each of the study groups
Debriefing meeting (yet to be finished)	• Teachers will celebrate with their peers on their experience in learning to teach NOS. • Teachers will be invited to share and reflect on their learning to teach NOS through the entire TPD program.

For triangulation purposes, multiple data sources were employed in constructing the case of teacher learning reported below. These include: (1) Gloria's reflection tasks completed after two NOS lessons and the corresponding follow-up interviews; (2) her reflection tasks completed after reviewing two NOS lesson videos and the corresponding follow-up interviews; (3) her e-mails, telephone conversations and face-to-face discussions with TPD facilitator concerning planning and teaching of the two lessons; and the researchers' lesson observation and field notes.

FINDINGS

Gloria is an experienced teacher who has taught biology for more than 20 years. She is very enthusiastic in professionally upgrading herself. This is the second time for her to join a similar TPD program on preparing teachers for NOS teaching. This time, one of the key learning Gloria mentioned in her reflection tasks is the importance of leaving enough time for student's discussion. In this paper, the journey of how Gloria have come to grips with her important learning of "not to hurry things" in teaching NOS as well as how various factors in the TPD programs had contributed her learning will be discussed.

LEARNING FROM THE FIRST NOS LESSON: BARRY MARSHALL'S DISCOVERY OF THE CAUSE OF GASTRIC ULCER

1) Planning the lesson

One week prior to her teaching, Gloria sent the lesson plan and refined teaching materials to the TPD facilitator for comment and advice. She had planned to have 4 group discussions, students' poster presentations, whole class discussion, lecturing and playback of a 10-min video clip on a TV interview with Dr Barry Marshall. During the pre-lesson discussions, the

TPD facilitator advised her to trim some of the contents so as to leave enough time for the group discussions. Even though Gloria had agreed to trim down the contents, she failed to leave enough time for the student discussions during the lesson.

2) Reflecting on the lesson

When asked what were her learning and the difficulties in teaching this lesson, the first sentence Gloria wrote in her reflection task was:

> 'I should have left more time for class interaction and group discussion.'

She recalled in one of the group discussions (on the proposal of hypothesis), students had disagreement among themselves, but she did not put aside enough time in her lesson plan for the discussion:

> '⋯ if I have enough time, I would ask students to clarify what they think, or to give comments to other students' ideas…I realize that when I was planning the lesson, I did not think exhaustively enough. After the lesson, I understand that it would be better if there was a bit more time for discussion.'

In a follow-up interview, Gloria explained how she had come to aware of the problem. She pinpointed that the peer interaction with other teachers during the study group meeting had helped her to reflect on this learning.

> "I have been teaching for so many years…of course if somebody observe my lesson (other teachers and the TPD facilitator), they can remind me and tell me which part I can improve. Their opinions are more objective."

3) Reviewing the classroom video

In response to a question on the accompanying task sheet, 'Write down the new insights gained from reflecting on the lesson's video, Gloria put down:

> 'wait time is very important, not to hurry students'

In the follow-up interview, Gloria explained how she had benefited from reviewing her own lesson video.

> 'After I have watched the video, I try to remind myself one thing. Whenever I teach NOS, which requires high-order thinking, I should give more time for the students to think deeply. I do not want them to feel that they have to rush. Even if I say "You don't have to hurry", you are actually pushing them…Because I saw from my video that I did say "We have to be faster" during the class…'

LEARNING FROM THE SECOND NOS LESSON: THE FUNCTION OF NUCLEUS

1) Planning the lesson

Two months later, Gloria conducted another lesson with an explicit focus on NOS teaching. This time, Gloria did not follow the teaching plan suggested in the teaching package. Instead, she chose to spend time on discussing questions in the pre-lesson task that comes along with the teaching package. She planned to discuss 11 questions in a 90 minutes' lesson. The facilitator commented that there were too many questions and student might not have time to discuss all the questions thoroughly.

During a follow-up interview, Gloria acknowledged the support from the facilitator during the planning stage. She said the pre-lesson discussion had helped her to iron out the key questions to be discussed and reminded her how to better allocate the time for discussion.

> *"The facilitator did remind me to let students to work on the questions individually first before having the group discussion… Allotting 3 minutes for students to work on the questions individually is just too demanding for them. So, how to better allocate the time; how to decide which question to present in the limited lesson time are important."*

2) Reflecting on the lesson

Similar to her experience with the first NOS lesson, time management continued to be a main concern for Gloria as revealed in her reflection task of the second NOS lesson. Below are a few of the relevant excerpts:

> *'There were a lot of learning materials in my lesson plan so I needed to decide which part had to be cut.'*
>
> *'It was difficult to allocate the appropriate amount of time for students to work on the questions individually, and then to participate in group discussion and presentation'*
>
> *'Time control in group discussion is much more difficult than what I thought.'*

In the reflection task, Gloria also recalled how she managed not to rush students to finish the discussion in this second trial.

> *'I did not allocate enough time for the discussion. I was a bit hurry. The discussion was a bit overrun. But, finally I managed to let it go. I told myself that just give them more time to discuss… do not rush the lesson...'*

Overall, Gloria treasured the time discussing the questions with the students. In her reflection, she expressed at least *4 times* that she would rather increase rather than cut short the time for students' discussions, as she put it.

> *'I think the (eleven) questions are worth discussing, because students can have the opportunity to think, to discuss and to argue. If I were to conduct the lesson again, I would spend 3 lessons instead of 2 lessons.'*

In responding to the last question of the reflection task, 'Is there anything you would like to share about learning to teach NOS with others?' Gloria put down *'wait time'*.

3) Reviewing the classroom video

In reviewing her lesson video, Gloria highlighted several episodes where she was concerned about her time management for class discussion. For example:

> *'For the first group discussion on … , I should have left ample time for group discussion.'*
>
> *'(It is) good to allow students to think on their own before getting into group discussion, especially for questions which are more demanding. The "Think Time" is important'.*

In revisiting the whole learning experience of participating in this study, Gloria found that her personal belief about teaching, her experience of teaching these two NOS lessons, sharing with the peers and facilitator and the opportunity for her to review her own classroom videos contributed to her learning about the paramount importance of time management in discussion.

DISCUSSION

An explicit and reflective approach of teaching NOS has been advocated as an effective way of teaching NOS (e.g. Abd-El-Khalick & Akerson, 2004). In Gloria's case, she had planned for an explicit and reflective approach. She did provide students with a lot of opportunities to experience the kind of discussions that scientists normally undertake in scientific inquiry. However, insufficient time was allotted to the activities. This resulted in students not gaining sufficient experiences of which they could subsequently reflect on; and hence affecting the effectiveness of the lesson (as expressed by Gloria). In other words, Gloria had come to grips with the essence of what it means by a reflective approach. That is, 'leaving enough time for student's discussion' is a prerequisite for adopting a reflective approach in teaching NOS. Without enough time for discussion, students will not have an adequate experience to reflect on from which they can derive their NOS understanding.

Indeed, the importance of wait time for effective teaching in general has long been stressed in the research literature and is well encapsulated by Rowe's (1986) paper entitled Wait time: Slowing down may be a way of speeding up! In his review on math and science studies, Tobin (1987) also came to a conclusion that wait time appears to facilitate higher cognitive level learning by providing teachers and students with additional time to think. However, allow more time for student to discuss and have a long wait time is often 'easy said than done' (e.g. Jegede & Olajide, 1995). Gloria is a case in point. This seemingly trivial and simple learning did not come easy but after a lot of inputs from the peers and TPD facilitator at different stages of the TPD program including pre- and post-lesson discussions, review of lesson videos and study group meetings. Based on Gloria's case, we argue that previous TPD efforts might have underestimated the difficulties and effort required to make teachers realizing 'the importance of leaving enough time for student's discussion and have long wait time' for teaching in general and teaching of NOS in particular. We suspect that much greater efforts will be needed to help teachers improve their practices in this area.

The above findings also provide glimpses of how features of the TPD program had contributed to Gloria's learning. For example, the provision of NOS teaching material provides an initial picture of how an explicit & reflective approach of teaching NOS is like. When Gloria modified and adapted the curriculum materials, she was actually "learning" how an explicit and reflective approach of teaching NOS is. Besides, as noted by Gloria, the facilitator's on-site comments and peer's comments in study group meetings are important reminders to her teaching. Without these comments, Gloria may not be notified where she can make further improvement. She may not realize "wait time" is an important learning to her, even though she is a teacher with 20 years of teaching experience.

Learning is more meaningful when it is embedded in the practice (Liberman, 1986). The provision of the trial run practice serves as first-hand NOS teaching experience to Gloria. As shown in the findings and her reflection, she learned most in teaching the two NOS lessons. The second trial run experience indeed echoed and reinforced Gloria's learning in the first trial lesson.

One of the affordances of video is it capability of allowing fine-grain analysis of teaching (Sherin, 2004). Seeing one's practice in authentic situation will only be possible when having the video technology. We believe that learning to teach NOS will be facilitated by this kind of video analysis. As evident in Gloria's case, because of the opportunity of the detailed analysis of her video, she actually "saw" from her video where she urged student to move faster in discussion and she noticed where she can do much better.

In sum, we argue that an effective TPD program for helping teachers to learn how to teach NOS should consider the provision of the NOS teaching resources, opportunities for trial teaching in authentic classroom situations and discussion with peers and knowledgeable others, and above all, the opportunity to review own classroom videos.

ABSTRACT

The role of information communication technology (ICT) in education in whole and particularly in science education is very important topic. The growth is characteristic not only at university level but also at other levels of the education system. It is accepted that ICT makes the process of teaching/learning more effective and beneficial whereas the education system starts functioning faster. The implementation of new technologies in the educational process raises new possibilities for both teacher and learner, enhances education quality and makes the educational process more versatile.

Pilot research Student and Computer-Based Technologies was conducted in October – November, 2009. To collect the required data, an anonymous questionnaire was prepared. Research sample consisted of 211 respondents who were 1st year university students (freshmen). In the majority of cases, the students learn to use computer independently, whereas next comes help provided by friends and family members. It has been established that computer-based technologies are very rarely used during the lessons of other subjects. The respondents think that using computer-based technologies in the classroom during the lessons of sciences has the highest impact on cognitive abilities (knowledge acquisition, self-sufficient studies etc.).

Keywords: *general schools, computer-based technologies, pilot research, science education*.

INTRODUCTION

Recently, common interest in using computer-based technologies for the purpose of teaching/learning sciences has significantly increased at international level. Different types of research are carried out to reason the efficiency of the applied technologies, an impact on broadening knowledge etc. Various investigations are conducted in Lithuania. The report of the international Software and Information Industry Association of the year 2000 summarizes more than 3500 studies on applying ICT for educational purposes and presents conclusions indicating that the use of ICT in the educational process can improve teaching/learning as well as may have a positive impact on the final results, attitudes and communication with teachers and other students. On the other hand, applying only the latest training aids cannot guarantee better results of teaching/learning. ICT is an absolutely effective instrument for teaching sciences. For instance, the possibilities of multimedia create conditions for establishing ‘virtual school laboratories’ and doing different imitations (for example, complex natural phenomena, expensive and complicated instruments). Computer-based technologies are widely applied to find connections between real and virtual laboratories and can be incorporated into more and more involved educational technologies. In this case, the application of Augmented Reality Technologies in educational practice can be mentioned as one of the examples. The international project Augmented Reality in School Environments "ARiSE" (http://www.arise-project.org) has revealed interesting results. Research on pedagogical effectiveness has disclosed that these technologies can be an effective instrument for improving the quality of teaching in general (Lamanauskas, Pribeanu, Vilkonis, Balog, Iordache, Klangauskas, 2007). The later performed in-depth research on pedagogical evaluation has also demonstrated positive results (Lamanauskas, Bilbokaitė, 2009). On the other hand, the problem is a choice between virtual and real teaching/learning environment. Real experimentation, examination etc. is crucially important for learning sciences. The researchers notice that both children and adults are strongly motivated by experimenting, discovering and understanding things in their own way (Bilek, Krumina, 2008). Thus, the basic problem is the coordination of real experimentation in the classroom with the experiments conducted in the virtual environment. Chemistry is one of the examples showing that sciences are based on experiments. The examiners find that strong emphasis on ‘pure’ e-learning only cannot be the only choice as most frequently this is a combination of e-learning and face to face or mobile process (Cedere, Priksane, 2006; Lovatt, Finlayson, James, 2007).

Research plays a fundamental role despite the fact that regardless of a growing number of computers in comprehensive school, the immediate use of those in the process of teaching/learning is insufficient due to different reasons. The teacher should be able to take into account and involve in their daily work rapidly changing technologies and new approaches and standards in the education field, which requires a higher performance both for students and teachers (Dudareva, Bruneniece, 2008). Teaching and learning are mainly based on the interaction between a teacher and a student. The before mentioned interaction is also determined by the use of computer-based technologies. Therefore, an important point is constant supervision and evaluation of using these technologies. The received information can help with identifying the existing shortcomings and finding adequate decisions on overcoming the encountered weaknesses which is relevant in terms of managing the educational process. First of all, this is due to the fact that arranging a lesson in the classroom and the methods of teaching/learning using computer hardware differ from that based on a traditional approach. Differently, the carried out sociological research on expanding the use of IT in Lithuanian schools shows that a position on applying IT in the educational establishments is rather limited and a wider application of computers usually ends outside informatics classroom (Bedulskis, 2005). Hence**, the object of research** is the use of computer-based technologies in the process of teaching/learning sciences. **Research is aimed** at establishing the positions of 1st year students on applying computer-based technologies in comprehensive school learning sciences and at disclosing the frequency of using these technologies in the classroom during the lessons on sciences.

RESEARCH METHODOLOGY

General Characteristics of Research

Pilot research *Student and Computer-Based Technologies* was conducted in October – November, 2009. A questionnaire was used as a method of the conducted study that fully corresponds to the Lithuanian context as the respondents were the graduates from different comprehensive schools throughout Lithuania.

The Applied Instrument

To collect the required data, an anonymous questionnaire including four main blocks was prepared.

1. The level of ability to use computer (in total, 30 parameters were included, for example, ability to use programs and documents, ability to operate fail search system etc.).
2. The methods of using computers (5 parameters were included, for example, learned during informatics classes; during classes in other subjects; during extracurricular activities; helped family members, friends etc.; individual learning).
3. The evaluation of the frequency of applying computer-based technologies during the classes of sciences (5 parameters were included, for example, the frequency of using a computer projector by the teacher; the frequency of demonstrations done by the teacher, the frequency of applying computer-based technologies by the students for the purpose of practical experimentation; the frequency of communication between students and teachers outside the classroom etc.).
4. Opinions on applying computer-based technologies during the classes of sciences at school. 20 closed type questions were addressed, for example, using computer-based technologies to make lessons more interesting, to increase motivation, for communication purposes etc.

All four blocks were made of closed type statements, the questions to which are given applying a ranking scale from 1 to 5. Every statement was given the calculated popularity/ability index ($0 \leq PI/AI \leq 1$). The closer is PI value to 1, the more important is the statement to the respondent.

The questionnaire also included a demographical part and some other additional variables (for example, the time the respondent uses computer; the daily average of time the respondent spends on learning using computer-based technologies).

Research sample

Research sample consisted of 211 respondents who were 1st year students.

Table 1. Characteristics of the surveyed respondents (N/%)

Sex	Female	Male	Total
	66/31.3	145/68.7	211/100
Locality	Graduates from city schools	Graduates from regional schools	Total
	95/45.0	116/55.0	211/100
Program of studies	Social sciences	Physical biomedical sciences	Total
	109/51.6	102/48.4	211/100

The field of social sciences was represented by the students of educology, economics, business administration and management. The field of physical and biomedical sciences involved the students of physics, optometry, mathematics, informatics, biology and ecology.

The sample of research consisted of students from four departments of the same university. Though it is not a random sample, however, it is supposed to be reliable due to the precondition that the respondents represent comprehensive schools located at different parts of Lithuania and that the major part of the surveyed participants graduated from these schools in 2009. In fact the choice of the university by students was partly random. From this point of view, the respondents' opinion on using computer-based technologies for the purposes of teaching/learning sciences in comprehensive school is accepted as very important and objective.

Statistical data analysis

To analyze research data, the measures of descriptive statistics (averages, popularity/ability indexes, standard deviations) and the method of data reduction (factor analysis) – multidimensional statistical analysis have been applied. To test equality of means, Independent Samples Test – t-test for Equality of Means has been applied. For comparison of a few independent samples, Factor Dispersal Analysis (ANOVA) (One –Way Anova) has been applied. The SSPS statistics batch is used as an instrument for data processing.

RESEARCH RESULTS

The ability of respondents to use information technologies

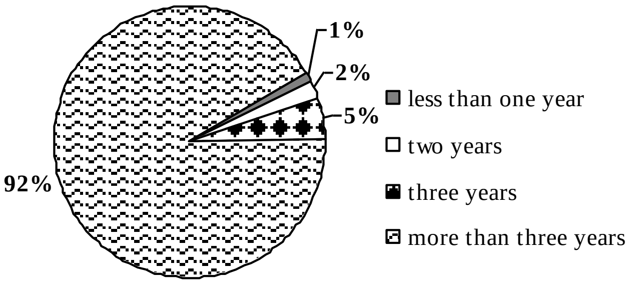

Figure 1. Duration of using the computer

The great majority of respondents (195/92.4 %) have been using computer for more than three years, nearly 1 %- for less than one year and over 6 %- for two or three years (Figure 1). Thus, the youth starting their studies at university have adequate experience and excellent opportunities for using computer technologies.

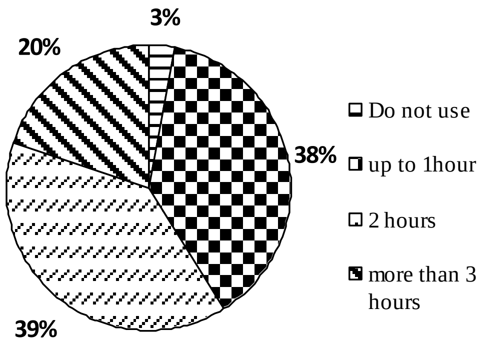

Figure 2. Duration (time) of using the computer for learning

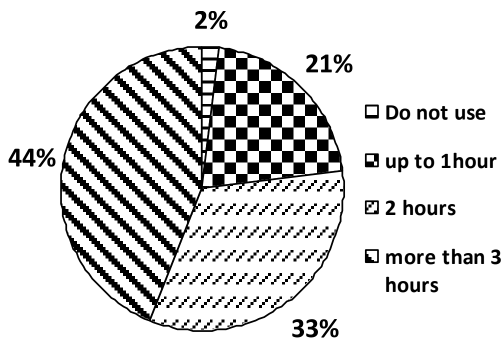

Figure 3. Leisure time at the computer

For learning 82/38.9 % I-st year SU students allot 2 hours, 81/38.4 %- up to 1hour and 42/19.9 %- more than 3 hours (Figure 2). 6 respondents (2.8 %) do not use computer while learning. We can assert, that modern computer technologies are actively used in teaching/learning process and computer itself is also a motivating means of learning. If students really allot 2 or 3 hours for learning every day it is likely that they will master subjects well and they will be ready for further career.

However, respondents allot even more time at the computer for leisure. 91/43.1 % of respondents spend more than 3 hours, 70/33.2 % allot 2 hours for this, 45/21.3 % -1 hour and only 5/2.4 % do not spend their leisure time at the computer at all (Figure 3).

Having analysed students' answers on computer literacy, it has been stated, that after graduation from comprehensive schools students possess quite good computer skills. They are able to change the font size, colour and style (AI = 0.93, SD = 0.14); to conduct the commands of coppying, cutting, deleting *(copy/paste, cut/ paste, delete)* (AI = 0.93, SD = 0.15), *to operate programme windows: to open them, to minimize, to close, to stretch* (AI = 0.92, SD = 0.16) and other. However, they lack specific knowledge for conducting more complicated operations, such as: bitmap and vector graphic software *(MS Paints, Adobe Photoshop, GIMP, CorelDraw, Adobellustrator* (AI = 0.43, SD = 0.26), *to create websites, to use website creation programmes (MsFrontpage, Macromedia Dreamweavery)* (AI = 0.25, SD = 0.26).

Seeking to decrease the number of variables without loosing the essential information, factor analysis employing the method of the main components with Varimax rotation has been carried out on 30 statements. 30 answers to one question were grouped considering six factors (Table 2). Taking into account general features these factors were named as follows: *More complicated functions of operating systems* (8 statements), *Basic operating systems and technical functions* (8 statements), *Special editing functions* (4 statements), *Work with files and computer equipment* (5 statements), *Elementary editing functions* (3 statements), *Internet, e-mail* (2 statements).

Table 2. The results of factor analysis of the ability of using computer and computer – based software

	FACTOR 1 *More complicated operating system functions*	**Factor loadings**	**Ability index (AI)**	
			Statement	**Factor**
1.	Make changes in programme settings	0.80	0.53	0.53
2.	Create websites, use website creation programmes (MsFrontpage, Macromedia Dreamweavery)	0.74	0.25	
3.	Install computer equipment drivers	0.72	0.56	
4.	Use file archiving programmes	0.72	0.54	
5.	Change systemic operating system parameters (sound, view, regional, keyboard language, computer clock)	0.69	0.69	
6.	Install programmes	0.68	0.66	
7.	Use bitmap and vector graphic software (MS Paints, Adobe Photoshop, GIMP, CorelDraw, Adobellustrator)	0.65	0.43	
8.	Know the main computer terms:bit, byte, megabyte, RAM, ROM, BIOS, HTTP, FTP, IP, RGB	0.62	0.60	
	FACTOR 2 *Basic operating systems and technical functions*	**Factor loadings**	**Statement**	**Factor**
1.	Operate programme windows: open them, minimize, close, stretch	0.70	0.91	0.87
2.	Use the main Windows OS graphic environment elements: desktop, browser (Windows Explorer), recycle bin, start button, taskbar.	0.68	0.87	
3.	Use mouse context menu	0.62	0.83	
4.	Use data storage equipment: compact discs (CD-ROM), usb stick (insert, remove, set and record data, formate)	0.62	0.87	
5.	Start programmes and documents	0.60	0.91	
6.	Correctly turn on and turn off the computer	0.59	0.95	
7.	Use computer input equipment (all letter number and function keys	0.51	0.88	
8.	Find files and folders in the hierarchic folder system	0.48	0.75	
	FACTOR 3 *Special editing functions*	**Factor loadings**	**Statement**	**Factor**
1.	Change the format of the paragraph: text alignment, line spacing, indentation, borders, background colour	0.74	0.79	0.77
2.	Change the printing page setup	0.72	0.76	
3.	Insert tables, number the lists,pictures and other more complicated objects	0.70	0.77	
4.	Check the spelling	0.68	0.75	
	FACTOR 4 *Work with the files and computer equipment*	**Factor loadings**	**Statement**	**Factor**
1.	Connect by wires the main external equipment with computer central processing unit: monitor, keyboard,mouse, speakers, microphone, printer	0.76	0.80	0.76
2.	Use file search system	0.62	0.79	
3.	Recognize the main file formats: exe, doc, txt, html, gif, jpg, mpg, mp3, zip, rar	0.59	0.75	
4.	Use Help system	0.54	0.65	
5.	Create file shortcut	0.51	0.80	
	FACTOR 5 *Elementary editing functions*	**Factor loadings**	**Statement**	**Factor**
1.	Conduct text copying and cutting,deleting commands (copy/paste, cut/ paste, delete)	0.77	0.92	0.92
2.	Change font size , colour and style	0.74	0.93	
3.	Conduct the main functions with files and folders: create, delete, copy, move, rename	0.74	0.91	

	FACTOR 6 ***Internet, e-mail***	Factor loadings	Statement	Factor
1.	Use the main internet browser functions: open the required page, download the files, find reviewed pages and so on.	0.71	0.85	0.87
2.	Use the main e-mail functions: read the received e-mail,create a new mail, send, forward, reply to the sender and so on.	0.62	0.88	

Ability index was calculated for every factor (AI). The obtained result shows, that the fifth factor has the strongest expression (AI = 0.92). Respondents are able to conduct elementary editing functions, such as: copy, paste, delete, change the font size, style and other the best. They also successfully use contemporary knowledge gathering and communication tools, such as internet and e-mail (AI = 0.87). Students are familiar with basic operating systems and technical functions (factor 2, AI = 0.87). The majority can operate programme windows (*open them, minimize, close, stretch*), use data storage equipment: compact discs (CD-ROM), usb stick (*insert, remove, set, record data, formate*), use computer input equipment (all letter, number and function keys) an so on.

The first factor- *More complicated operating system functions* (AI = 0.53) has the weakest expression. It is not easy to learn independently to create websites, change programme settings or install them. This can be learnt at school during informatics lessons, however they are not compulsory for senior class students.

Because of the fact that majority of students spend about 5 hours on avarage at the computer, the question arises whether the ability to use computer and computer software depends on the time spent at it. The carried out statistical analysis showed that computer knowledge and abilities do not depend upon the average of time spent daily at the computer for learning. However, a statistically significant deviation between time spent at the computer for leisure and the ability to use computer and computer programmes has been obtained. Those respondents who spend more than 3hours of their leisure time at the computer (AI = 0.63) are able to use More complicated operating system functions better (Factor 1), comparing to those who spend 2 and less hours (AI = 0.45). The null hypothesis about equal averages is rejected at the level of significance and makes $p < 0,0001$ ($F = 10.269$, $df = 3$). Students, spending more their leisure time at the computer, work better with files and computer equipment (AI = 0.85 compared with AI = 0.66, $p < 0.0001$, $F = 12.726$, $df = 3$); Factor 4). There is no statistically significant variation on other factors. We can think that students could learn independently things they were not taught at school, that leisure time at the computer is not only games but improvement as well.

Having carried out analysis in terms of schools, no significant deviations have been noticed.This shows that there are equal opportunities for regional students and for students from the city to acquire the basic knowledge of computer literacy.

A statistically significant deviation in terms of sexes has been obtained on the first, second and fourth factors. The null hypothesis H_0 about equal averages is rejected at the level of significance and makes $p < 0.001$.

Male students can operate more complicated operating system functions(AI = 0.72) significantly better ($t = -9.244$, $df = 209$), than female students (AI = 0.45). Male students can also use basic operating systems and technical functions better than female students (male students AI = 0.92, female students AI = 0.85; t = -3.551, df = 209). Male students succeed in working with files and computer equipment better (AI = 0.86), than female students (AI = 0.70; t = -6.260, df = 209). Other computer literacy knowledge (factors 3, 5 and 6) both of male students and female students is the same. (statistically no significant deviation has been noticed).

Analyzing the answers of the respondents distributed according to specialities: social sciences (SO) and physical, biomedical sciences (FB), statistically significant deviation on the first and on the fourth factor has been obtained. The null hypothesis about equal averages is rejected at the level of significance and makes $p < 0.001$. FB speciality students (AI = 0.61) are able to use more complicated operating systems better (t = -4.246, df = 209), than SO students (AI = 0.46). Also, FB students work better with files and computer equipment (FB students AI = 0.82, SO students AI = 0.70; t = -3.851, df = 209). Such result has been expected because among FB students there is a part of students,having chosen to study informatics and other specialities where deep knowledge of informatics is necessary.

Respondents ’computer literacy acquiring ways

The respondents‘ knowledge of using computer was assessed. The obtained results are presented in Table 3. The popularity index ($0 \le PI \le 1$) and standard deviation were calculated.

Table 3 shows that individual knowledge (PI = 0.84, standard deviation SD = 0.21) as well as friends, family members etc. (PI = 0. 72, SD = 0. 27) most frequently helped the students with using computer. A part of students found important knowledge and skills gained during informatics lessons (PI = 0. 63, SD = 0. 28). However, only a minor part of the respondents improved their knowledge and skills during the lessons of other subjects and extracurricular activities.

Table 3. Gained knowledge of using computer

	Ways of learning	N	PI	SD
1.	Independently	211	0.84	0.21
2.	Helped friends, family members etc.	211	0.72	0.27
3.	During informatics lessons	211	0.63	0.28
4.	During the lessons of other subjects	211	0.40	0.26
5.	During extracurricular activities	211	0.39	0.29

Forming two groups of respondents considering their specialities revealed (social sciences (SS) and physical/biomedical sciences (FBS) that taking into account all 5 parameters, no statistical significant deviation between the opinions of the students representing these groups was noticed.

A statistically significant deviation between the opinions of the graduates from city and regional centre schools was established in view of the impact of informatics lessons on improving knowledge about using computer. The null hypothesis about equal averages is rejected considering the level of significance which is $p < 0.001$. Informatics lessons had a higher impact on knowledge (t = -4.655, df = 209) of the students from regional centres (PI = 0.70) rather than on those from the city (PI = 0.53).

An assessment in terms of the sex indicates that female students learn better during informatics lessons than male students (t = -4.020, df = 209), respectively (PI = 0.68) and (PI = 0.51). Female rather than male students were also stronger influenced by other people (t = -3.736, df = 209), respectively (PI =0.77) and (PI =0.62). The null hypothesis about equal averages is rejected and the level of significance is $p < 0.001$. Though both male and female students in the majority of cases learnt to use computer independently, however, female students seem to be more straightforward and receptive to informatics lessons and help from other people.

Using computer-based technologies during the lessons of natural sciences

An assessment of the frequency of applying computer-based technologies during the classes of sciences (physics, biology, chemistry, geography) disclosed they had been used very rarely. The teachers relatively frequently used computer presenting new material during physics (PI = 0.30) and biology (PI = 0.23) lessons. Also interactive demonstrations were organized during physics (PI = 0.31) and biology (PI = 0.22) lessons. At times, the students self-sufficiently did homework and tasks on biology (PI = 0. 23) and physics (PI = 0. 20). Computer-based technologies were hardly applied during chemistry and geography lessons. It should be noticed that the teachers of sciences have a contact with students very rarely outside the classroom, i.e. give advice and prepare different tasks using appropriate software. No statistical deviation has been established between the answers of male and female students from the city and regional centre about the frequency of using computer-based technologies in the classroom.

Respondents' opinion about using computer-based technologies at school learning natural sciences

An assessment of opinions on applying computer-based technologies during the classes of sciences at school and the impact of computer-based technologies on personal development has been undertaken. The following statements can be regarded as the most relevant: *Using appropriate software made the process of learning more interesting during lessons* (PI = 0.79); *Computer-based technologies used by teachers made the lesson more engaging* (PI = 0.76).

However, the respondents have doubts about: *Using computer-based technologies in the classroom for the purpose of raising individual motivation* (PI = 0,50); *Using computer-based technologies in the classroom for the purpose of raising interest in sciences* (PI = 0, 47).

It is supposed that the respondents do not relate computer-based technologies to learning motivation and deeper interest in sciences as in comparison the teachers of sciences rarely apply computer-based technologies in the process of teaching. However, sciences in particular open up strong possibilities of using these technologies for educational purposes.

Factor analysis was carried out employing the method of the main components with Varimax rotation. 20 answers to this question were grouped considering three factors (Table 4). 6-7 statements describe each statement. Taking into account general features these factors were given the names *Interchangeable abilities, Negative impact of computer-based technologies* and *Cognitive abilities*.

Table 4. The results of factor analysis of using computer-based technologies

	FACTOR 1: *Interchangeable abilities*	**Factor loadings of items**
1.	Using software generated interest in the latest technologies	0.74
2.	Using computer-based technologies helped with choosing an individual method of learning.	0.74
3.	Using computer-based technologies in the classroom promoted communication between students	0.72
4.	Using computer-based technologies increased interest in sciences	0.65
5.	Using computer-based technologies helped with many-sided development of skills	0.64
6.	Using computer-based technologies helped with applying available knowledge in practice	0.64
7.	Using computer-based technologies in the classroom increased personal motivation for learning	0.63
	FACTOR 2: Negative impact of computer-based technologies	
1.	Using computer-based technologies distracted attention, prevented from intense concentration	0.80
2.	Using computer-based technologies prevented from continuous learning	0.78
3.	Using computer-based technologies in the classroom used to provoke stressful situations	0.73
4.	Using computer-based technologies has a negative impact on health	0.70
5.	Applying computer-based technologies in the classroom used to cause problems of communication with the teachers of sciences	0.68
6.	Using computer-based technologies in the classroom only increased dependence on them	0.67
7.	Using computer-based technologies has no impact on the process of learning	0.49
	FACTOR 3: *Cognitive abilities*	
1.	Computer-based technologies created possibilities of a better understanding of a new topic	0.77
2.	The applied software helped with a better acquisition of knowledge	0.77
3.	Lessons used to be more interesting when using computer-based technologies in the classroom	0.66
4.	Computer-based technologies created conditions of independent learning	0.65
5.	Lessons were not so tiring using computer-based technologies	0.63
6.	Using computer-based technologies in the classroom added more variety to the process of learning	0.62

The first factor *Interchangeable abilities* covered 7 statements describing the impact of IT on interest in sciences, technologies, motivation for learning, practical use as well as communication and collaboration between students. The second factor *Negative impact of computer-based technologies* embraced another 7 statements characterizing the impact of IT on concentration, consistent studying, stress removing etc. The third factor *Cognitive abilities* consists of 6 statements giving an account the impact of IT on learning a new topic, acquiring knowledge and making the process of learning more interesting. Every factor was given the popularity index (PI) (Table 5).

Table 5. The popularity indexes of factors

	N	PI	SD
Factor 1	211	0.57	0.18
Factor 2	211	0.31	0.17
Factor 3	211	0.71	0.15

Table 5 shows that the third factor has the strongest impact (PI = 0.71). The respondents accept that computer-based technologies have the highest impact on cognitive abilities, i.e. using computer helps with increasing the quality of learning. The obtained result PI = 0.31 of the second factor indicates that using IT in the classroom helps with concentration, prevents form distracting attention and does not create stressful situations, i.e. has no negative impact on the state of health and personal development. In terms of the first factor, slightly positive attitude exists (PI = 0.57). The respondents do not overemphasize the impact of computer-based technologies on motivation for learning, practical use as well as on communication and collaboration between students. A statistically significant deviation between the opinions of the respondents from the city and regional centre and the impact of computer-based technologies on the first factor *Interchangeable abilities* has been noticed. The null hypothesis about equal averages is rejected at the level of significance and makes $p < 0.001$. In terms of this aspect, the position of the surveyed participants from regional centres (PI = 0.60) is more positive ($t = -3.425$, $df = 209$) rather than of those from the city and makes (PI = 0.52). Therefore, it is supposed that the respondents from regional centres still want to use computer-based technologies more frequently than those from the city and therefore are more active in communicating and collaborating with their colleagues or are more engaged in sciences when using computer-based technologies.

Considering the opinions of the examined respondents in all factors, no statistical deviations between male and female students as well as between social and physical, biomedical sciences have been noticed.

DISCUSSION

It is without doubt, that modern computer technologies are actively used in teaching /learning process both in comprehensive and higher school. However, the question of their effective usage remains. It is also important that natural sciences require especially good quality visualization. Many schoolbooks, physical models and posters are outdated and no longer suitable for use, they do not display 3D or interactive objects (Bilbokaitė, 2009). On the other hand, students like working with computers, e.g., carry out different tasks, model things and so on. It is obvious that in natural science education the computer programmes are often used for modelling processes which cannot be demonstrated in real lessons (Myška, Kolar, Bilek, 2009). Moreover, various innovative teaching/learning platforms are being created, the applying of which in real educational practice will require appropriate computer literacy abilities from all education participants. As an example we can mention an Augmented Reality teaching /learning platform as an innovative technology aimed at implementing links between the real and virtual world. The technology developed by the

ARiSE project focuses on offering conditions for customers not only to observe a combined view (real and virtual) but also to directly interact with the real world (real objects) (Lamanauskas, Bilbokaite, 2009).

Therefore, technologies should not alienate from human being and reality. We should devote all our efforts to stimulating youth interest in science and technologies and to reinforcing scientific-technological education at all levels. Although hardly anyone suspects that technologies are having a growing impact on our daily life, however, they still remain alienated from the major part of society members and policy makers and what is more, frequently stand outside the door of the education system. We should discuss and try to solve all key problems really using the ICT in everyday school (and universities) activities (Lamanauskas, 2009). Our research showed that our I-st year students, virtually, are able to use computer technologies. They acquire these abilities not only at school, but from different other sources. Quite a big part of students can work with operating systems, which is, in fact, the function of a higher school. From this point of view, it is important to constantly observe the abilities of the youth coming to universities to use computer-based technologies and adequately renew study programs. E.g., the research showed that physical and biomedical science students are able to use computer-based technologies better than the students of social and humanitarian sciences. Undoubtedly, better preparation of Lithuanian comprehensive school teachers to use technologies in the teaching process has influence on this as well. For example, in 2006/2007 only 49 % of teachers were using ICT for teaching their subject. In 2008/2009 their part increased up to 67 % (Masaitis, 2009).

On the other hand, we have different students at school and at universities too. Their capabilities are so different. This means that modern teaching and learning combines different approaches. It is called “blended learning”. We also have to analyse the employment of different other technologies in the studying process. It is clear that little empirical reseach has been published on students` general use of technology in the context of Lithuanian higher education. The youth coming to universities use rather different technologies, e.g., computers, internet, mobile phones, e-mail and other. Hopefully, the more detailed and profound research will disclose up to now unnoticed things, which are very important in organizing the studying process. The research carried out in Australia showed that many first year students are highly tech-savy, however, when one moves beyond entrenched technologies and tools, the patterns of Access and use of a range of other technologies show considerable variation (Kennedy, Judd, Churchward, Krause, 2008). The authors hope that the more exhaustive research, started on the basis of this research, will help to uncover how students use in their studying process hardware and the Internet, computer based technologies, mobile phone based technologies, technology based tools, and web based technologies.

CONCLUSIONS

The results of the carried out research *Student and Computer-Based Technologies* has shown that:

- Computer knowlwdge and abilities do not depend on how much time on average daily computer is used for learning however, students spending more than three hours at the computer are able to conduct more complicated operating system functions and use more diverse programmes.
- It has been stated, that students are the best at conducting elementary editing functions,using internet and e-mail as a means of knowledge search and communication, operating programme windows,using data storage equipment, using computer input equipment and so on. The weakest point is creating websites, changing programme settings or installing them.
- It has been stated, that male students can use more complicated operating system functions significantly better than female students. Male students also succeed in using basic operating system and technical functions and working with files and computer equipment better than female students.
- In the majority of cases, the students learn to use computer independently, whereas next comes help provided by friends and family members. The lessons of informatics have a higher impact on the learners from regional centres and female students. The classes on other subjects and extracurricular activities have no significant impact on increasing knowledge of work at computer.
- It has been established that computer-based technologies are very rarely used during the lessons of other subjects. The teachers relatively frequently used computer during the lessons of physics and biology, les frequently - during the classes of chemistry and physics. The teachers of sciences very rarely use computer-based technologies outside the classroom, i.e. for tutoring, giving advice, performing different tasks.
- The respondents think that using computer-based technologies in the classroom during the lessons of sciences has the highest impact on cognitive abilities (knowledge acquisition, self-sufficient studies etc.). However, they do not find important the impact of technologies on motivation for learning, practical use, communication and collaboration between students. Moreover, applying computer-based technologies in the classroom helps with concentration, prevents from distracting attention and does not lead to stressful situations, i.e. has no negative impact on the state of health and personal development.

All these conclusions cannot be applied to the whole population, nevertheless they clearly show the general tendencies. Researchers can use the presented results for designing of more representative research.

ABSTRACT

Since adopting usable ICT tools to be used in science teaching and learning is still a challenge for teachers, there is a need to support teachers and enhance their potential regarding this matter. The prototype of an in-service teacher education course aimed at helping European science teachers to adopt usable ICT tools in their classrooms has been designed. In this paper, we discuss the problem analysis behind the design. In accordance with design-based research procedure, the first step was the theoretical analysis of the usability of ICT tools. Secondly, an international survey was conducted in order to clarify the needs and constraints of using ICT tools in science. Based on the survey, not only technical but also pedagogical usability should be introduced and discussed with the teachers during the course. Lastly, we discuss the course design from the perspective of problem analysis and the attempt to address the needs regarding ICT tools in science education.

Keywords: *ICT, usability, teacher education, design-based research*

INTRODUCTION

OECD (2006) has pointed out the increasing gap between the current use of Information and Communication Technology (ICT) for teaching and learning in schools and the daily experiences that pupils have with technologies outside of school. On the other hand, governments and other stakeholders in OECD countries have dedicated large budgets to ICT projects in schools. In science education several paradoxes can be recognised in the research literature considering the use of Information and Communication Technology (ICT) in science education (e.g. OECD, 2004; 2006; Lavonen, Lattu, Juuti, & Meisalo, 2006; Younie, 2006; Hayes, 2007; Hennessy et al., 2007):

- national level ICT-strategies, and national curriculum guidelines for ICT use have been prepared during the last two decades in several countries, but the influence on the visions and practice of the teachers regarding the use of ICT in education seems to be remote;
- there is research evidence of the influence that using ICT has on students' learning process and motivation, but teachers do not rely much on research-based evidence to identify good practices;
- students have rich experience in using technology outside the school context but not using technology for learning in school;
- science teachers are rather skilful in using technology, even if they are unable to make good use of their competence through applying ICT tools in their teaching;
- ICT is available at school, but science teachers' beliefs about teaching and learning, e.g., beliefs about good practice in school, do not support educational use of technology;
- plenty of teaching and learning material especially with a focus on using ICT in science education already exists (Osborne & Hennessy, 2003). However, science teachers are not experienced in using these materials effectively within regular classroom activities.

In general, there is a broad agreement about the reasons why ICT should be integrated into science education and the advantages of its use in teaching and learning science. The field of technology in education is seen to be important on the grounds of numerous specific web-pages[15] and associations for supporting use of ICT in science education. Despite active promotion of ICT use in education as part of educational policy and reform in science education, it is well known that change is either very slow or tends to fail. Implementation is a complex procedure, and it needs more than just a direct government policy to put it into practice (Younie, 2006; Lavonen, Juuti, Aksela & Meisalo, 2006). Consequently, it is a challenge to support science teachers in adopting the use of ICT as a part of their teaching in the classroom.

The project, Effective Use of Computer Aided Teaching and Learning in Science Education was launched together with six European countries in 2008. The aim is to design and to test various parts of an in-service teacher education course focusing on the adoption of versatile use of ICT in science education. In this paper, we focus on a particular course module concerning the issues related to choosing usable ICT tools for science teaching. However, because of the various educational traditions and teaching practices in different countries, designing a course to address the needs of European science teachers is as much a challenge as it is an enriching experience. The aim of this paper is to describe the theoretical and empirical problem analysis needed for designing the course, and thereafter, to discuss how these needs are to be taken into consideration in the course design.

DESIGN-BASED RESEARCH APPROACH FOR THE COURSE DESIGN

As a methodological framework for designing the teacher education course, we use the design-based research approach (DBR) that has been suggested as a solution for the discontinuation between educational research and praxis (Juuti & Lavonen, 2006). It is a general framework for design, development, implementation and evaluation of learning activities and it uses a pragmatic frame. DBR emphasises three aspects: (a) a design process is essentially iterative starting from the recognition of the need to change praxis, (b) it generates a widely usable artefact, like learning activities or a learning environment, (c) and it provides educational knowledge for more intelligible praxis (Design-Based Research Collective, 2003; Bell, Hoadley, & Linn, 2004).

15 http://www.york.ac.uk/org/seg/about_us/pages/ict_download_page.htm (The University of York Science Education Group) http://ict-in-science-education.wikispaces.com/ (Information Communication Technologies in Science Education)

DBR is comprised of the combination of theory development, the prescriptions of successful design processes, and the prescriptions of successful design solutions. The design procedure contains four main phases: 1) needs assessment; 2) theoretical problem analysis and definition of the objectives for a design solution, artefact; 3) design and production of the artefact; and 4) evaluation of the artefact.

OUTLINING THE POINT OF DEPARTURE FOR THE COURSE DESIGN

In this paper, we concentrate on describing the first two phases of the DBR procedure concerning needs assessment and theoretical perspective regarding ICT use in science education. The theoretical analysis illuminates existing challenges in the field in general, whereas the needs assessment focuses on what would be useful and needed from the point of view of the teachers representing especially six participating countries in the project.

THEORETICAL PROBLEM ANALYSIS

Theoretical problem analysis starts with a short description of the different ways of using ICT in science teaching and learning. Secondly, we will take a look at an adoption process of ICT use in science education. After the general review, we continue with a special focus on the aspects regarding the usability and versatile use of ICT tools in science learning activities. We have divided our review into two categories, technical and pedagogical usability, in order to clarify the knowledge of this complex and multifaceted area so as to be more applicable for our purposes.

The concept *ICT use in science education* is considered here as an innovation to be adopted by science teachers. We categorise ICT use here into *(A) tool applications or tool software* and *(B) ICT use in study and learning (learning through ICT)* (cf. Webb, 2002). In the *tool category (A)*, ICT is treated as a set of available software enabling students and teachers to accomplish their tasks in a more efficient way. Typical examples of tool software are related to school, course administration, or office software (text processing, spreadsheets, graphics, etc.).

Science teachers can use tool application in several ways. In addition to the previously mentioned, teachers can prepare assignments, tests, and other resources for teaching and learning. An LCD projector can be used as a tool for presentations in several ways and connected for example to a microscope. Furthermore, beside the rather traditional way of using ICT, an *interactive whiteboard* (White board, SMART Board) provides a new perspective for teaching and learning when promoting interaction and cooperative activities as well as dynamic use of ICT in the classroom. The touch-sensitive display connects the computer and digital projector, and therefore, computer applications can be controlled directly from the display, notes can be made with digital ink and the work can be saved and shared later on.

The main uses of *ICT in science studies and learning (B)* can be divided into three categories regarding direct support for learning: (i) Computer-assisted learning (CAL) is any interaction between a student and a computer system designed to help the student to learn. CAL includes, for example, simulations (Applets in the Internet) and virtual-reality environments; (ii) Computer-assisted research is the use of ICT as an aid in collecting information and data from various information sources with the emphasis on the use of ICT in supporting scientific reasoning. Typically, these investigative activities are conducted in small collaborative groups where ICT is used as an agent for interaction with the information source, like the Internet or nature through Microcomputer-Based Laboratories (MBL); (iii) Computer-assisted interaction: Open and distance learning (ODL) has evolved in a natural way from using only regular mail to using all available IT services adjusted to fully facilitate student learning. Thus, modern ODL solutions are based on a wide range of communication technologies, such as course management systems, for example Moodle, and two-way audio/video tele-conferencing. Nowadays, schools are more involved with ICT-based interaction channels. The Web 2.0 ideology is increasingly implemented for example through wiki and blog activities.

However, it is known that there are constraints: ICT use might be too complicated for beginners, science teachers do not easily collaborate with each other or with experts, they feel that they do not have enough time for experimenting, they might have negative attitudes towards innovations and the lack of motivation to adopt them, support available is not sufficient and, furthermore, people are doubtful about new ideas and innovations. Variables that influence the uses of ICT in science education are consistent with other research findings regarding innovations and diffusion or adaptation of innovations. The diffusion is a process by which the versatile uses of ICT in science education are communicated over a time period among the science teachers (social system) (cf. Rogers 2003). Rogers differentiates the adoption process from the diffusion process and defines the former as an individual's mental process through which he or she passes from first hearing about an innovation to final adoption. The adoption process can be divided into several stages, for example, as follows: awareness, interest, evaluation, trial, and adoption. Individuals who are members of the society adopting the innovation can be categorised into adopter categories: innovators, early adopters, early majority, late majority, and laggards (Rogers, 2003).

Fullan (2001) categorises the properties of educational innovations that affect their adoption in two general classes: Firstly, there are the properties of the innovation; in this case, the properties of the 'ICT use in science education' itself (e.g., different ways ICT use is practiced in TE, usability of ICT, and easiness of ICT use). However, the nature of this innovation is not simple. For example Watson (2001) argued that its adoption requires change in teaching style, change in learning approaches, and change in access of information. Secondly, Fullan (2001) emphasises that there are local characteristics, such as the pedagogical orientation of the science teachers, nature of collaboration and reflection between teachers, their beliefs about the usability of educational technology, administrative leadership, technical and pedagogical support available, and external factors such as funding, nature of training or staff development, as well as the nature of development projects in ICT use. Furthermore, external factors like a national ICT strategy and other different strategies in the institute have also an effect on the adaptation of the innovation. Different networks may foster the integration of ICT in education like collaboration between schools, and educational institutions, as well as connections with working life. The contextuality of the implementation is another important aspect in this research.

As discussed above, the ICT use involves both possibilities and challenges that teachers need to face in their practice. One perspective to promoting ICT use is to discuss the properties of an ICT tool approached here from the point of view of its usability. Usability of an artefact, in general, indicates to what extent people can employ an artefact in order to achieve a particular goal, i.e., the goals the designers of the artefact have been set as a goal for the use of the artefact. In human-computer interaction and computer science, usability usually refers to the elegance and clarity with which the interaction with a computer programme or a web site is designed (Nielsen, 1993). Nielsen has approached the concept of usability from the perspective of adoption and acceptability of an artefact. Following him, practical usability of an artefact could be defined through five quality components:

a) *learnability*, i.e., how easy it is for users to use a new artefact.
b) *efficiency*, i.e., how quickly a user can perform tasks (organise learning activities) once they have learned to use the artefact.
c) *memorability*, i.e., how easily a user could re-establish proficiency when returning to use the artefact.
d) *error-free*, i.e., how few errors users make when using the artefact.

e) *satisfaction*, i.e., how pleasant it is to use the artefact or how easy it is to change elements (avoidance of monotony) or modify the artefact individually.

Consequently, usability is a quality attribute concerning how easy it is for a user to accept or to start using the artefact. In the case of pedagogical innovations, it is appropriate to evaluate also pedagogical usability in addition to the technical usability dimension. Pedagogical usability of an ICT tool can be approached by analysing what kind of learning and development of motivation the use of the ICT tool creates. Motivation describes the factors within an individual which arouse, maintain and channel behaviour towards the aims of the learning activity and could be conceptualised based on the *Self-Determination Theory* (SDT) (Deci & Ryan, 2004). Central to SDT is the concept of basic psychological needs that are assumed to be innate and universal. These needs are the *need for autonomy*, the *need for competence*, and the *need for relatedness (need to belong to a group)*. Furthermore, the *interest* of the student in a learning activity can be added to these needs. Consequently, a pedagogically usable ICT tool could facilitate learning and increase the motivation of a learner in a learning activity.

In all, pedagogical usability of the ICT tool could be defined by six components through evaluating how the learning activity is supported:

a) *students' activity and intentions*: how students are guided to
   - take responsibility over their own learning
   - set goals (together with a teacher)
   - proceed according to the plan to reach the goals they set
   - plan by themselves or in small co-operative groups
b) *students' knowledge construction*: how students are guided to
   - combine their previous knowledge with the new topics to be learnt
   - tailor information structures that they can comprehend
c) *students' collaboration and interaction*: how students are guided to
   - actively take part in group activities and support each other by discussing and sharing knowledge
   - explaining, debating, and questioning
   - share ideas.
d) *students' self-evaluation and reflection*: how students are guided to
   - test their ideas
   - self-evaluating activities
   - examine their own learning (reflection)
   - develop meta-cognitive skills or skills which guide and regulate their learning?
e) *contextualisation of the learning environment*: how students are guided to
   - engage in learning in real life situations or in situations simulating real-life instances?
f) *student motivation*: have a positive effect on student's
   - feeling of autonomy, competence and social relatedness
   - interest in the content or a learning task
   - enjoyment or values

In Figure 1, we summarise the usability of an ICT tool. The main distinction here is pedagogical usability (Nielsen, 1993) versus technical usability. The former is in relation to the conventions of teaching a particular school subject, cultural constrains and affordances such as the pedagogical orientation of the teacher and beliefs about the usability of an ICT tool, administrative leadership and support, and external factors such as funding, in-service training, and collaborative partnership with outside organisations. The latter is related to technical aspects of the ICT tool, the possibilities opened up by using a particular ICT tool, i.e., what kinds of physical constrains and affordances the ICT tool has.

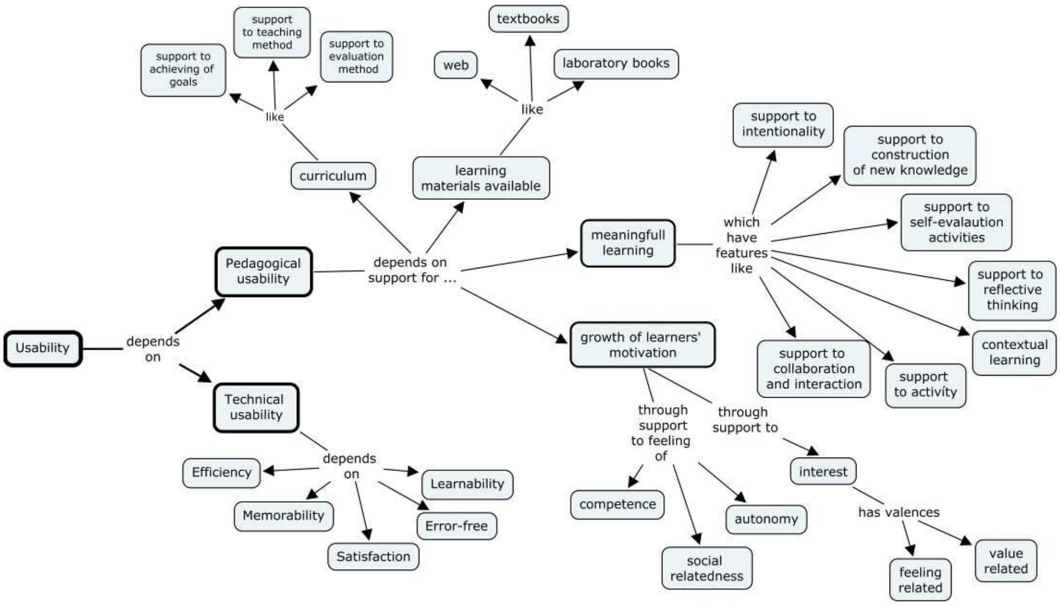

Figure 1. The usability of an ICT tool approached through pedagogical and technological aspects

As discussed above, usability of an ICT tool in education is a complex concept, and therefore, analysis should take into account the users of the ICT tool and their needs, the educational context regarding the curriculum, available learning materials, and implementation in the classroom, which we attempt to address in the following analysis of needs.

ANALYSIS OF NEEDS

In order to clarify the needs and constrains regarding the use of ICT in science education, an international survey within six participating countries (Austria, Bulgaria, Finland, France, German, Greece) was designed and carried out. The aim of the survey was to gain insights into the spectrum of possible conditions, needs and actual practices in using ICT in science classrooms, and to get the specific information needed to construct a teacher training course close to the conditions in schools in different European countries and their local contexts. Therefore, the questionnaire was aimed at three major groups: science teachers actively involved in science education, staff members involved with school management who are influential to the general infrastructure, and computer administrators responsible for the technical support in the schools. The needs and constraints stated by teachers regarding their teaching and in-service teacher education courses were our main interest. More than 50 teachers from each of the six partner countries, altogether 854 teachers, answered the survey. The results of the survey were presented and considered at the second project meeting in order to have a solid basis for creating the different course modules (Welzel-Breuer et al., 2009).

Here, we highlight a few themes brought up in the data that are especially interesting for the course module regarding the usability of an ICT tool. First, teachers tend to use ICT in their classroom with different intensity depending on nationality. Finnish and French participants informed that they integrate ICT use in their teaching often or daily, whereas Greek teachers stated that they are likely to use it seldom or never. In addition to the notion of various cultures of using ICT in daily schooling, difference between the sexes was in favour to men who used ICT more often. Second, confidence and competence of a teacher as a user of ICT in the classroom seem to be intertwined with each other. The feeling of being a competent user of ICT in science education was in relation with attitudes towards ICT use in general, i.e. the more confident the users regard themselves the more positive conceptions they have about benefits and added value of the use. According to the responses to the open questions of the survey, the possibilities to increase student interest and motivation in science learning, support students' autonomy or active learning were seen as the most positive features of using ICT in the classroom. Furthermore, it is rather natural that the teachers who have a competent view of themselves as users let their students use ICT in the classroom more often.

The survey was to gain also an insight into teachers' needs as users of ICT in their school work and they were asked to describe their needs regarding the professional development in ICT use. Teachers wished to get acquainted with some 'best practice examples', i.e. with ICT tools recommended by other users, and to have a chance to test provided tools and materials with the possibility to share experiences with their peers. It seemed also that they wished to have support for choosing ICT tools to be used in the classroom as well as to understand the basic principles of pedagogical decision-making. In addition to pedagogical issues, technical issues related to ICT use, for example difficulties in learnability, were mentioned as the most negative aspects in using ICT. Altogether, the need to be aware of various aspects of using ICT in a science classroom and to have support for choosing an appropriate tool for the classroom were brought up.

Since the teachers seem to have a need to build up readiness for using ICT in general as well as in science education particularly, we conclude that usability should be introduced for the teachers not only through technical but also through pedagogical aspects of usability. For example, technical usability of an ICT tool could be approached through quality components, like learnability. Furthermore, the issues related to learning and motivation should be considered in discussing pedagogical viewpoints. The aspects of confidence and competence are intertwined with each other, and therefore, the course needs to address both aspects.

DESIGN SOLUTION: AIMING AT ADDRESSING THE NEEDS IN THE FIELD

In this paper, we discuss the course module that aims at helping a science teacher to choose and adopt usable ICT tools for use in the classroom. In order to enhance this potential, the module comprises of four sub-modules which approach usability from different perspectives: (1) content related and technical usability, (2) usability especially in the case of multimedia, (3) pedagogical usability, and (4) motivational issues related to usability. The challenge in designing the course is to take into account the complexity of usability due to various related aspects. The structure of the module is not to cover all possible aspects but to provide a starting-point for approaching usability issues. The objectives of the course module are presented in Table 1.

Table 1. The objectives of the course module focusing on usability of ICT tools in science education

The overall aim of the module:
A teacher should be able to choose ICT tools for learning activities while taking usability into consideration in various ways.

Sub module 1. Content related and technical usability	*Sub module 2.* Usability of multimedia	*Sub module 3.* Pedagogical usability	*Sub module 4.* Motivational usability
A learner is familiar with and is able to take into account science content related and technical issues when selecting an ICT tool for a leaning activity.	A learner is familiar with and is able to take into account issues related to usability of multimedia when selecting an ICT tool for a leaning activity.	A learner is familiar with and is able to take into account learning related issues when selecting an ICT tool for a leaning activity.	A learner is familiar with and is able to take into account motivational issues when selecting an ICT tool for a leaning activity.
Contents in this sub-module are provided in two separate parts: *technical* and *content related usability*. A learner will - acquaint him or herself with issues related to technical and content related usability on the basis of research-based knowledge and literacy. Usability will be introduced through some main concepts regarding these two themes. -apply such knowledge in assessing some examples ('best practice examples' or the learner's own examples).	A learner will - acquaint him or herself with theoretical aspects regarding learning with media as part of teaching and learning science. Especially, a learner will be able to discuss learning theories special to the use of media, (like cognitive load, dual channel) - apply such knowledge in assessing some examples ('best practice examples' or the learner's own examples).	A learner will - acquaint him or herself with theoretical aspects regarding the learning process with ICT tools, students' activity and intentions, students' knowledge construction, students' collaboration and interaction, students' self-evaluation and reflection, and moreover diagnostic and formative evaluation contextualisation of the learning environment - apply such knowledge in analysis of particular examples of ICT use in science teaching and learning ('best practice examples).	A learner will - acquaint him or herself with theoretical aspects of motivation, for example with intrinsic and extrinsic motivation. In addition, a learner will get to know about basic psychological needs: need for autonomy, competence and social relatedness, and issues about what makes the topic interesting - learn about how to evaluate activity motivation by an inventory and to include motivating features in a learning activity

The overall aim of the course module is to provide activities for further professional development in two ways. First, the underlying idea is that a teacher should become aware of different perspectives of usability. For example, a teacher should acquaint him or herself with technical and content related issues, which can be seen to form criteria for assessing ICT tools available for science teaching and learning in the classroom. Since the usability and appropriateness of a particular ICT tool is related with the learning objectives in the classroom, the idea of usability is not to evaluate ICT tools as such. A teacher should become aware of the aspects according to which different tools and applications can be discussed. However, assessing and choosing the tools to be used in the classroom are always case-specific.

Second, since usability is something relative and dependent on the aims set for learning and the needs of a teacher, a teacher should be proficient in assessing and choosing ICT tools in general. The basic knowledge is not enough, and therefore ability to apply such knowledge in practice is needed as well. In the course module, the aim is not only to focus on basic information about usability but also to provide activities through which teachers can apply and integrate their knowledge in practice. The 'best practice examples' are to be discussed from various perspectives of usability. In that way, teachers get familiar with some new technological innovations, in accordance with their wishes stated in the survey, and even more importantly, they learn also how to apply their knowledge in various situations. The implementation of the course module includes both an e-learning phase and face-to-face meetings. In this way, the interactive and cooperative learning process includes discussions and possibly the sharing of experiences. Consequently, teachers attending the course can benefit from intercultural perspectives.

DISCUSSION

We have described the first phases of designing a teacher education course with the aim of enhancing science teachers' readiness for using ICT as part of their teaching. The focus of the paper was on the course module especially concerning usability and perspectives that a science teacher should take into account when choosing ICT tools to be used in the classroom. In accordance with the principles of design-based research (DBR), theoretical problem analysis and the need assessment of different actors have been carried out as the first step of the design process (see Design-Based Research Collective, 2003). In what follows, we discuss the course design reflecting on the needs and problems that are to be addressed.

First, various aspects associated with usability of ICT tools need to be taken into consideration when structuring the course module. We decided to concentrate on four subsets when considering usability. The idea was not to cover all possible aspects or design an overall framework of usability but to provide teachers with a starting-point for knowledge building using clear aspects which are relevant from the point of view of their work. The basic knowledge about usability can be considered as a way of enhancing professional readiness for pedagogical use of ICT tools. Even if a teacher is skilful in using ICT in general, for example for personal purposes, the pedagogical perspective needs a different orientation. Teachers need to gain some meta-level skills and knowledge about ICT use for educational purposes. Therefore, the module is to provide activities for applying the knowledge in practice as well.

Second, it is widely agreed that using ICT opens up new opportunities in teaching and learning science. Consequently, teachers need to commit themselves to professional development in order to be able to benefit from new opportunities and possibly renew their pedagogical views of science education. We do not claim that the way of teaching and learning science is to be changed totally, but so-called traditional methods need to be reconsidered. During the course, we would like to introduce to teachers some good examples and discuss conditions for their appropriate use through usability aspects. Teachers need to have good experiences of using ICT and positive ideas supported by experts in order to strengthen their feeling of competence.

Third, the challenge is to influence the attitudes that teachers have towards ICT tools as part of education. The critical point is whether a teacher integrates an innovation with classroom activities (Rogers, 2003). In the course module, motivation can be seen to be taken into consideration through three basic notions stated by Deci and Ryan (2004). The idea is to provide a solid basis for professional readiness including some knowledge and skills. In addition to the feeling of competence, teachers have an active role in the course and they are supposed to cooperate with each other.

Fourth, we have distinguished pedagogical and technical usability (Nielsen, 1993) to address the different needs indicated in the survey. In this way, teachers also become aware of different aspects that are essential in assessing usability. In addition, especially with the help of the module focusing on professional development, teachers will gain analytical tools for reflecting on their experiences and possible problems that they will face when using ICT in their classrooms.

Naturally, it is not possible to address all needs and problems that emerge in the initial analysis of the field. The course design is an attempt to face the various needs within the practical constraints. In the next phase of the developmental work, the course design will be partly tested and improved based on practical experiences and feedback. Different perspectives are needed to gain a broader insight, and therefore, teacher educators, teachers involved with testing the course material and researchers involved with the project are necessary in this process. Furthermore, since the course is for science teachers representing various European countries, intercultural perspectives and flexibility need to be considered as well.

ABSTRACT

Science curriculum in Malaysia gives conscious emphasis on the acquisition of scientific skills and thinking skills, the inculcation of scientific attitudes and noble values besides the acquisition of scientific and technological knowledge and its application to the natural phenomena and students' daily experiences. As pointed out by Renner and Philips (1980): 'The purpose which runs through and strengthens all other educational purposes– the common thread of education is the development of the ability to think'. The purpose of this study is to gauge the disposition towards critical thinking among Form 4 rural secondary students in the Interior Division of Sabah, Malaysia. This study is also aimed to ascertain if there is any significant difference in students' disposition towards critical thinking based on their gender and types of classes attended. This is a non-experimental quantitative research and sample survey method was used to collect data. Research samples were selected by using a two-stage cluster random sampling technique. The California Critical Thinking Disposition Inventory (CCTDI) was adopted to measure the key theoretical aspects of the overall dispositional dimension of critical thinking. The seven CCTDI scales measured were 'Truth-Seeking', 'Open-Mindedness', 'Analyticity', 'Systematicity', 'CT Self-Confidence', 'Inquisitiveness', and 'Maturity'. Independent samples *t*-test was used to test the stated null hypotheses at a specified significance level, alpha = .05. The research findings will bring some meaningful implications to those who are involved directly or indirectly in the development and implementation of science curriculum especially in the Interior Division of Sabah, Malaysia.

Keywords: *Disposition towards critical thinking*

BACKGROUND OF THE STUDY

Since education is a principal means of preparing students for an active and responsible life within a technologically-based society, school at all levels should become the focus for the fostering and development of critical thinking. According to Nelson (1994), "Enabling students to think critically is one of the central objectives of liberal and professional education." Critical thinking in education calls on students to evaluate their own thought process (Kalman, 2002). Critical thinking accompanies a movement in education toward inquiry-based or problem-based learning. According to Schamel and Ayres (1992), "students learn best by doing," or preparing their own questions based on their observations rather than participating in a "predetermined exercise with a forgone conclusion." Students are fully engaged in learning and cooperative group learning helps students interact with one another (Ahern-Rindell, 1998).

Hence, a current theme in science teaching reform is the emphasis on active, inquiry-based teaching and learning (National Research Council, 1996). Inquiry-based learning is a method of instruction focusing on the student and their ability to design a process for use in solving a problem, requiring higher levels of cognition. While inquiry-based learning takes the focus away from memorization of specific scientific concepts, there is supporting evidence that students learn as much “factual” information as they would in a traditional lecture/lab setting. However, inquiry students tend to retain the information longer and usually experience higher self-efficacy and process skills than students in traditional science courses. The case has been made for teaching critical thinking skills in school. Science classrooms provide many opportunities for inquiry-based or problem-based learning. However, in order for this inquiry-based learning to happen, changes must take place in science classrooms to move away from rote and passive application of learned formulas toward the use of critical thinking as the primary tool of learning (Zoller, Ben-Chaim, and Ron, 2000).

In consonance with the National Education Philosophy, science education in Malaysia nurtures a Science and Technology Culture by focusing on the development of individuals who are competitive, dynamic, robust and resilient and able to master scientific knowledge and technological competency. Hence, science curriculum in Malaysia gives conscious emphasis on the acquisition of scientific skills and thinking skills, the inculcation of scientific attitudes and noble values besides the acquisition of scientific and technological knowledge and its application to the natural phenomena and students’ daily experiences (Curriculum Development Centre, 2001).

Thinking is a mental process that requires an individual to integrate knowledge, skills and attitude in an effort to understand the environment. One of the objectives of the Malaysian national education system is to enhance the thinking ability of students. This objective can be achieved through a curriculum that emphasizes thoughtful learning. Teaching and learning that emphasizes thinking skills is a foundation for thoughtful learning. Thoughtful learning is achieved if students are actively involved in the teaching and learning process. Activities should be organized to provide opportunities for students to apply thinking skills in conceptualization, problem solving and decision-making (Curriculum Development Centre, 2001).

In Malaysian context, thinking skills are categorized into critical thinking skills and creative thinking skills. A person who thinks critically always evaluates an idea in a systematic manner before accepting it. On the other hand, a person who thinks creatively has a high level of imagination, is able to generate original and innovative ideas, and modify ideas and products. Thinking strategies are higher order thinking processes that involve various steps. Each step involves various critical and creative thinking skills. The ability to formulate thinking strategies is the ultimate aim of introducing thinking activities in the teaching and learning process (Curriculum Development Centre, 2001).

PROBLEM STATEMENT

Despite the emphasis on the acquisition of thinking skills among students, there have not been many well-documented research which aimed to gauge the disposition towards critical thinking among Form 4 rural secondary students especially in the Interior Division of Sabah, Malaysia. The possible differences in the disposition towards critical thinking based on students’ gender and types of classes attended have not been well-investigated and documented. Due to the scarcity of well-documented research in this field of study, this proposed study is aimed to gauge the disposition towards critical thinking among Form 4 rural secondary students and to determine if there is any significant difference in the disposition towards critical thinking based on students' gender and types of classes attended.

RESEARCH QUESTIONS

This study attempts to answer the following questions:-

i) What is the disposition towards critical thinking among Form 4 rural secondary students in the Interior Division of Sabah?

ii) Is there a significant difference in the disposition towards critical thinking based on students' gender?

iii) Is there a significant difference in the disposition towards critical thinking based on type of classes attended?

DEFINITION OF TERMS

Some of the terms used in study are defined as follows:

Terms	Definitions
Disposition	the attitudinal basis for the internal motivation to think critically. It is the tendency to do something or to have or develop something (Facione *et al*. 2000).
Critical thinking	the process of purposeful, self-regulatory judgment which involves cognitive skills as well as affective dispositions (Facione, 1990).
Truth-Seeking (the T-Scale)	targets the disposition of being courageous when asking questions, eager to seek best knowledge in a given context, and honest in the pursuit of inquiry even if the findings do not support one's interests or one's preconceived opinions. The truth-seeker would rather pursue the truth rather than win the argument. (Facione, 1990)
Open-Mindedness (the O-Scale)	targets the disposition of being open to and tolerant of the expression of divergent points of view with sensitivity to the possibility of one's own bias. The open-minded person respects the right of others to hold differing opinions. (Facione, 1990)
Analyticity (the A-Scale)	targets the disposition of being alert to potentially problematic situations, anticipating possible results or consequences, and prizing the application of reason and the use of evidence even the problem at hand turns out to be challenging or difficult. The analytically inclined person is alert to potential difficulties, either conceptual or behavioral, and consistently looks to anticipatory intervention, reason-giving and fact-finding as effective ways to resolve matters. (Facione, 1990)
Systematicity (the S-Scale)	targets the disposition toward organized, orderly, focused, and diligent inquiry. No particular kind of organization, e.g. linear or non-linear, is given priority on the CCTDI. The systematic person strives to approach specific issues, questions or problems in an orderly, focused, and diligent way, however, that might be accomplished. (Facione, 1990)
CT Self-Confidence (the C-Scale)	refers to the level of trust one places in one's own reasoning processes. CT self-confident persons trust themselves to make good judgments and believe that others trust them as well, since they believe others look to them to resolve problems, decide what to do, and bring reasonable closure to inquiry. (Facione, 1990)
Inquisitiveness (the I-Scale)	measures one's of intellectual curiosity. The inquisitive person is one who values being well-informed, wants to know how things work, and values learning even if the immediate payoff is not directly evident. (Facione, 1990)
Maturity (the M-scale)	targets how disposed a person is to make reflective judgments, particularly under conditions of uncertainty. The maturity scale addresses cognitive maturity and epistemic development. CCTDI scoring gives preference to those disposed to approach problems, inquiry, and decision making with a sense that some problems are ill-structured, some situations admit of more than one plausible option, and many times judgments must be made based on standards, contexts and evidence which preclude certainty. (Facione, 1990)

METHODOLOGY

Research Design

This is a non-experimental quantitative research. Non-experimental research is a systematic empirical inquiry in which the researcher does not have direct control of independent variables because their manifestations have already occurred or because they are inherently not manipulable. Hence, inferences about relations among variables are made, without direct intervention, from concomitant variation of independent and dependent variables (Johnson & Christensen, 2000). Sample survey method was used to collect data. In this study, the California Critical Thinking Disposition Inventory (CCTDI) was used to gauge students' disposition towards critical thinking.

Location of the Study

This study was conducted in 18 Form 4 classes of nine randomly-selected rural secondary schools in the Interior Division of Sabah, Malaysia. The distribution of schools and Form 4 classes according to four districts in the Interior Division of Sabah is shown in Table 1.

Table 1: Distribution of Schools and Form 4 Classes according to Four Districts in the Interior Division of Sabah, Malaysia

District	Number of Schools	Number of Form 4 Classes
Tambunan	2	4
Keningau	4	8
Tenom	2	4
Nabawan	1	2
Total	9	18

Research Samples and Sampling Method

The population of this study was Form 4 students from 22 rural secondary schools in the Interior Division of Sabah. The population size is approximately 3,500 students. The average age of the population is 16 years old. Sample size of this study was determined based on the formula suggested by Krejcie and Morgan (1970) and power analysis (Miles & Shevlin, 2001). Hence, sample size used in this study is considered adequate as compared to Krejcie and Morgan's recommendation which is a sample size of 346 for the population size of 3,500.

To be specific, a two-stage cluster random sampling technique was used to identify nine rural secondary schools and 18 Form 4 classes to be involved in this study. At stage one, systematic sampling technique was used to identify nine secondary schools from all the 22 secondary schools in the Interior Division of Sabah. After nine schools have been identified, simple random sampling technique was used to identify any two Form 4 classes from each of the chosen schools by using a random number table. All students in the chosen classes were automatically taken as the samples of the study. This combination of sampling techniques is to ensure the representativeness of the research samples.

Instrumentation

The California Critical Thinking Disposition Inventory (CCTDI) was adopted to gauge the disposition towards critical thinking among Form 4 rural secondary students in the Interior Division of Sabah, Malaysia. Each item on the CCTDI targets one of the seven dispositions toward CT i.e. Truth-Seeking, Open-Mindedness, Analyticity, Systematicity, CT Self-Confidence, Inquisitiveness, and Maturity.

CCTDI responses are registered using a forced-choice Likert scale that requires the respondent to either agree or disagree with each item. Respondents with a negative disposition toward CT earn 1, 2, or 3 points per item, while respondents with a positive disposition toward CT earn 4, 5 or 6 points per item. There is no middle choice. Hence, selecting the response consonant with a positive disposition toward CT will yield 4 or more points. However, selecting the response in opposition to that disposition will yield 3 points or less.

Each scale score is derived from the set of items that target that scale. For each item, there is a response, either "agree" or "disagree", conceptually associated with strength in the disposition that the item targets. Each scale addresses an individual and essential component of the critical thinker's habits of mind, and no individual disposition can be dismissed as less important to nurture. On the other hand, it should not be presumed that an individual who scores well on any given CCTDI scale can be predicted to have strong scores across all seven CCTDI scales. The Cronbach's alpha reliability coefficient of CCTDI used in this study was acceptable at 0.659.

Data Collection Procedures

Before administering the instrument, formal permission from the principals of the schools involved was sought and obtained. The California Critical Thinking Disposition Inventory (CCTDI) was administered by the researcher. In relation to this, students were gathered in the school hall and the instrument was administered to the students concurrently. The students were told about the nature of the instrument and how the instrument should be answered.

Data Analysis Procedures

Descriptive statistics were used to describe the disposition towards critical thinking among Form 4 rural secondary students in the Interior Division of Sabah. Among the descriptive statistics used were percentages, mean, average item mean, standard deviation, average item standard deviation and range. The CCTDI offers eight scores: the seven scale scores and the overall CCTDI total score. Each scale score ranges from 10 up to 60. In relation to this, the 'CCTDI Scale Standardization Table' was used to convert these item points into 10 to 60 point scale scores. Total possible scores range from 70 up to 420. The recommended cut score for each scale is 40 and the suggested target score is 50. Respondents who score above 50 on a scale are strong in that dispositional aspect. A scale score between 40 and 30 indicates ambivalence toward that disposition. Any score below 40 could be considered weak at best, since scoring below 40 requires responding to some items negatively. Respondents who score below 30 on a given scale are negatively disposed in that CT dispositional aspect. Scoring below 30 indicates that, on average, the respondent responds in opposition to the CT dispositional aspect measured by a given scale. An overall CCTDI score of less than 280 could be used as a cutoff indicator of overall deficiency in the disposition toward CT. Similarly, an overall score of 350 or more could be used as a general indication of across the board strength in the disposition toward CT.

On the other hand, as an effort to ensure all the quantitative data were drawn from a normally distributed population, graphical measures such as histogram, stem-and-leaf plot, normal Q-Q plot and detrended normal Q-Q plot were plotted for each of the variables studied. Furthermore, numerical measures such as skewness and kurtosis were used to identify any deviations from normal distributions (Hair, Anderson, Tatham, & Black, 1998; Miles & Shevlin, 2001). After the assumptions of using parametric techniques in analyzing quantitative data were met, independent-sample *t*-test was used to test the stated null hypotheses at a predetermined significance level, alpha = .05.

Independent Sample t-Test

Independent sample *t*-test was used to determine whether there is a significant difference in the disposition towards critical thinking between male and female Form 4 rural secondary students in the Interior Division of Sabah. The same statistical test was also used to ascertain the significant difference in the disposition towards critical thinking based on types of classes attended.

RESEARCH FINDINGS AND DISCUSSION

Students' Disposition towards Critical Thinking

Table 2 shows the mean and standard deviation of students' disposition towards critical thinking (overall and each of the seven subscales respectively).

Table 2: Mean and Standard Deviation of Students' Disposition towards Critical Thinking according to CCTDI Subscales

Subscales	Number of Items	*n*	Mean	Average item mean[a]	*SD*	Average Std. Dev.	Range
Truth-Seeking	12	402	41.46	3.455	6.39	.533	27-60
Open-Mindedness	12	394	49.38	4.115	5.55	.462	27-60
Analyticity	11	402	43.94	3.994	5.85	.532	21-59
Systematicity	11	403	47.46	4.314	6.31	.574	28-60
CT Self-Confidence	9	402	37.07	4.119	4.65	.517	22-49
Inquisitiveness	10	404	46.74	4.674	5.76	.576	25-60
Maturity	10	400	36.27	3.627	4.84	.484	21-53

[a]Average item mean = Scale mean divided by the number of items in a scale

As shown in Table 2, the overall mean of disposition towards critical thinking (Mean = 302.91) indicated that students are ambivalently disposed towards critical thinking. Based on the mean value of each scale score, it can be concluded that students are positively disposed towards 'open-mindedness' (Mean = 49.38), 'systematicity' (Mean = 47.46), 'inquisitiveness' (Mean = 46.74), 'analyticity' (Mean = 43.94), and 'truth-seeking' (Mean = 41.46). However, students are ambivalently disposed towards 'CT self-confidence' (Mean = 37.07) and 'maturity' (Mean = 36.27). Based on the average item mean, the disposition towards critical thinking in descending order is 'inquisitiveness', 'systematicity', 'CT self-confidence', 'open-mindedness', 'analyticity', 'maturity' and 'truth-seeking'. Table 3 shows the percentages of students according to scale scores and overall scores of disposition towards critical thinking.

Table 3: Percentages of Students according to Scale Scores of Disposition towards Critical Thinking

Subscales	Nos. Items	*n*	Scale Scores		
			10-30 Negative Disposition	31-39 Ambivalent Disposition	40-60 Positive Disposition
Truth-Seeking	12	402	2.7	35.9	61.3
Open-Mindedness	12	394	.3	3.4	96.4
Analyticity	11	402	2.0	18.2	79.9
Systematicity	11	403	.5	10.9	88.6
CT Self-Confidence	9	402	8.0	61.8	30.2
Inquisitiveness	10	404	.2	12.6	87.1
Maturity	10	400	8.8	65.8	25.5
			Overall Scores		
			< 280 Negative Disposition	281-349 Ambivalent Disposition	350> Positive Disposition
Overall	75	370	13.8	85.4	.8

Mean Difference in the Disposition towards Critical Thinking between Male and Female Form 4 Rural Secondary Students in the Interior Division of Sabah

The first and second null hypotheses were tested by using the Independent sample *t*-test at a predetermined significance level, alpha = .05. As shown in Table 4, independent sample *t*-test results showed that there is no significant difference in the overall disposition towards critical thinking between male and female rural secondary students in the Interior Division of Sabah (t = -1.549, p = .122). In relation to this, female students are not more disposed towards critical thinking as compared to their counterparts.

Table 4: Mean Difference in the Disposition towards Critical Thinking based on Students' Gender

Subscales	Gender	*n*	Mean	*SD*	Mean Difference	Effect Size	*t*	*df*	*p*
Truth-Seeking	Male	123	41.27	6.436	-.27	-.04	-.389	400	.698

Maturity	9.0	68.9	22.1	8.6	64.4	27.0
	Male			Female		
	<280 Negative Disposition	281-349 Ambivalent Disposition	350> Positive Dispositon	<280 Negative Disposition	281-349 Ambivalent Disposition	350> Positive Disposition
Overall	15.8	82.5	1.8	12.9	86.7	.4

In relation to this, gender as a predictor of critical thinking skills or dispositions was a variable that has been evaluated by nearly all of the critical thinking studies. Wilson (1989) studied the critical thinking ability of entering college freshmen using the Watson-Glaser test and ACT College Reports. He found that gender was a significant predictor on critical thinking skill. Costa, McCrae's and Sanchez's study (as cited in Facione, Giancarlo *et al*. 1995) found that females were more open-minded and mature in their thinking, while males were more analytical. Walsh (1996) conducted a study of 499 male and female undergrads and found that gender was a predicting variable on the variance in critical thinking disposition. In a study of College of Agricultural and Life Sciences undergraduates at the University of Florida that evaluated learning style and critical thinking disposition, Rudd, Baker *et al*. (2000) found significant gender differences (alpha = .03) for scores of the CCTDI. However, there have been just as many studies indicating the null nature of gender effect on critical thinking. For example, in developing and validating an instrument to evaluate critical thinking skills of nurses, gender and ethnicity were found to be independent of critical thinking skills (Claytor 1997).

Hence, the role of gender has not been as conclusive. Some studies have shown gender to not be related to critical thinking skills (Claytor 1997), while other studies have found a significant relationship between gender and critical thinking skills (Rudd, Baker *et al*. 2000; Walsh 1996; Wilson 1989).

Mean Difference in the Disposition towards Critical Thinking between Science and Non-Science Form 4 Rural Secondary Students in the Interior Division of Sabah

Table 6: Mean Difference in the Disposition towards Critical Thinking based on Types of Classes Attended
